- D106: Since "-21" is a numerical value, it is converted to a binary value.

This type of file in which the number of columns vary with individual rows cannot be created by Excel. It is created when the CSV file is modified by a user.

- When the specified number of columns is set to a value other than 0, a CSV format file is read as the table with the specified number of columns. The elements outside the specified number of columns are ignored.

**Ex.**

When "Reading data after converted to CSV format" (Decimal (16-bit data)) is specified and the number of columns is set to a value other than 0 ((d1)+6 is set to 2)

[Data created in Excel]

|   | A             | B   | C              |
|---|---------------|-----|----------------|
| 1 | Main/sub item |     | Measured value |
| 2 | Length        | 1   | 3              |
| 3 | Temperature   | -21 |                |
| 4 |               |     |                |

[Data saved in CSV format]

|               |   |     |                |    |    |
|---------------|---|-----|----------------|----|----|
| Main/sub item | , | ,   | Measured value | CR | LF |
| Length        | , | 1   | , 3            | CR | LF |
| Temperature   | , | -21 |                | CR | LF |

(1)

[Data to be loaded to the device]

|          |    |    |     |        |     |    |
|----------|----|----|-----|--------|-----|----|
| SP.FREAD | U0 | K2 | D10 | "ABCD" | D99 | M0 |
|----------|----|----|-----|--------|-----|----|

| D10 | 0100H |
| D11 | -     |
| D12 | K6    |
| D13 | K0    |
| D14 | K0    |
| D15 | K0    |
| D16 | K2    |
| D17 | K0    |

[Loaded data]

|      |      |
|------|------|
| D99  | K6   |
| D100 | K0   |
| D101 | K0   |
| D102 | K0   |
| D103 | K1   |
| D104 | K0   |
| D105 | K-21 |

(1) The elements outside the specified number of columns are ignored.

(2) Loaded data

(3) File name

(4) Control data

D10: Execution/completion type

D11: Completion status

D12: Number of read-target data

D13: Maximum number of read data

D14, D15: File position

D16: Number of columns

D17: Data type specification

D99: Number of data actually read

D100: Since "Main/sub item" is not a numerical value, the conversion data, 0, is stored.

D101: Since " " is not a numerical value, the conversion data, 0, is stored.

D102: Since "Length" is not a numerical value, the conversion data, 0, is stored.

D103: Since "1" is a numerical value, it is converted to a binary value.

D104: Since "Temperature" is not a numerical value, the conversion data, 0, is stored.

D105: Since "-21" is a numerical value, it is converted to a binary value.

- When the number of columns differs in each row, the elements outside the specified number of columns are ignored and 0 is added to the cells where no element exists.

**Ex.**

When the number of columns differs in each row

[Data saved in CSV format]

|               |    |     |                |    |        |    |    |

| D99  | K6   |
| D100 | K0   |
| D101 | K0   |
| D102 | K0   |
| D103 | K0   |
| D104 | K0   |
| D105 | K-21 |

- When "Reading data after converted to CSV format" is specified, data can be divided and read.

[Specify row to start reading]

- Execution/completion type: Reading data after converted to CSV format (Decimal (16-bit binary data))
- Number of columns specification: 4H
- Data type specification: Words
- File position: 2H
- Read start device: D0
- Number of data actually read: 6H

- (1) Starting row  
 (2) Next starting position  
 (3) Data in the device (loaded data)  
 N: Number of data

[Reading data from the position where the previous reading ends]

- Execution/completion type: Reading data after converted to CSV format (Decimal (16-bit binary data))
- Number of columns specification: 4H
- Data type specification: Words
- File position: FFFFFFFFH (continuing from the position where the previous reading ends)
- Read start device: D7
- Number of data actually read: 5H

- (1) Starting row  
(2) Next starting position  
(3) Data in the device (loaded data)  
N: Number of data

**Point**

- When reading data from the position where the previous reading ends, specify the same values for "Execution/End type", "Number of columns", and "Data type specification". If not, data cannot be added correctly from the position where the previous reading ends.
- While reading data from the position where the previous reading ends, if the SP.FREAD instruction with different settings or the SP.FWRITE instruction is executed, data cannot be added correctly from the position where the previous reading ends.

## Precautions

- Do not execute this instruction in interrupt programs. Doing so may cause malfunction of the module.
- When reading multiple elements at reading data after converted to CSV format, secure devices sufficient for the total size of the elements in the read data area before executing the instruction. Since read data is stored from (d2)+1, the number of words required to be secured as (d2) is ((total number of words for each element) + 1) words.
- When "Reading data after converted to CSV format" (String (ASCII data)) is specified, set the total size (in units of words) to (d1)+3 (Maximum number of read data).  
 [Example] When reading 100 elements each of which contains 100 characters from a CSV file  
 $(100 \text{ (characters)} + 2 \text{ (NULL)}) \times 100 \text{ (elements)} = 10200 \text{ bytes} = 5100 \text{ words}$   
 Therefore, set 5100 to (d1)+3 to secure an area for 5101 words for (d2).
- Since the SP.FREAD instruction causes file reading, the scan time may be extended when this instruction is executed.
- The SP.FREAD instruction does not support character codes with BOM. If a file that uses a character code with BOM is executed, unintended data will be read. To read a CSV file with BOM that was created using Excel, use an application such as a text editor to change the character code to exclude BOM.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | Data is read exceeding the size of the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3285H            | The drive specified by (s1) is not the one for the SD memory card.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

If the SP.FREAD instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 663 Error codes generated for file operation instructions

# Writing data to the specified file

## SP.FWRITE

This instruction writes device data to the specified file in an SD memory card.

| Ladder | ST                                   |
|--------|--------------------------------------|
|        | ENO:=SP_FWRITE(EN,U,s1,s2,s3,d1,d2); |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| SP.FWRITE   |                     |

### Setting data

### Descriptions, ranges, and data types

| Operand | Description                                                | Range                        | Data type      | Data type (label)                       |

| +7            | Data type specification         | • 0: Word<br>• 1: Even number of bytes*1<br>• 2: Unit of the data type specified by (d1)+0<br>• 3: Odd number of bytes*1*2<br>"0: Word", "1: Even number of bytes", and "3: Odd number of bytes" can be specified only when "0000H: 16-bit binary data" or "0100H: Decimal (signed 16-bit data)" is specified by (d1)+0.                                                                                                                                                                                                                                                                                       | 0, 1, 2, 3                                                                                      | User   |

\*1 When "1: Even number of bytes" or "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), the setting range of (s3)+0 (Number of request write data) is 1 to 32767.

\*2 Even when "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), specify the number in units of words. Add one byte to the odd number of bytes to be written and set the number in (s3)+0 (Number of request write data).

\*3 Enabled only when "Converting and writing data in CSV format" is specified by (d1)+0 (Execution/completion type), and when "Added to the end of the file" is specified by (d1)+4 and (d1)+5 (File position). Otherwise, an error will occur.

## ■File name (s2)

\*1 When "1: Even number of bytes" or "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), the setting range of (s3)+0 (Number of request write data) is 1 to 32767.

\*2 Even when "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), specify the number in units of words. Add one byte to the odd number of bytes to be written and set the number in (s3)+0 (Number of request write data).

## Processing details

- This instruction writes the specified number of data to the specified file. Set the execution/completion type in the control data to specify the file write-target format.
- The write target is the SD memory card only.
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FWRITE instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan.
- If the SP.FWRITE instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- SM753 (File being accessed) turns on while the SP.FWRITE instruction is being executed.
- While SM753 is on, the SP.FWRITE instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- Even if an error is detected during the execution of the instruction, the bit devices (d2) and (d2)+1 and SM753 do not turn on.
- Specify data in (s3)+0, (d1)+4, (d1)+5, and (d1)+2 depending on the combination of (d1)+0 and (d1)+7.

\*3 The set value is from 00000000H to FFFFFFFEH (from the beginning of the file) or FFFFFFFFH (added to the end of the file).

## ■Writing binary data

- If the extension of the target file is omitted, the extension will be ".BIN".
- If a file that does not exist is specified, it will be created and data will be saved to the beginning of the file. The newly created file has the archive attribute.
- When an existing file is specified, data will be saved to the beginning of the file. If the size of data exceeds the size of the existing area in the file during writing, the excess data is additionally stored.
- If the specified position exceeds the existing file size, 0 point of data is written and the processing completes successfully.
- If the media runs out of free space during additional saving of data, an error occurs. In this case, the data already added and saved successfully is held as is and as much remaining data as possible is added and saved before termination with an error.
- In 16-bit binary data write mode, when the number of request write data and file position are specified, data is written as follows.

■Converting and writing data in CSV format

- If the extension is omitted, the extension will be ".CSV".
- When an existing file is specified, the following occurs.
  - When a value specified by (d1)+4 and (d1)+5 is other than FFFFFFFFH, data is saved to the file after deleting all the existing data in the file.
  - When a value specified by (d1)+4 and (d1)+5 is FFFFFFFFH, data is added and saved to the end of the file. If 1 is specified in (d1)+3, the return code at the end of the file will be converted to a comma and the data will be saved. However, if the end of the file is something other than a return code, the data will be saved from the end of the file without conversion to a comma.
- If a file that does not exist is specified, it will be created and data will be saved to the beginning of the file. The newly created file has the archive attribute.
- If the media runs out of free space during additional saving of data, an error occurs. In this case, the data already added and saved successfully is held as is and as much remaining data as possible is added and saved before termination with an error.
- When the number of columns is set to 0, data is read as a single-row data in a CSV format file.

Ex.

The number of columns is set to 0 when writing data after conversion to the CSV format.

(1) Specified in units of words  
(2) Same as the number of write data if case of normal completion

- When the specified number of columns is set to a value other than 0, a CSV format file is stored as the table with the specified number of columns.

**Ex.**

The number of columns is set to a value other than 0 when writing data after conversion to the CSV format.

(1) Specified in units of words

(2) Same as the number of write data if case of normal completion

- The following figure shows how data is added.

[Specify the file to which data will be written.] (Even if the file exists, it is deleted and re-created.)

- Execution/completion type: Writing data after converted to CSV format (Decimal (signed 16-bit data))
- File position: 00000000H (from the beginning of the file)
- Number of columns specification: 4H
- Data type specification: Words
- Write start device: D0
- Number of request write data: 6H

- (1) Starting row  
 (2) Data in the device (write data)  
 N: Number of data

[Added to the end of the file]

- Execution/completion type: Writing data after converted to CSV format (Decimal (signed 16-bit data))
- Application setting area: 0H
- File position: FFFFFFFFH (added to the end of the file)
- Number of columns specification: 3H
- Data type specification: Words
- Write start device: D7
- Number of request write data: 8H

**Point**

- An integral multiple of "Number of columns" should be specified for "Number of request write data". Otherwise, numbers of columns will be apart.
- The last data is always followed by a return code, so if the application setting area is 0, data is added starting from the beginning of a new line.
- When data is added to the end of a file, columns are shifted if "Number of columns" is changed from the previous writing.

[Added from the last line of the file]

- Execution/completion type: Writing data after converted to CSV format (Decimal (signed 16-bit data))
- Application setting area: 1H
- File position: FFFFFFFFH (added to the end of the file)
- Data type specification: Words
- Write start device: D7
- Number of request write data: 2H

(1) Starting position  
(2) Data in the device (write data)  
N: Number of data

\*1 If 1 is set in the application setting area, the return code at the end of the file will be converted to a comma, and data can be added from the last line.

- The following figures show an example of specifying "String (ASCII data)" for the execution/completion type.

**Ex.**

Writing data after converted to CSV format (string (ASCII data))

[Data to be written to a file]

- (1) Data to be written  
(2) File name  
(3) Control data

[Control data]

|     |       |
|-----|-------|
| D10 | H0130 |
| D11 | H0000 |
| D12 | -     |
| D13 | -     |
| D14 | K0    |
| D15 | K0    |
| D16 | K0    |
| D17 | K2    |

- D10: Execution/completion type: String (ASCII data)  
D11: Completion status  
D12: Number of data actually written  
D13: (Not used)  
D14, D15: File position  
D16: Number of columns  
D17: Data type specification

- D99: Number of request write data  
D100 to D102: String to be written to the 1st column of the 1st line  
D103, D104: String to be written to the 2nd column of the 1st line  
D105, D106: String to be written to the 3rd column of the 1st line

|   | A    | B   | C   | D |
|---|------|-----|-----|---|
| 1 | ABCD | 123 | 456 |   |
| 2 |      |     |     |   |

**Point**

- Set 00H (NULL) in the end of the string in an element. When the number of bytes of the string is even, set 0000H (two bytes of NULL) in the next one word.
- The maximum number of characters in one element is 1999. If this maximum number is exceeded and 00H (NULL) is not stored, characters of 2000th character and after are not written and the write processing shifts to the next element.
- A maximum of 1023 elements can be written in a single instruction execution.

- The following table lists values to set in (s3)+1 and later and data to be written in a CSV file when "0140H: Floating point real number (single-precision real number)" or "0141H: Floating point real number (double-precision real number)" is set to (d1)+0.

| Execution/completion type ((d1)+0)                               | Value to set in the write data ((s3)+1 and later)                                                                        | Data to be written in a CSV file                                                                    |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| 0140H: Floating point real number (single-precision real number) | Values within the range of: $-2^{128} < \text{data} \leq -2^{-126}$ ,<br>0,<br>$2^{-126} \leq \text{data} < 2^{128}$     | A value (0 to 7 digits in the decimal part) as given on the left is written in exponential format.  |
|                                                                  | Values other than above                                                                                                  | 0 is written. (Data cannot be converted.)                                                           |
| 0141H: Floating point real number (double-precision real number) | Values within the range of: $-2^{1024} < \text{data} \leq -2^{-1022}$ ,<br>0,<br>$2^{-1022} \leq \text{data} < 2^{1024}$ | A value (0 to 15 digits in the decimal part) as given on the left is written in exponential format. |
|                                                                  | Values other than above                                                                                                  | 0 is written. (Data cannot be converted.)                                                           |

- The following shows how the file size (total number of bytes) is calculated when a CSV format file is written to the SD memory card.

[Total number of bytes] = [Total number of bytes excluding the last row] + [Number of bytes of the last row]

([Number of bytes of each row] = [Number of columns<sup>\*2</sup>] + 1 + [total number of bytes of all data values per line]<sup>\*3</sup>)

- \*2 The specified number of columns applies to rows other than the last row. The number of columns of the last row is calculated as shown below because it may differ from the specified number of rows depending on the number of write data.

- The number of rows excluding the last row is calculated. (Number of rows excluding the last row = number of requested write data - number of columns (remainders rounded down))
- The number of columns of the last row is calculated. (Number of columns of the last row = number of requested write data - (number of rows excluding the last row × number of columns))

- \*3 The following shows how the number of bytes of each data value is calculated.

| Sign of data value | Number of bytes of each data value | Range of bytes                                             | Example                             |
|--------------------|------------------------------------|------------------------------------------------------------|-------------------------------------|
| Positive           | Number of digits                   | 1 to 5 (word specification)<br>1 to 3 (byte specification) | • 12345: 5 bytes<br>• 67: 2 bytes   |
| Negative           | Number of digits + 1               | 2 to 6 (word specification)<br>2 to 4 (byte specification) | • -12345: 6 bytes<br>• -67: 3 bytes |

## Precautions

- Do not execute the SP.FWRITE instruction in interrupt programs. Doing so may cause malfunction of the module.
- Since the SP.FWRITE instruction causes file write, the scan time may be extended when this instruction is executed.
- The SP.FWRITE instruction does not support character codes with BOM. To write to a CSV file with BOM that was created using Excel, use an application such as a text editor to change the character code to exclude BOM.

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

If the SP.FWRITE instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 663 Error codes generated for file operation instructions

# Deleting the specified file

## SP.FDELETE

This instruction deletes the specified file or folder in an SD memory card.

| Ladder | ST                                 |
|--------|------------------------------------|
|        | ENO:=SP_FDELETE(EN,U,s1,s2,d1,d2); |

## FBD/LD

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| SP.FDELETE  |                     |

## Setting data

## Descriptions, ranges, and data types

| Operand | Description                                                | Range                      | Data type      | Data type (label)                       |
|---------|------------------------------------------------------------|----------------------------|----------------|-----------------------------------------|

## Processing details

- This instruction deletes the file or folder specified by (s2) in the drive specified by (s1).
- SM753 (File being accessed) turns on while the SP.FDELETE instruction is being executed. While SM753 is on, the SP.FDELETE instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FDELETE instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan.
- If the SP.FDELETE instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

## Precautions

- Do not execute the SP.FDELETE instruction in interrupt programs. Doing so may cause malfunction of the module.
- Even though the operating status of the controller is switched from RUN to STOP during instruction execution, the controller continues the processing of the instruction.
- If the instruction is completed with an error during processing, the file or folder already deleted is not restored.
- When the size of a file to be deleted or the number of files to be deleted becomes larger, the instruction will take more time to complete.
- Do not access the file being processed by the SP.FDELETE instruction from other functions. (The file may be corrupt or an error may occur.)
- Do not operate files or folders being accessed from other functions.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

If the SP.FDELETE instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 663 Error codes generated for file operation instructions

## Copying the specified file

### SP.FCOPY

This instruction copies the specified file or folder in an SD memory card. When a folder is specified, the specified folder is copied in its entirety, or all the files and subfolders in the specified folder are copied.

| Ladder | ST                                     |

When it is omitted, (1) is up to 243 characters.<br/> (4) Can be omitted.</p> | Unicode string | User   |

## Processing details

- This instruction copies the file or folder specified by (s2) in the drive specified by (s1) to the folder specified by (s4) in the drive specified by (s3). When a folder is specified by (s2), a file and subfolder with the same names may exist in the copy destination. In this case, the instruction is not completed with an error even if the value of bit 1 (overwrite setting) of (d1) is 0. (Copying is skipped.)
- If the folder specified by (s4) does not exist in the copy destination, the folder is created automatically.
- SM753 (File being accessed) turns on while the SP.FCOPY instruction is being executed. While SM753 is on, the SP.FCOPY instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FCOPY instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan.
- If the SP.FCOPY instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

## Precautions

- Do not execute the SP.FCOPY instruction in an interrupt program. Doing so may cause malfunction of the module.
- Even though the operating status of the controller is switched from RUN to STOP during instruction execution, the controller continues the processing of the instruction.
- Ensure that the number of characters in a folder path or in the total of a folder path and a file name after copying does not exceed its limit. (The file may be inaccessible or an error may occur.)
- If the instruction is completed with an error during processing, the file or folder may remain under processing.
- When the size of a file to be copied or the number of files to be copied becomes larger, the instruction will take more time to complete.
- Do not access the file being processed by the SP.FCOPY instruction from other functions. (The file may be corrupt or an error may occur.)
- Do not operate files or folders being accessed from other functions.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

If the SP.FCOPY instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 663 Error codes generated for file operation instructions

## Moving the specified file

### SP.FMOVE

This instruction moves the specified file or folder in an SD memory card. When a folder is specified, the specified folder is moved in its entirety, or all the files and subfolders in the specified folder are moved.

## Processing details

- This instruction moves the file or folder specified by (s2) in the drive specified by (s1) to the folder specified by (s4) in the drive specified by (s3). If the folder specified by (s4) does not exist in the destination, the folder is created automatically.
- SM753 (File being accessed) turns on while the SP.FMOVE instruction is being executed. While SM753 is on, the SP.FMOVE instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FMOVE instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan.
- If the SP.FMOVE instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

## Precautions

- Do not execute the SP.FMOVE instruction in an interrupt program. Doing so may cause malfunction of the module.
- Even though the operating status of the controller is switched from RUN to STOP during instruction execution, the controller continues the processing of the instruction.
- Ensure that the number of characters in a folder path or in the total of a folder path and a file name after moving does not exceed its limit. (The file may be corrupt or an error may occur.)
- If overwriting occurs, the time to complete the instruction may be extended.
- When overwriting occurs, ensure a free space of the same size as the operation target file.
- If the instruction is completed with an error during processing, the file or folder may remain under processing.
- If the size of a file to be moved or the number of files to be moved becomes larger due to overwriting, the instruction will take more time to complete.
- Do not access the file being processed by the SP.FMOVE instruction from other functions. (The file may be inaccessible or an error may occur.)
- Do not operate files or folders being accessed from other functions.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

If the SP.FMOVE instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 663 Error codes generated for file operation instructions

# Renaming the specified file

## SP.FRENAME

This instruction renames the specified file or folder in an SD memory card.

| Ladder | ST                                               |

| +0 to +□      | File name/folder name | Specify the string of the file name/folder name after the change. <ul style="list-style-type: none"> <li>Do not specify a folder path.</li> <li>The file name (including the period and extension) must be within 64 characters.</li> <li>The folder name must be within 243 characters.</li> <li>Specify one character or more for the file name or folder name.</li> <li>Do not specify a delimiter.</li> <li>Do not put a period (one-byte) at the end of a string.</li> </ul> | Unicode string | User   |

### Processing details

- This instruction rename the file or folder specified by (s2) in the drive specified by (s1) to the file name or folder name specified by (s3). If the file name or folder name specified by (s3) already exists, the instruction is completed with an error.
- SM753 (File being accessed) turns on while the SP.FRENAME instruction is being executed. While SM753 is on, the SP.FRENAME instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d2) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FRENAME instruction is detected. The bit device (d2) turns off at the execution of the END instruction in the next scan.
- If the SP.FRENAME instruction completes with an error, the error completion device (d2)+1 turns on or off in synchronization with (d2).
- If an operation error is detected during the execution of the instruction, (d2) and (d2)+1 do not turn on.

### Precautions

- Do not execute the SP.FRENAME instruction in an interrupt program. Doing so may cause malfunction of the module.
- Even though the operating status of the controller is switched from RUN to STOP during instruction execution, the controller continues the processing of the instruction.
- Ensure that the number of characters in a folder path or in the total of a folder path and a file name after changing does not exceed its limit. (The file may be inaccessible or an error may occur.)
- Do not access the file being processed by the SP.FRENAME instruction from other functions. (The file may be corrupt or an error may occur.)
- Do not operate files or folders being accessed from other functions.

### Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

If the SP.FRENAME instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

📖 Page 663 Error codes generated for file operation instructions

# Acquiring the status of the specified file

## SP.FSTATUS

This instruction acquires the status of the specified file or folder in an SD memory card.

| Ladder | ST                                    |
|--------|---------------------------------------|
|        | ENO:=SP_FSTATUS(EN,U,s1,s2,d1,d2,d3); |

## FBD/LD

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| SP.FSTATUS  |                     |

## Setting data

## Descriptions, ranges, and data types

\*1 For files/folders accessed in an environment (OS) other than the controller, the range of values to be acquired depends on the environment (OS).

### Processing details

- This function acquires the status of the file or folder specified by (s2) in the drive specified by (s1) and stores it in the device (d2) and after. When a folder is specified by (s2), 0 is stored in (d2)+2 to (d2)+3.
- SM753 (File being accessed) turns on while the SP.FSTATUS instruction is being executed. While SM753 is on, the SP.FSTATUS instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- The processing completion bit device (d3) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FSTATUS instruction is detected. The bit device (d3) turns off at the execution of the END instruction in the next scan.
- If the SP.FSTATUS instruction completes with an error, the error completion device (d3)+1 turns on or off in synchronization with (d3).
- If an operation error is detected during the execution of the instruction, the processing completion (d3) and the error completion ((d3)+1) do not turn on.

### Precautions

- Do not execute the SP.FSTATUS instruction in an interrupt program. Doing so may cause malfunction of the module.
- Even though the operating status of the controller is switched from RUN to STOP during instruction execution, the controller continues the processing of the instruction.

### Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3285H            | <p>The drive specified by (s1) is not the one for the SD memory card.</p> <p>The file name/folder name string specified by (s2) cannot be read.</p> <ul style="list-style-type: none"> <li>• The specified file name string contains no character.</li> <li>• The specified file name string contains 254 characters or more.</li> <li>• The specified folder path contains 245 characters or more.</li> <li>• The specified folder path hierarchies contains 11 levels or more.</li> <li>• When a file is specified, the file name string ends with a delimiter.</li> <li>• The specified file name string has a period (one-byte) at its end or directly before each delimiter.</li> </ul> |

If the SP.FSTATUS instruction completes with an error, an error code is stored in the device specified by (d1)+1. (Note that an error code is not stored if the instruction results in an operation error.)

For the error code stored in (d1)+1, refer to the following.

 Page 663 Error codes generated for file operation instructions

## Error codes generated for file operation instructions

The following table lists the error codes that could be stored in the completion status of file operation instructions.

| Error code | Description                                                                                                                                                                                                                                    | Action                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8000H      | SM606 (SD memory card forced disable instruction) is on.                                                                                                                                                                                       | Turn off SM606 to cancel the SD memory card forced disable status.                                                                                                                                                                                                                                                                                                                                                                        |
|            | No SD memory card is inserted.                                                                                                                                                                                                                 | Insert an SD memory card.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|            | The SD memory card is not mounted.                                                                                                                                                                                                             | Mount the SD memory card.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 8001H      | An access to the SD memory card has failed.                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• Check that the file name string are correctly specified.</li> <li>• Check that no other functions are accessing the file.</li> <li>• Take measures to reduce noise.</li> <li>• Reset the controller and RUN it again. If the same error code is displayed again, the possible cause is a hardware failure of the SD memory card. Please contact your local Mitsubishi representative.</li> </ul> |
|            | The SD memory card is write-protected.                                                                                                                                                                                                         | Unlock the write protect switch of the SD memory card.                                                                                                                                                                                                                                                                                                                                                                                    |
|            | The file is set for read only.                                                                                                                                                                                                                 | Clear the read-only setting.                                                                                                                                                                                                                                                                                                                                                                                                              |
|            | The size of the file to be stored in the SD memory card exceeds the free space or the maximum capacity of the SD memory card.                                                                                                                  | <ul style="list-style-type: none"> <li>• Delete unnecessary files in the SD memory card to secure free space.</li> <li>• Adjust the file size so that it is equal to or less than its limit.</li> </ul>                                                                                                                                                                                                                                   |
|            |                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 8002H      | The specified file or folder does not exist.                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>• Check that the specified file or folder exists.</li> <li>• Check that the specified folder path exists.</li> </ul>                                                                                                                                                                                                                                                                               |
|            | The free space in the SD memory card is insufficient.                                                                                                                                                                                          | Delete unnecessary files in the SD memory card to secure free space.                                                                                                                                                                                                                                                                                                                                                                      |
| 8003H      | The total number of data read from the file has exceeded (d1)+3 (Maximum number of read data).                                                                                                                                                 | Adjust (d1)+2 (Number of read-target data) or (d1)+3 (Maximum number of read data).                                                                                                                                                                                                                                                                                                                                                       |

# 14.5 Data Control Instructions

## Upper and lower limit control of 16-bit binary data

### LIMIT(P)(\_U)

These instructions control the output value depending on whether the specified 16-bit binary bit value is within the upper and lower limits.

| Ladder | ST*1                        |                               |
|--------|-----------------------------|-------------------------------|
|        | ENO:=LIMITP(EN,s1,s2,s3,d); | ENO:=LIMITP_U(EN,s1,s2,s3,d); |

| FBD/LD*1 |
|----------|
|          |

\*1 The LIMIT and LIMIT\_U instructions do not support the ST and FBD/LD. Use the standard function, LIMIT.

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking the input value (16-bit binary data) in the device specified by (s3) with the upper and lower limit values specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                          | Output value           |
|--------------------------------------------------------------------|------------------------|
| Lower limit value (s1) > Input value (s3)                          | Lower limit value (s1) |
| Upper limit value (s2) < Input value (s3)                          | Upper limit value (s2) |
| Lower limit value (s1) ≤ Input value (s3) ≤ Upper limit value (s2) | Input value (s3)       |

- To control the input value only with the upper limit, set the minimum value within the setting range in (s1).
- To control the input value only with the lower limit, set the maximum value within the setting range in (s2).

## Operation error

| Error code (SD0) | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| 3285H            | The lower limit value specified by (s1) is greater than the upper limit value specified by (s2). |

# Upper and lower limit control of 32-bit binary data

## DLIMIT(P)(\_U)

These instructions control the output value depending on whether the specified 32-bit binary bit value is within the upper and lower limits.

| Ladder | ST <sup>*1</sup>             |                                |
|--------|------------------------------|--------------------------------|
|        | ENO:=DLIMITP(EN,s1,s2,s3,d); | ENO:=DLIMITP_U(EN,s1,s2,s3,d); |

## FBD/LD<sup>\*1</sup>

<sup>\*1</sup> The DLIMIT and DLIMIT\_U instructions do not support the ST and FBD/LD. Use the standard function, LIMIT.

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking the input value (32-bit binary data) in the device specified by (s3) with the upper and lower limit values specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                                                        | Output value                     |
|--------------------------------------------------------------------------------------------------|----------------------------------|
| Lower limit value ((s1), (s1)+1) > Input value ((s3), (s3)+1)                                    | Lower limit value ((s1), (s1)+1) |
| Lower limit value ((s2), (s2)+1) < Input value ((s3), (s3)+1)                                    | Upper limit value ((s2), (s2)+1) |
| Lower limit value ((s1), (s1)+1) ≤ Input value ((s3), (s3)+1) ≤ Upper limit value ((s2), (s2)+1) | Input value ((s3), (s3)+1)       |

- To control the input value only with the upper limit, set the minimum value within the setting range in (s1).
- To control the input value only with the lower limit, set the maximum value within the setting range in (s2).

## Operation error

| Error code (SD0) | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| 3285H            | The lower limit value specified by (s1) is greater than the upper limit value specified by (s2). |

# Dead band control of 16-bit binary data

## BAND(P)(\_U)

These instructions control the output value depending on whether the specified 16-bit binary bit value is within the upper and lower limits of the dead band.

## Processing details

- These instructions control the output value to be stored in the device specified by (d) by checking whether the input value (16-bit binary data) in the device specified by (s3) is within range of the upper and lower limits of the dead band in the devices specified by (s1) and (s2). The output value is controlled as follows.

| Condition                                                                        | Output value                                        |
|----------------------------------------------------------------------------------|-----------------------------------------------------|
| Dead band lower limit value (s1) > input value (s3)                              | Input value (s3) - dead band lower limit value (s1) |
| Dead band upper limit value (s2) < input value (s3)                              | Input value (s3) - dead band upper limit value (s2) |
| Dead band lower limit value (s1) ≤ input value (s3) ≤ dead band upper limit (s2) | 0                                                   |

- The following example shows the case where the operation result of the BAND(P) instruction is out of the range from -32768 to 32767.

**Ex.**

When (s1) is 10 and (s3) is -32768, output value is  $-32768 - 10 = 8000\text{H} - 000\text{AH} = 7\text{FF}6\text{H} = 32758$ .

- The following example shows the case when the operation result of the BAND(P)\_U instruction is out of the range from 0 to 65535.

**Ex.**

When (s1) is 100 and (s3) is 50, output value is  $50 - 100 = 0032\text{H} - 0064\text{H} = \text{FFCEH} = 65486$ .

## Processing details

- These instructions add the bias value specified by (s1) or (s2) to the input value (16-bit binary) specified by (s3), and store the result in the device number specified by (d). The bias value is controlled as follows.

| Condition            | Output value                                |
|----------------------|---------------------------------------------|
| Input value (s3) < 0 | Input value (s3) + negative bias value (s1) |
| Input value (s3) < 0 | 0                                           |
| Input value (s3) < 0 | Input value (s3) + positive bias value (s2) |

- The following example shows the case where the operation result of the ZONE(P) instruction is out of the range from -32768 to 32767.

**Ex.**

When (s1) is -100 and (s3) is -32768, output value is  $-32768 + (-100) = 8000\text{H} - \text{FF}9\text{CH} = 7\text{F}9\text{CH} = 32668$ .

- The following example shows the case where the operation result of the ZONE(P)\_U instruction is out of the range from 0 to 65535.

**Ex.**

When (s2) is 100 and (s3) is 65535, output value is  $65535 + 100 = \text{FFFFH} - 0064\text{H} = 0063\text{H} = 99$ .

- The ZONE(P)\_U instruction treats the data in the device specified by (s1) as dummy and does not use it.

## Operation error

There is no operation error.

# Zone control of 32-bit binary data

## DZONE(P)(\_U)

These instructions add a bias value to the specified input value (32-bit binary).

## Processing details

- These instructions scale the scaling conversion data (16-bit data) in the device specified by (s2) on the basis of the input value in the device specified by (s1), and stores the operation result in the device specified by (d). Scaling conversion is performed based on the scaling conversion data stored in the device specified by (s2) and later.

| Setting item (n is the number of coordinate points specified by (s2).) |              | Device assignment |
|------------------------------------------------------------------------|--------------|-------------------|
| Number of coordinate points                                            |              | (s2)              |
| Point 1                                                                | X coordinate | (s2)+1            |
|                                                                        | Y coordinate | (s2)+2            |
| Point 2                                                                | X coordinate | (s2)+3            |
|                                                                        | Y coordinate | (s2)+4            |
| ⋮                                                                      |              |                   |
| Point n                                                                | X coordinate | (s2)+2n-1         |
|                                                                        | Y coordinate | (s2)+2n           |

- If the operation result is not an integer, the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in ascending order.
- Set the value in (s1) within the range of the scaling conversion data (device value in (s2)).
- If two or more points indicate the same X coordinate, the Y coordinate value of the largest point number is output.
- Specify a value from 1 to 65535 for the number of coordinate points of the scaling conversion data specified by (s2).

## Precautions

- The search method and the number of searches vary depending on whether SM755 is on or off.

| SM755 | Search method     | Number of searches                            |
|-------|-------------------|-----------------------------------------------|
| Off   | Sequential search | $1 \leq \text{number of searches} \leq 65535$ |
| On    | Binary search     | $1 \leq \text{number of searches} \leq 16$    |

- When the scaling conversion data is sorted in ascending order, the search method varies depending on the status of SM755 and therefore the processing speed also varies. The processing speed depends on the number of searches and is faster as the number of searches is less.

- Case in which the processing speed of sequential search is faster

When the coordinate point specified by (s1) is one from 1 to 15 while the number of coordinate points is the maximum, the number of sequential searches is equal to or less than 15 and therefore the processing speed of the sequential search becomes faster.

- Case in which the processing speed of binary search is faster

The maximum number of searches is 16 and therefore when coordinate point 17 or later is specified by (s1), the number of binary searches is equal to or less than the number of sequential searches, and accordingly the processing speed of the binary search becomes faster.

- (1) The processing speed of the sequential search is faster because the number of sequential searches is less than the number of binary searches.  
 (2) The processing speed of the binary search is faster because the number of binary searches is less than the number of sequential searches.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                           |

## Processing details

- These instructions scale the scaling conversion data (32-bit data) in the device specified by (s2) on the basis of the input value in the device specified by (s1), and stores the operation result in the device specified by (d). Scaling conversion is performed based on the scaling conversion data stored in the device specified by (s2) and later.

| Setting item (n is the number of coordinate points specified by (s2).) |              | Device assignment    |
|------------------------------------------------------------------------|--------------|----------------------|
| Number of coordinate points                                            |              | (s2)+1, (s2)         |
| Point 1                                                                | X coordinate | (s2)+3, (s2)+2       |
|                                                                        | Y coordinate | (s2)+5, (s2)+4       |
| Point 2                                                                | X coordinate | (s2)+7, (s2)+6       |
|                                                                        | Y coordinate | (s2)+9, (s2)+8       |
| ⋮                                                                      |              |                      |
| Point n                                                                | X coordinate | (s2)+4n-1, (s2)+4n-2 |
|                                                                        | Y coordinate | (s2)+4n+1, (s2)+4n   |

- If the operation result is not an integer, the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in ascending order.
- Set the value in (s1) within the range of the scaling conversion data (device value in (s2), (s2)+1).
- If two or more points indicate the same X coordinate, the Y coordinate value of the largest point number is output.
- Specify a value from 1 to 4294967295 for the number of coordinate points of the scaling conversion data specified by (s2).

## Precautions

- The search method and the number of searches vary depending on whether SM755 is on or off.

| SM755 | Search method     | Number of searches                                 |
|-------|-------------------|----------------------------------------------------|
| Off   | Sequential search | $1 \leq \text{number of searches} \leq 4294967295$ |
| On    | Binary search     | $1 \leq \text{number of searches} \leq 32$         |

- When the scaling conversion data is sorted in ascending order, the search method varies depending on the status of SM755 and therefore the processing speed also varies. The processing speed depends on the number of searches and is faster as the number of searches is less.

- Case in which the processing speed of sequential search is faster

When the coordinate point specified by (s1) is one from 1 to 15 while the number of coordinate points is the maximum, the number of sequential searches is equal to or less than 15 and therefore the processing speed of the sequential search becomes faster.

- Case in which the processing speed of binary search is faster

The maximum number of searches is 32 and therefore when coordinate point 33 or later is specified by (s1), the number of binary searches is equal to or less than the number of sequential searches, and accordingly the processing speed of the binary search becomes faster.

- (1) The processing speed of the sequential search is faster because the number of sequential searches is less than the number of binary searches.  
 (2) The processing speed of the binary search is faster because the number of binary searches is less than the number of sequential searches.

## Operation error

| Y coordinate                                                           | Point 1 | (s2)+n+1          |
|                                                                        | Point 2 | (s2)+n+2          |
|                                                                        | ⋮       | ⋮                 |
|                                                                        | Point n | (s2)+2n           |

- If the operation result is not an integer, the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in ascending order.
- Set the value in (s1) within the range of the scaling conversion data (device value in (s2)).
- If two or more points indicate the same X coordinate, the Y coordinate value of the largest point number is output.
- Specify a value from 1 to 65535 for the number of coordinate points of the scaling conversion data.

## Precautions

When the scaling conversion data is sorted in ascending order, the search method varies depending on the status of SM755 and therefore the processing speed also varies. For details, refer to the SCL(P)(\_U) instruction.

📖 Page 676 SCL(P)(\_U)

## Operation error

## Processing details

- These instructions scale the scaling conversion data (32-bit data) in the device specified by (s2) on the basis of the input value in the device specified by (s1), and stores the operation result in the device specified by (d). Scaling conversion is performed based on the scaling conversion data stored in the device specified by (s2) and later.

| Setting item (n is the number of coordinate points specified by (s2).) |         | Device assignment    |
|------------------------------------------------------------------------|---------|----------------------|
| Number of coordinate points                                            |         | (s2)+1, (s2)         |
| X coordinate                                                           | Point 1 | (s2)+3, (s2)+2       |
|                                                                        | Point 2 | (s2)+5, (s2)+4       |
|                                                                        | ⋮       | ⋮                    |
|                                                                        | Point n | (s2)+2n+1, (s2)+2n   |
| Y coordinate                                                           | Point 1 | (s2)+2n+3, (s2)+2n+2 |
|                                                                        | Point 2 | (s2)+2n+5, (s2)+2n+4 |
|                                                                        | ⋮       | ⋮                    |
|                                                                        | Point n | (s2)+4n+1, (s2)+4n   |

- If the operation result is not an integer, the first decimal place is rounded off.
- Set the X coordinate data of the scaling conversion data in ascending order.
- Set the value in (s1) within the range of the scaling conversion data (device value in (s2) to (s2)+1).
- If two or more points indicate the same X coordinate, the Y coordinate value of the largest point number is output.
- Specify a value from 1 to 4294967295 for the number of coordinate points of the scaling conversion data.

## Precautions

When the scaling conversion data is sorted in ascending order, the search method varies depending on the status of SM755 and therefore the processing speed also varies. For details, refer to the DSCL(P)(U) instruction.

📖 Page 679 DSCL(P)(U)

## Operation error

## Processing details

- These instructions search the (n) points in units of 16-bit binary data from the device specified by (s2) using the 16-bit binary data in the device specified by (s1) as a keyword. Each instruction stores the number of data which matches the keyword in the device specified by (d)+1 and also stores the relative value of the first-matched device number from (s2) in the device specified by (d).

- If the value specified by (n) is 0, no processing is performed.
- If no matching data is found as the result of search, 0 is stored in the devices specified by (d) and (d)+1.

### Point

- If the data to be searched by the SERDATA(P) instruction has been sorted in ascending order, turning on SM702<sup>\*1</sup> enables a binary search which can process the search faster. If SM702 is turned on even though the data to be search has not been sorted in ascending order, normal search results cannot be obtained. The following figure shows an example of binary search.

<sup>\*1</sup> SM702 is a special relay for setting the search method.

SM702 is off: Sequential search (linear search)

This method compares the search data with the data to be searched for starting from the start of data

SM702 is on: Binary search

For the data that has been sorted in ascending order, this method checks the center value of the search range, determining whether the center value is larger or smaller than the search value, and thereby narrows the search range to either side. Thus, target data is searched for by repeating this processing.

## Operation error

There is no operation error.

# Searching 32-bit binary data

## DSERDATA(P)

These instructions search the (n) points in the 32-bit binary data specified by (s2) for the 32-bit binary data specified by (s1).

| Ladder | ST                                                                    |

## Processing details

- These instructions search the (n) points of data in units of 32-bit binary data ( $2 \times (n)$  points of data in units of 16 bits) from the device specified by (s2), using the 32-bit binary data in the device specified by (s1) as a keyword. Each instruction stores the number of data which matches the keyword in the device specified by (d)+1 and also stores the relative value of the first-matched device number from (s2) in the device specified by (d).

- If the value specified by (n) is 0, no processing is performed.
- If no matching data is found as the result of search, 0 is stored in the devices specified by (d) and (d)+1.

## Point

- If the data to be searched by the DSERDATA(P) instruction has been sorted in ascending order, turning on SM702<sup>\*1</sup> enables a binary search which can process the search faster. If SM702 is turned on even though the data to be search has not been sorted in ascending order, normal search results cannot be obtained. The following figure shows an example of binary search.

<sup>\*1</sup> SM702 is a special relay for setting the search method.

SM702 is off: Sequential search (linear search)

This method compares the search data with the data to be searched for starting from the start of data

SM702 is on: Binary search

For the data that has been sorted in ascending order, this method checks the center value of the search range, determining whether the center value is larger or smaller than the search value, and thereby narrows the search range to either side. Thus, target data is searched for by repeating this processing.

## Operation error

There is no operation error.

# Searching 16-bit binary data (minimum, match, maximum)

## SERMM(P)

These instructions search the (n) points in the 16-bit binary data specified by (s1) for the same data as the 16-bit binary data specified by (s2), the minimum value, and the maximum value.

## Processing details

- These instructions search the same data as the 16-bit binary data of (s2) in (n) data starting from (s1), and store the search result in (d) to (d)+4.
- When the same data exists, five devices starting from (d) store the number of the same data, first and last positions of the same data, maximum value position, and minimum value position.
- When the same data does not exist, five devices starting from (d) store the number of the same data, first and last positions of the same data, maximum value position, and minimum value position. In this case, however, 0s are stored in three devices starting from (d) (which store the number of the same data, first and last positions of the same data).
- When there are two or more maximum or minimum values in the searched data, the last position of the maximum/minimum values is stored.
- If the value specified by (n) is 0, no processing is performed.
- The following table shows example of configuration of search result table and data. (n=10)

| Searched device (s1) | Searched data (s1) value (example) | Comparison data (s2) value (example) | Data position | Search result       |                    |                     |

## Processing details

- These instructions search the same data as the 32-bit binary data of (s2)+1 and (s2) in (n) data starting from (s1)+1 and (s1), and store the search result in [(d)+1, (d)] to [(d)+9, (d)+8].
- When the same data exists, five devices starting from (d)+1 and (d) store the number of the same data, first and last positions of the same data, maximum value position, and minimum value position.
- When the same data does not exist, five devices starting from (d)+1 and (d) store the number of the same data, first and last positions of the same data, maximum value position and minimum value position. In this case, however, 0s are stored in three devices starting from (d)+1 and (d) (which store the number of the same data, first and last positions of the same data).
- When there are two or more maximum or minimum values in the searched data, the last position of the maximum/minimum values is stored.
- If the value specified by (n) is 0, no processing is performed.
- The following table shows example of configuration of search result table and data. (n=10)

| Searched device (s1) | Searched data (s1) value (example) | Comparison data (s2) value (example) | Data position | Search result              |                    |                            |

### Processing details

These instructions search the (n) points of 16-bit binary data in the device specified by (s) for the maximum value, and store the maximum value in the device specified by (d). Each instruction searches data starting from the device specified by (s) and detects first the maximum value in the xth point from (s), and stores x in (d)+1 and the number of maximum values in (d)+2.

### Operation error

There is no operation error.

# Searching the maximum value of 32-bit binary data

## DMAX(P)(\_U)

These instructions search the (n) points of 32-bit binary data in the specified device for the maximum value.

| Ladder | ST*1                  |                         |
|--------|-----------------------|-------------------------|
|        | ENO:=DMAXP(EN,s,n,d); | ENO:=DMAXP_U(EN,s,n,d); |

| FBD/LD*1 |
|----------|
|          |

\*1 The DMAX and DMAX\_U instructions do not support the ST and FBD/LD. Use the standard function, MAX.

☞ Page 1360 MAX(\_E), MIN(\_E)

## Execution condition

| Instruction      | Execution condition |
|------------------|---------------------|
| DMAX<br>DMAX_U   |                     |
| DMAXP<br>DMAXP_U |                     |

## Setting data

## Description, range, data type

| Operand | Description           | Range      | Data type              | Data type (label)   |
|---------|-----------------------|------------|------------------------|---------------------|
| (s)     | DMAX(P)               | —          | 32-bit signed binary   | ANY32_S*1           |
|         | DMAX(P)_U             |            | 32-bit unsigned binary | ANY32_U*1           |
| (d)     | DMAX(P)               | —          | 32-bit signed binary   | —*2 (ANY32_S_ARRAY) |
|         | DMAX(P)_U             |            | 32-bit unsigned binary | —*2 (ANY32_U_ARRAY) |
| (n)     | Number of search data | 0 to 65535 | 16-bit unsigned binary | ANY16               |
| EN      | Execution condition   | —          | Bit                    | BOOL                |
| ENO     | Execution result      | —          | Bit                    | BOOL                |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

\*2 Specify a device regardless of the programming language used. Do not specify labels.

## Applicable devices

\*1 T, C, and ST cannot be used.

## Processing details

- These instructions sort (n) points of 16-bit binary data from (s1) in ascending or descending order. Data is sorted in ascending order when SM703 is off and in descending order when SM703 is on.

(1) Data are sorted in descending order.

(2) Data are sorted in ascending order.

- Sorting by the SORTD(\_U) instruction requires several scans. The number of scans required till completion of sorting is determined by dividing the maximum number of executions performed before completion of sorting by the number of data compared once specified by (s2). (The decimal fractions are rounded up.) When the value in (s2) is increased, the number of scans before completion of sorting is decreased but the scan time is increased.
- The maximum number of executions before completion of sorting is calculated by  $(n) \times (n-1) \div 2$  (times). When (n)=10, for example,  $10 \times (10-1) \div 2 = 45$  times. At this time, setting (s2)=2, for example, makes  $45 \div 2 = 22.5$  meaning that 23 scans are required before completion of sorting.
- The completion device specified by (d1) turns off at start of execution of the SORTD(\_U) instruction and turns on upon completion of sorting. After completion of sorting, the device specified by (d1) is kept on. Turn it off as needed.
- The two points from the device specified by (d2) are used by the system at execution of the SORTD(\_U) instruction. Do not change the two points from the device specified by (d2). If they are changed, an error may occur. (Error code: 3285H)
- If the value in (n) is changed during sorting, the new number of sort data is used for sorting.
- If the execution command is turned off during sorting, sorting is interrupted. If the execution command is turned on again, sorting is performed from the beginning.
- If the next sorting is performed continuously after completion of the previous sorting, the execution command needs to be turned off and turned on again.

## Operation error

\*1 FX and FY cannot be used.

## Processing details

These instructions perform a square root operation of the 32-bit binary data specified by (s). and stores the result in (d). The obtained square root is an integer because the decimal places are rounded down.

$$\sqrt{(s)+1}, (\overline{s}) \rightarrow (d)$$

## Operation error

There is no operation error.

# CRC operation

## CRC(P)

These instructions generate the CRC value for (n) 8-bit data (unit: byte) starting from the device specified by (s), and store the CRC value to the device specified by (d).

| Ladder | ST                                          |
|--------|---------------------------------------------|
|        | ENO:=CRC(EN,s,n,d);<br>ENO:=CRCP(EN,s,n,d); |

| FBD/LD |
|--------|
|        |

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| CRC         |                     |
| CRCP        |                     |

## Setting data

### Description, range, data type

| Operand | Description                                                                                                                        | Range      | Data type              | Data type (label) |
|---------|------------------------------------------------------------------------------------------------------------------------------------|------------|------------------------|-------------------|
| (s)     | Start device where the target data of CRC value generation is stored                                                               | —          | 16-bit signed binary   | ANY16             |
| (d)     | Device where the generated CRC value is stored                                                                                     | —          | 16-bit signed binary   | ANY16             |

\*1 FX and FY cannot be used.

## Processing details

- These instructions generate the CRC value for (n) 8-bit data (unit: byte) starting from the device specified by (s), and store the CRC value to the device specified by (d). " $X^{16} + X^{15} + X^2 + 1$ " is used in the generator polynomial of the CRC value (CRC-16). The 16-bit conversion mode and 8-bit conversion mode are available for these instructions. The conversion mode can be selected by turning on or off SM772.
- If the value specified by (n) is 0, no processing is performed.
- The operation in each conversion mode is described below.

### ■16-bit conversion mode (while SM772 is OFF)

In this mode, the CRC operation is executed for upper 8 bits (in units of byte) and lower 8 bits (in units of byte) of the device specified by (s). The operation result is stored to 16 bits in one device specified by (d).

#### Ex.

When (n)=6

In 16-bit conversion mode, the six bytes in the following shaded portion become an operation target. The CRC value is determined as "A57BH", and therefore "A57BH" is stored in the device specified by (d).

|    | Decimal | Hexadecimal |       |
|----|---------|-------------|-------|
|    |         | Upper       | Lower |
| D0 | 24932   | 61H         | 64H   |
| D1 | 4219    | 10H         | 7BH   |
| D2 | -1333   | FAH         | CBH   |
| D3 | -1      | FFH         | FFH   |
| D4 | 32761   | 7FH         | F9H   |
| D5 | 10000   | 27H         | 10H   |

### ■8-bit conversion mode (while SM772 is ON)

CRC operation is executed only for lower 8 bits (lower byte) of the device specified by (s). With regard to the operation result, lower 8 bits (in units of byte) are stored to the device specified by (d), and upper 8 bits (in units of byte) are stored to a device specified by (d)+1.

#### Ex.

When (n)=6

In 8-bit conversion mode, the six bytes in the following shaded portion become an operation target. The CRC value is "BDA1H" and therefore "A1H" is stored in the device specified by (d) and "BDH" is stored in the device specified by (d)+1.

|    | Decimal | Hexadecimal |       |
|----|---------|-------------|-------|
|    |         | Upper       | Lower |
| D0 | 24932   | 61H         | 64H   |
| D1 | 4219    | 10H         | 7BH   |
| D2 | -1333   | FAH         | CBH   |
| D3 | -1      | FFH         | FFH   |
| D4 | 32761   | 7FH         | F9H   |
| D5 | 10000   | 27H         | 10H   |

## Operation error

| Error code (SD0) | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| 3285H            | A digit other than 4 is specified in the digit-specified bit device in (s) and (d). |

# 15 DEBUGGING AND FAILURE DIAGNOSTIC

## 15.1 Debugging and Failure Diagnostic Instructions

### Resetting the error display and the annunciator display

#### LEDR

This instruction resets the self-diagnostic error (continuation error) display and the annunciator display of the controller.

| Ladder | ST             |
|--------|----------------|
|        | ENO:=LEDR(EN); |

| FBD/LD |
|--------|
|        |

#### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| LEDR        |                     |

#### Processing details

- This instruction resets the self-diagnostic error (continuation error) display and the annunciator display of the controller.  
Executing the instruction once resets both the error display and the annunciator display.
- When a self-diagnostic error has occurred, the controller operates as follows:
  - When a self-diagnostic error (continuation error) has occurred  
The ERROR LED on the front of the controller remains off.  
The values in SM0, SM1, and SD0 are not reset automatically at this time. Reset the values by the program.
  - When a battery error has occurred  
When the LEDR instruction is executed after battery replacement, the BATTERY LED on the front of the controller turns off. At this time, SM51 also turns off.
- When the annunciator (F) is on, the controller operates as follows:
  - The USER LED turns off.
  - The values in SD62, SD63, and SD64 to SD79 are all cleared to 0.

| Before execution | After execution |
|------------------|-----------------|
| SD62 200         | SD62 0          |
| SD63 15          | SD63 0          |
| SD64 200         | SD64 0          |
| SD65 99          | SD65 0          |
| SD66 5           | SD66 0          |
| SD67 255         | SD67 0          |
| ⋮                | ⋮               |
| SD78 83          | SD78 0          |
| SD79 0           | SD79 0          |

(1)

(1) All data are cleared.

#### Operation error

There is no operation error.

# 16 STRING PROCESSING

## 16.1 String Processing Instructions

### Comparing string data

#### LD\$, AND\$, OR\$

These instructions compare string data as normally open contacts.

| Ladder                                                                            | ST                                                                                                                                                            |
|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | ENO:=LDSTRING_□(EN,s1,s2);<br>ENO:=ANDSTRING_□(EN,s1,s2);<br>ENO:=ORSTRING_□(EN,s1,s2);<br>(□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)*1 |
| (□ is replaced by \$=, \$<>, \$>, \$<=, \$<, or \$>=.)                            |                                                                                                                                                               |

| FBD/LD                                                                                                   |
|----------------------------------------------------------------------------------------------------------|
|                       |
| (□ is replaced by a combination of LDSTRING_, ANDSTRING_, or ORSTRING_ and EQ, NE, GT, LE, LT, or GE.)*1 |

\*1 EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

#### ■Execution condition

| Instruction       | Execution condition |
|-------------------|---------------------|
| LD\$, AND\$, OR\$ | Every scan          |

### Setting data

#### ■Description, range, data type

| Operand | Description                                                             | Range | Data type | Data type (label) |
|---------|-------------------------------------------------------------------------|-------|-----------|-------------------|
| (s1)    | Comparison data or the start device where the comparison data is stored | —     | String    | ANYSTRING_SINGLE  |

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s1)    | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | ○  | —      |
| (s2)    | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | ○  | —      |

## Processing details

- These instructions perform a comparison operation between the string data in the device specified by (s1) and the string data in the device specified by (s2). (Devices are used as normally open contacts).
- In comparison operation, the ASCII code of string is compared character by character from the beginning of the string.
- The strings in the devices specified by (s1) and (s2) mean those in the device numbers from the specified one to the one containing 00H.
- The comparison result turns out matching if all strings match.

| □ Instruction symbol (ladder, FBD/LD) | Result                             |
|---------------------------------------|------------------------------------|
| \$=, EQ                               | Continuity state (ENO is on.)      |
| \$<>, NE                              | Non-continuity state (ENO is off.) |
| \$>, GT                               | Non-continuity state (ENO is off.) |
| \$<=, LE                              | Continuity state (ENO is on.)      |
| \$<, LT                               | Non-continuity state (ENO is off.) |
| \$>=, GE                              | Continuity state (ENO is on.)      |

- When different strings are compared, the string with a larger character code is greater.

| □ Instruction symbol (ladder, FBD/LD) | Result                             |
|---------------------------------------|------------------------------------|
| \$=, EQ                               | Non-continuity state (ENO is off.) |
| \$<>, NE                              | Continuity state (ENO is on.)      |
| \$>, GT                               | Continuity state (ENO is on.)      |
| \$<=, LE                              | Non-continuity state (ENO is off.) |
| \$<, LT                               | Non-continuity state (ENO is off.) |
| \$>=, GE                              | Continuity state (ENO is on.)      |

- When different strings are compared, the relative size of a string is determined by the relative size of the first different character codes.

| □ Instruction symbol (ladder, FBD/LD) | Result                             |
|---------------------------------------|------------------------------------|
| \$=, EQ                               | Non-continuity state (ENO is off.) |
| \$<>, NE                              | Continuity state (ENO is on.)      |
| \$>, GT                               | Non-continuity state (ENO is off.) |
| \$<=, LE                              | Continuity state (ENO is on.)      |
| \$<, LT                               | Continuity state (ENO is on.)      |
| \$>=, GE                              | Non-continuity state (ENO is off.) |

- When the lengths of the string data in the devices specified by (s1) and (s2) are different, the longer string data is greater.

| □ Instruction symbol (ladder, FBD/LD) | Result                             |
|---------------------------------------|------------------------------------|
| \$=, EQ                               | Non-continuity state (ENO is off.) |
| \$<>, NE                              | Continuity state (ENO is on.)      |
| \$>, GT                               | Continuity state (ENO is on.)      |
| \$<=, LE                              | Non-continuity state (ENO is off.) |
| \$<, LT                               | Non-continuity state (ENO is off.) |
| \$>=, GE                              | Continuity state (ENO is on.)      |

- The string in the device specified by (s1) or (s2) exceeds 16383 characters, the operation result will be non-continuity (ENO OFF).
- If the LDSTRING\_□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the ORSTRING\_□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.

### Operation error

There is no operation error.

**Point**

The string comparison instructions perform the following checks while comparing strings.

- Checking whether the device area range is exceeded
- Checking whether the string is within 16383 characters

If 00H does not exist in the device area or the string exceeds 16383 characters and a character mismatch is detected, the instruction outputs comparison operation results without causing non-continuity (ENO OFF). The following example shows the operation result when the last device number of the device area is D12287.

(s1)      (s2)

(s1)

"ABCDEF"

↑ (1)

(s2)

b15...b8
b7...b0

"Z"
"A"

D12287

(2) →

Outside the device area

(1) The second character of (s1) differs from that of (s2) ((s1)≠(s2)), and accordingly the operation result will be continuity (ENO ON).

(2) D12287 and later are outside the device area, and accordingly string data comparison is performed using data up to D12287.

Since a string mismatch has been detected, the condition is satisfied and processing ends.

# Concatenating string data

## \$+(P) [when two operands are set]

These instructions concatenate string data.

| Ladder                                                                                                                                              | ST                                                                                                                                                  |

## Processing details

- These instructions transfer the string data in the device specified by (s) to the device number specified by (d) and later. The strings specified by (s) or the strings from the device number specified by (s) to the device number containing 00H are transferred all at once.

- Even when the device range ((s) to (s)+n) in which the string data to be transferred and the device range ((d) to (d)+n) for storing the transferred data are overlapping, the processing is performed normally. For example, the strings stored in the devices specified by D10 to D13 are transferred to the devices specified by D11 to D14 as shown below.

A: Data remain the same.

- When 00H is stored in the lower byte of (s)+n, 00H will be stored in both upper and lower bytes of (d)+n.

(1) Data (upper byte) is not transferred.

(2) Data remain the same.

(3) 00H is automatically stored in the upper byte.

## Operation error

| Error code (SD0) | Description                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (00H) in the assignment range of the relevant device/label for the device number specified by (s) and later.                           |
| 3285H            | The number of characters in the string specified by (s) exceeds 16383.                                                                                       |
| 3286H            | The entire string that was specified in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored. |

## Transferring Unicode string data

### \$MOV(P)\_WS

These instructions transfer Unicode string data to the specified device number and later.

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|

## Processing details

- These instructions transfer the Unicode string data in the device specified by (s) to the device number specified by (d) and later. The Unicode strings specified by (s) or the Unicode strings from the device number specified by (s) to the device number containing 0000H are transferred all at once.

- Even when the device range ((s) to (s)+n) in which the Unicode string data to be transferred and the device range ((d) to (d)+n) for storing the transferred data are overlapping, the processing is performed normally. For example, the strings stored in the devices specified by D10 to D13 are transferred to the devices specified by D11 to D14 as shown below.

A: Same as before transfer

## Operation error

| Error code (SD0) | Description                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (0000H) in the assignment range of the relevant device/label for the device number specified by (s) and later.                                 |
| 3285H            | The number of characters in the Unicode string specified by (s) exceeds 16383.                                                                                       |
| 3286H            | The entire Unicode string that was specified in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored. |

# Converting 16-bit binary data to decimal ASCII

16

## BINDA(P)(\_U)

These instructions convert 16-bit binary data to the decimal ASCII code.

| Ladder                                                                            | ST                                         |                                                |

## Processing details

- These instructions convert the digit in decimal notation of the 16-bit binary data in the device specified by (s) to the ASCII code, and store the converted data in the device number specified by (d) and later.
- The format of the decimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Storage format of (d)                                              | Reference                                                                       |
|-----------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Off             | Data is stored in a fixed number of digits (a sign + 5 digits)     | Page 735 Operation of when SM705 (Number of conversion digits selection) is off |
| On              | Each digit is stored left-justified depending on the value of (s). | Page 735 Operation of when SM705 (Number of conversion digits selection) is on  |

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the BINDA(P) instruction is executed with the numeric value "-12" stored in (s)

- When SM705 is off, the number of digits is fixed. The first character is a sign and it is 2DH(-) in the above example. (If (s) is 0 or positive, the first character is 20H (space).) The numeric part is right-justified. When the length of the numeric part is less than 5 digits, the ASCII code 20H (space) is stored for the ASCII code of the upper digit(s).
- When SM705 is on, data is left-justified. When the length of the numeric part is less than 5 digits, 00H is stored in the end.

## ■Operation of when SM705 (Number of conversion digits selection) is off

Decimal ASCII data is stored in a fixed number of digits in (d) to (d)+2.

ASCII S: Sign data of ASCII code<sup>\*1</sup>

ASCII 10<sup>4</sup>: Ten-thousands place of ASCII code<sup>\*2</sup>

ASCII 10<sup>3</sup>: Thousands place of ASCII code<sup>\*3</sup>

ASCII 10<sup>2</sup>: Hundreds place of ASCII code<sup>\*4</sup>

ASCII 10<sup>1</sup>: Tens place of ASCII code<sup>\*5</sup>

ASCII 10<sup>0</sup>: Ones place of ASCII code

(1) 00H is stored in (d)+3 when SM701 (Number of output characters selection) is off. When it is on, the value remains unchanged.

\*1 When the value is 0 or positive, 20H (space) is stored. When the value is negative, 2DH (-) is stored.

\*2 When the length of the numeric part is 4 digits or less, 20H (space) is stored in ASCII 10<sup>4</sup>.

\*3 When the length of the numeric part is 3 digits or less, 20H (space) is stored in ASCII 10<sup>3</sup>.

\*4 When the length of the numeric part is 2 digits or less, 20H (space) is stored in ASCII 10<sup>2</sup>.

\*5 When the length of the numeric part is 1 digit, 20H (space) is stored in ASCII 10<sup>1</sup>.

### Ex.

-12345 is set in (s) when the BINDA(P) instruction is used.

## ■Operation of when SM705 (Number of conversion digits selection) is on

Decimal ASCII data is stored right-justified in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s)                                                                                                                                    | Data of (d) to (d)+2                                                                                                                                                                                                                                                                                                                                                                                                                                                | Value of (s) | Data of (d) to (d)+2            |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |     |  |                       |  |  |                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |     |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |     |  |  |  |  |

ASCII 10<sup>4</sup>: Ten-thousands place of ASCII code

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- When the number of operation digits is less than the maximum number of digits (sign + 5 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Number of output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of operation digits is equal to the maximum number of digits (a sign + 5 digits), 00H is stored in (d)+3 when SM701 is off. (d)+3 remains unchanged if SM701 is on.

## Operation error

There is no operation error.

## Precautions

When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the BINDA(P)(\_U) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

[Example] Executing the BINDA(P) instruction when (s) is "-12345" and then executing another BINDA(P) instruction when (s) is "-67"

- (1) "-12345" is converted into a string.
- (2) "-67" is converted into a string.
- (3) A part of the previous conversion result remains in (d)+2.

To avoid this, create a program to clear the entire data storage areas (d)+0 to (d)+2 before executing the BINDA(P)(\_U) instruction.

- (4) "-12345" is converted into a string.
- (5) (d)+0 to (d)+2 are cleared.
- (6) "-67" is converted into a string.

# Converting 32-bit binary data to decimal ASCII

16

## DBINDA(P)(\_U)

These instructions convert 32-bit binary data to the decimal ASCII code.

## Processing details

- These instructions convert the digit in decimal notation of the 32-bit binary data in the device specified by (s) to the ASCII code, and store the converted data in the device number specified by (d) and later.
- The format of the decimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Storage format of (d)                                              | Reference                                                                       |
|-----------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Off             | Data is stored in a fixed number of digits (a sign + 10 digits)    | Page 739 Operation of when SM705 (Number of conversion digits selection) is off |
| On              | Each digit is stored left-justified depending on the value of (s). | Page 740 Operation of when SM705 (Number of conversion digits selection) is on  |

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the DBINDA(P) instruction is executed with a numeric value "-123456" stored in (s)

- When SM705 is off, the number of digits is fixed. The first character is a sign and it is 2DH(-) in the above example. (If (s) is 0 or positive, the first character is 20H (space).) The numeric part is right-justified. When the length of the numeric part is less than 10 digits, the ASCII code 20H (space) is stored for the ASCII code of the upper digit(s).
- When SM705 is on, data is left-justified. When the length of the numeric part is less than 10 digits, 00H is stored in the end.

## ■Operation of when SM705 (Number of conversion digits selection) is off

Decimal ASCII data is stored in a fixed number of digits in (d) to (d)+5.

ASCII S: Sign data of ASCII code\*<sup>1</sup>

ASCII 10<sup>9</sup>: Billions place of ASCII code\*<sup>2</sup>

ASCII 10<sup>8</sup>: Hundred-millions place of ASCII code\*<sup>3</sup>

⋮

ASCII 10<sup>1</sup>: Tens place of ASCII code\*<sup>4</sup>

ASCII 10<sup>0</sup>: Ones place of ASCII code

(1) 00H is stored in the upper byte of (d)+5 only when SM701 (Number of output characters selection) is off, and 20H (space) is stored when it is on.

\*<sup>1</sup> When the value is 0 or positive, 20H (space) is stored. When the value is negative, 2DH (-) is stored.

\*<sup>2</sup> When the length of the numeric part is 9 digits or less, 20H (space) is stored in ASCII 10<sup>9</sup>.

\*<sup>3</sup> When the length of the numeric part is 8 digits or less, 20H (space) is stored in ASCII 10<sup>8</sup>.

\*<sup>4</sup> When the length of the numeric part is 1 digit, 20H (space) is stored in ASCII 10<sup>1</sup>.

### Ex.

When -12345678 (signed) is specified in (s)

## ■Operation of when SM705 (Number of conversion digits selection) is on

Decimal ASCII data is stored right-justified in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s)                                                                                                                                    | Data of (d) to (d)+2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Value of (s) | Data of (d) to (d)+2            |       |     |    |     |                       |   |                                 |  |       |                       |   |                       |  |       |                       |   |                       |  |       |                       |   |                       |  |       |                       |   |                       |  |       |                |   |                       |  |                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |     |     |       |     |    |     |                       |   |                                 |  |       |                       |   |                       |  |       |                       |   |                       |  |       |                       |   |                       |  |       |                       |   |                       |  |       |     |  |  |  |

- When the number of operation digits is less than the maximum number of digits (a sign + 10 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Number of output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of operation digits is equal to the maximum number of digits (a sign + 10 digits), 00H is stored in the upper byte of (d)+5 if SM701 is off. 20H (space) is stored in the upper byte of (d)+5 if SM701 is on.

## Operation error

There is no operation error.

## Precautions

When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the DBINDA(P)(\_U) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

[Example] Executing the DBINDA(P) instruction when (s) is "-1234567890" and then executing another DBINDA(P) instruction when (s) is "-987654"

To avoid this, create a program to clear the entire data storage areas (d)+0 to (d)+5 before executing the DBINDA(P)(\_U) instruction.

# Converting 16-bit binary data to hexadecimal ASCII

## BINHA(P)

These instructions convert 16-bit binary data to the hexadecimal ASCII code.

## Processing details

- These instructions convert the digit in hexadecimal notation of the 16-bit binary data in the device specified by (s) to the ASCII code, and store the converted data in the device number specified by (d) and later.
- The format of the hexadecimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Storage format of (d)                                              | Reference                                                                       |
|-----------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Off             | Data is stored in a fixed number of digits (4 digits)              | Page 744 Operation of when SM705 (Number of conversion digits selection) is off |
| On              | Each digit is stored left-justified depending on the value of (s). | Page 744 Operation of when SM705 (Number of conversion digits selection) is on  |

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the BINHA(P) instruction is executed with the 16-bit binary data "0ABCH" stored in (s)

- When SM705 is off, the number of digits is fixed. Four digits of "0ABC" are converted into ASCII data and stored.
- When SM705 is on, data is left-justified. "0ABC" with the leading "0" omitted ("ABC") are converted into ASCII data and stored, and 00H is stored in the end.

■Operation of when SM705 (Number of conversion digits selection) is off

Hexadecimal ASCII data is stored in a fixed number of digits (4 digits) in (d).

ASCII □: ASCII code (□th digit)

(1) 00H is stored in (d)+2 when SM701 (Number of output characters selection) is off. When it is on, the value remains unchanged.

- The operation result to be stored in the device specified by (d) is processed as a 4-digit hexadecimal number. Therefore, 0 at the left side of the effective number of digits is processed as "0". (Zero padding)

Ex.

When 02A6H is stored in the device specified by (s)

■Operation of when SM705 (Number of conversion digits selection) is on

Hexadecimal ASCII data for the number of digits (up to 4 digits) without the leftmost "0" in the effective digits is stored right-justified in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s) | Data of (d) to (d)+1                                                                                                                                                                                                         | Value of (s)   | Data of (d) to (d)+1                                                                                                                                                                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0H to FH     | <ul style="list-style-type: none"><li>• The upper byte of (d) is filled with 00H.</li><li>• (d)+1 and later remain unchanged.</li></ul> <div><div>b15 ... b8 b7 ... b0</div><div>(d) 00H ASCII 1</div><div>(d)+1</div></div> | 10H to FFH     | <div>(d)+1 is filled with 00H.</div> <div><div>b15 ... b8 b7 ... b0</div><div>(d) ASCII 1 ASCII 2</div><div>(d)+1 00H</div></div>                                                                                                                                                     |
| 100H to FFFH | <div>The upper byte of (d)+1 are filled with 00H.</div> <div><div>b15 ... b8 b7 ... b0</div><div>(d) ASCII 2 ASCII 3</div><div>(d)+1 00H ASCII 1</div></div>                                                                 | 1000H to FFFFH | <div>(1) (d)+2 is filled with 00H when SM701 (Number of output characters selection) is off. (d)+2 remains unchanged if SM701 is on.</div> <div><div>b15 ... b8 b7 ... b0</div><div>(d) ASCII 3 ASCII 4</div><div>(d)+1 ASCII 1 ASCII 2</div><div>(d)+2 00H</div><div>(1)</div></div> |

ASCII □: ASCII code (□th digit)

- When the number of digits is less than the maximum number of digits (4 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Number of output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of digits is equal to the maximum number of digits (4 digits), 00H is stored in (d)+2 when SM701 is off. (d)+2 remains unchanged if SM701 is on.

Operation error

There is no operation error.

## Precautions

When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the BINHA(P) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

[Example] Executing the BINHA(P) instruction when (s) is "2A6F" and then executing another BINHA(P) instruction when (s) is "9"

- (1) "2A6F" is converted into a string.
- (2) "9" is converted into a string.
- (3) A part of the previous conversion result remains in (d)+1.

To avoid this, create a program to clear the entire data storage areas (d)+0 and (d)+1 before executing the BINHA(P) instruction.

- (4) "2A6F" is converted into a string.
- (5) (d)+0 to (d)+1 are cleared.
- (6) "9" is converted into a string.

# Converting 32-bit binary data to hexadecimal ASCII

## DBINHA(P)

These instructions convert 32-bit binary data to the hexadecimal ASCII code.

## Processing details

- These instructions convert the digit at each place in hexadecimal notation of the 32-bit binary data specified by (s) to the ASCII code, and store the converted data in the device number specified by (d) and later.
- The format of the decimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Storage format of (d)                                              | Reference                                                                       |
|-----------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Off             | Data is stored in a fixed number of digits (8 digits)              | Page 748 Operation of when SM705 (Number of conversion digits selection) is off |
| On              | Each digit is stored left-justified depending on the value of (s). | Page 748 Operation of when SM705 (Number of conversion digits selection) is on  |

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the DBINHA(P) instruction is executed with a 32-bit binary data "000ABCDEH" stored in (s)

- When SM705 is off, the number of digits is fixed. Eight digits of "000ABCDE" are converted into ASCII data and stored.
- When SM705 is on, data is left-justified. The effective digits "000ABCDE" with the leading "0"s omitted ("ABCDE") are converted into ASCII data and stored, and 00H is stored in the end.

■Operation of when SM705 (Number of conversion digits selection) is off

Hexadecimal ASCII data is stored in a fixed number of digits (8 digits) in (d) to (d)+3.

ASCII □: ASCII code (□th digit)

(1) 00H is stored in (d)+4 when SM701 (Number of output characters selection) is off. When it is on, the value remains unchanged.

- The operation result to be stored in the device specified by (d) is processed as an 8-digit hexadecimal number. Therefore, 0 at the left side of the effective number of digits is processed as "0". (Zero padding)

**Ex.**

When 03AC625EH is stored in the device specified by (s)

■Operation of when SM705 (Number of conversion digits selection) is on

Hexadecimal ASCII data for the number of digits (up to 8 digits) without the leftmost "0" in the effective digits is stored right-justified in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s)          | Data of (d) to (d)+3                                                                                                                                                                                                                                                                                                                                                          | Value of (s) | Data of (d) to (d)+3 |         |       |         |         |       |         |         |       |     |         |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |     |         |         |       |         |         |       |         |         |       |         |         |       |     |  |

ASCII □: ASCII code (□th digit)

- When the number of digits is less than the maximum number of digits (8 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Number of output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of digits is equal to the maximum number of digits (8 digits), 00H is stored in (d)+4 when SM701 (Number of output characters selection) is off. (d)+4 does not change if SM701 (Number of output characters selection) is on.

## Operation error

There is no operation error.

## Precautions

When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the DBINHA(P) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

[Example] Executing the DBINHA(P) instruction when (s) is "13AC625E" and then executing another DBINHA(P) instruction when (s) is "F9E8D"

- (1) "13AC625E" is converted into a string.
- (2) "F9E8D" is converted into a string.
- (3) A part of the previous conversion result remains in (d)+3.

To avoid this, create a program to clear the entire data storage areas (d)+0 to (d)+3 before executing the DBINHA(P) instruction.

- (4) "13AC625E" is converted into a string.
- (5) (d)+0 to (d)+3 are cleared.
- (6) "F9E8D" is converted into a string.

# Converting 16-bit binary data to string data

## STR(P)(\_U)

These instructions convert 16-bit binary data to a string by adding a decimal point to the specified place of the data.

| Ladder | ST                                              |                                                     |
|--------|-------------------------------------------------|-----------------------------------------------------|

## Processing details

- These instructions add a decimal point to the 16-bit binary data in the device specified by (s2) at the location specified by (s1), convert the data to string data, and store the converted data in the device areas specified by (d) and later.

### Ex.

When converting data "-123" in (s2) into a string assuming that the number of decimal places is one ("-12.3")

- When storing the decimal part in (d), the total number of digits that can be specified by (s1) is 4 to 8. The number of digits in the decimal part that can be specified by (s1)+1 is 1 to 5. Note that the number of digits in the decimal part must be equal to or smaller than the total number of digits minus 3.
- When not storing the decimal part in (d), the total number of digits that can be specified by (s1) is 2 to 8. The number of digits in the decimal part that can be specified by (s1)+1 cannot be set.

- The converted string data are stored in the device areas specified by (d) and later as shown below.
- As sign data, "20H" (space) is stored if the 16-bit binary data is positive, and "2DH" (-) is stored if the data is negative.
- If the number of digits in the decimal part is set to other than 0, "2EH" (.) is automatically stored at the position before the specified number of digits. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- If the specified number of digits in the decimal part is greater than the number of digits of the 16-bit binary data, 0s are automatically added and the data is regarded as "0.□□□□".

- If the total number of digits excluding the sign and the decimal point is greater than the number of digits of the 16-bit binary data, "20H" (space) is stored between the sign and the numeric value. If the number of digits of the 16-bit binary data is greater, an error occurs.

- The value "00H" is automatically stored at the end of the converted string.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Processing details

- These instructions add a decimal point to the 32-bit binary data in the device specified by (s2) at the location specified by (s1), convert the data to string data, and store the converted data in the device areas specified by (d) and later.

**Ex.**

When converting data "-654321" in (s2) into a string assuming that the number of decimal places is three ("-654.321")

- When storing the decimal part in (d), the total number of digits that can be specified by (s1) is 4 to 13. The number of digits in the decimal part that can be specified by (s1)+1 is 1 to 10. Note that the number of digits in the decimal part must be equal to or smaller than the total number of digits minus 3.
- When not storing the decimal part in (d), the total number of digits that can be specified by (s1) is 2 to 13. The number of digits in the decimal part that can be specified by (s1)+1 cannot be set.

- The converted string data are stored in the device areas specified by (d) and later as shown below.
- As sign data, 20H (space) is stored if the 32-bit binary data is positive, and 2DH (-) is stored if the data is negative.
- If the number of digits in the decimal part is set to other than 0, "2EH" (.) is automatically stored at the position before the specified number of digits. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- If the specified number of digits in the decimal part is greater than the number of digits of the 32-bit binary data, 0s are automatically added and the data is regarded as "0.□□□□".

- If the total number of digits excluding the sign and the decimal point is greater than the number of digits of the 32-bit binary data, 20H (space) is stored between the sign and the numeric value. If the number of digits of the 32-bit binary data is greater, an error occurs.

- The value "00H" is automatically stored at the end of the converted string.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# Converting BCD 4-digit data to decimal ASCII code

## BCDDA(P)

These instructions convert BCD 4-digit data to the ASCII code.

| Ladder | ST                                                  |
|--------|-----------------------------------------------------|
|        | <pre>ENO:=BCDDA(EN,s,d); ENO:=BCDDAP(EN,s,d);</pre> |

## FBD/LD

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| BCDDA       |                     |
| BCDDAP      |                     |

## Setting data

## Description, range, data type

| Operand | Description                                    | Range     | Data type   | Data type (label) |
|---------|------------------------------------------------|-----------|-------------|-------------------|
| (s)     | BCD data used for ASCII conversion             | 0 to 9999 | BCD 4-digit | ANY16             |
| (d)     | Start device for storing the conversion result | —         | String      | ANYSTRING_SINGLE  |
| EN      | Execution condition                            | —         | Bit         | BOOL              |
| ENO     | Execution result                               | —         | Bit         | BOOL              |

## Applicable devices

## Processing details

- These instructions convert the numerical value of each digit of the BCD 4-digit data in the device specified by (s) to the ASCII code, and store the converted data in the device number specified by (d) and later.
- The format of the hexadecimal ASCII data to be stored in (d) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Storage format of (d)                                              | Reference                                                                       |
|-----------------|--------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Off             | Data is stored in a fixed number of digits (4 digits)              | Page 758 Operation of when SM705 (Number of conversion digits selection) is off |
| On              | Each digit is stored left-justified depending on the value of (s). | Page 758 Operation of when SM705 (Number of conversion digits selection) is on  |

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the BCDDA(P) instruction is executed with BCD 4-digit data "0123" stored in (s)

- When SM705 is off, the number of digits is fixed. The leading "0" of "0123" is converted into 20H (space) and stored.
- When SM705 is on, data is left-justified. "0123" with the leading "0" omitted ("123") is converted into ASCII data and stored, and 00H is stored in the end.

## ■Operation of when SM705 (Number of conversion digits selection) is off

Decimal ASCII data is stored in a fixed number of digits (4 digits) in (d) to (d)+1.

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

(1) 00H is stored in (d)+2 when SM701 (Number of output characters selection) is off. When it is on, the value remains unchanged.

- 20H (space) is stored for the leading "0"s at the left of the effective number of digits of the operation result stored in the device specified by (d). (Zero-suppression) For "0050", "00" becomes 20H (space) and "50" is the effective number of digits.

### Ex.

When 9105 is specified in (s)

## ■Operation of when SM705 (Number of conversion digits selection) is on

Decimal ASCII data for the number of digits (up to 4 digits) without the leftmost "0" in the effective digits is stored in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s) | Data of (d) to (d)+1                                                                                                                                                                                                                         | Value of (s)   | Data of (d) to (d)+1                                                                                                                                                                                                                                                                                                                 |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0H to 9H     | <ul style="list-style-type: none"> <li>The upper byte of (d) is filled with 00H.</li> <li>(d)+1 and later remain unchanged.</li> </ul> <div> <div>b15 ... b8 b7 ... b0</div> <div>(d) 00H ASCII 10<sup>0</sup></div> <div>(d)+1</div> </div> | 10H to 99H     | (d)+1 is filled with 00H. <div> <div>b15 ... b8 b7 ... b0</div> <div>(d) ASCII 10<sup>0</sup> ASCII 10<sup>1</sup></div> <div>(d)+1 00H</div> </div>                                                                                                                                                                                 |
| 100H to 999H | The upper byte of (d)+1 are filled with 00H. <div> <div>b15 ... b8 b7 ... b0</div> <div>(d) ASCII 10<sup>1</sup> ASCII 10<sup>2</sup></div> <div>(d)+1 00H ASCII 10<sup>0</sup></div> </div>                                                 | 1000H to 9999H | (1) (d)+2 is filled with 00H when SM701 (Number of output characters selection) is off. (d)+2 remains unchanged if SM701 is on. <div> <div>b15 ... b8 b7 ... b0</div> <div>(d) ASCII 10<sup>2</sup> ASCII 10<sup>3</sup></div> <div>(d)+1 ASCII 10<sup>0</sup> ASCII 10<sup>1</sup></div> <div>(d)+2 00H</div> <div>(1)</div> </div> |

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- When the number of digits is less than the maximum number of digits (4 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Number of output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of digits is equal to the maximum number of digits (4 digits), 00H is stored in (d)+2 when SM701 is off. (d)+2 remains unchanged if SM701 is on.

## Operation error

| Error code (SD0) | Description                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | Data in the device specified by (s) is out of the range, 0 to 9999.                                                                                          |
| 3286H            | The entire string that was converted in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored. |

## Precautions

When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the BCDDA(P) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

[Example] Executing the BCDDA(P) instruction when (s) is "9105H" and then executing another BCDDA(P) instruction when (s) is "0007H"

To avoid this, create a program to clear the entire data storage areas (d)+0 and (d)+1 before executing the BCDDA(P) instruction.

# Converting BCD 8-digit data to decimal ASCII code

## DBCDDA(P)

These instructions convert BCD 8-digit data to the ASCII code.

### ■ Operation overview

The following figure shows the operation when SM705 (Number of conversion digits selection) is off and on.

**Ex.**

When the DBCDDA(P) instruction is executed with BCD 8-digit data "00012345" stored in (s)

- When SM705 is off, the number of digits is fixed. Each of the leading "0"s of "00012345" is converted into 20H (space) and stored.
- When SM705 is on, data is left-justified. "00012345" with the leading "0"s omitted ("12345") is converted into ASCII data and stored, and 00H is stored in the end.

■Operation of when SM705 (Number of conversion digits selection) is off

Decimal ASCII data is stored in a fixed number of digits (8 digits) in (d) to (d)+3.

ASCII 10<sup>7</sup>: Ten-millions place of ASCII code

ASCII 10<sup>6</sup>: Millions place of ASCII code

⋮

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

(1) 00H is stored in (d)+4 when SM701 (Number of output characters selection) is off. When it is on, the value remains unchanged.

- 20H (space) is stored for the leading "0"s at the left of the effective number of digits of the operation result stored in the device specified by (d). (Zero-suppression) For "00012098", "000" becomes 20H (space) and "12098" is the effective number of digits.

Ex.

When 01234056 is specified in (s)

## ■Operation of when SM705 (Number of conversion digits selection) is on

Decimal ASCII data for the number of digits (up to 8 digits) without the leftmost "0" in the effective digits is stored in (d).

The following figures show an example of a value of (s) and a value stored in (d).

| Value of (s)         | Data of (d) to (d)+3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Value of (s) | Data of (d) to (d)+3 |                       |     |    |     |    |     |                       |  |  |                       |  |  |       |                       |  |  |                       |  |  |       |                       |  |  |                       |  |  |       |     |  |  |                       |  |  |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |     |     |    |    |     |    |     |                       |  |  |                       |  |  |       |                       |  |  |                       |  |  |       |                       |  |  |                       |  |  |       |                       |  |  |                       |  |  |       |     |  |  |  |  |  |

ASCII 10<sup>7</sup>: Ten-millions place of ASCII code

ASCII 10<sup>6</sup>: Millions place of ASCII code

⋮

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- When the number of digits is less than the maximum number of digits (8 digits), 00H is stored in the end of the string regardless of the status (on/off) of SM701 (Number of output characters selection). If the end of the string is the lower byte, 00H is also stored in the upper byte.
- When the number of digits is equal to the maximum number of digits (8 digits), 00H is stored in (d)+4 when SM701 (Number of output characters selection) is off. (d)+4 does not change if SM701 (Number of output characters selection) is on.

## Operation error

| Error code (SD0) | Description                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | Data in the device specified by (s) is out of the range, 0 to 99999999.                                                                                      |
| 3286H            | The entire string that was converted in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored. |

## Precautions

When SM705 (Number of conversion digits selection) is on, the operation result is stored in (d) for the effective number of digits. Therefore, when the DBCDDA(P) instruction is executed successively and the operation result for each execution is stored in the same device, a part of the previous operation result may not be overwritten by the succeeding result and can remain in (d).

[Example] Executing the DBCDDA(P) instruction when (s) is "91234056H" and then executing another DBCDDA(P) instruction when (s) is "00001234H"

(1) "91234056" is converted into a string.

(2) "1234" is converted into a string.

(3) A part of the previous conversion result remains in (d)+3.

To avoid this, create a program to clear the entire data storage areas (d)+0 to (d)+3 before executing the DBCDDA(P) instruction.

(4) "91234056" is converted into a string.

(5) (d)+0 to (d)+3 are cleared.

(6) "1234" is converted into a string.

# Converting single-precision real number to string data

## ESTR(P)

These instructions convert single-precision real number data to a string according to the display specification.

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|
|        | <pre>ENO:=ESTR(EN,s1,s2,d); ENO:=ESTRP(EN,s1,s2,d);</pre> |

## Processing details

- These instructions convert the single-precision real number data stored in the device specified by (s1) to a string according to the display specification stored in the device number specified by (s2) and later, and store the converted data in the device number specified by (d) and later.
- The type of the converted data varies depending on the display specification stored in the device specified by (s2).

|        |                                               |
|--------|-----------------------------------------------|
| (s2)   | 0: Decimal point format<br>1: Exponent format |
| (s2)+1 | Total number of digits                        |
| (s2)+2 | Number of digits in the decimal part          |

### ■Decimal point format

- When 0 is specified in (s2), the decimal point format is used.

- When storing the decimal part in (d), the total number of digits that can be specified by (s2) + 1 is the total number of digits (maximum of 24)  $\geq$  (number of digits in the integral part<sup>\*1</sup> + number of digits in the decimal part + 2). The number of digits in the decimal part that can be specified by (s2)+2 is 0 to 7. Note that the number of digits in the decimal part must be equal to or smaller than the total number of digits minus 3.

\*1 Indicates the number of digits in the integral part of the 32-bit floating point real number data in the device specified by (s1).

- When not storing the decimal part in (d), the total number of digits that can be specified by (s2) + 1 is the total number of digits (maximum of 24)  $\geq$  (number of digits in the integral part<sup>\*2</sup> + 1). The number of digits in the decimal part that can be specified by (s2)+2 cannot be set.

\*2 Indicates the number of digits in the integral part of the 32-bit floating point real number data in the device specified by (s1).

- The converted string data are stored in the device areas specified by (d) and later as shown below.

- As sign data, 20H (space) is stored if the single-precision real number data is positive, and 2DH (-) is stored if the data is negative.
- If the decimal part of the single-precision real number data is not stored within the range of the number of digits in the decimal part, the lower decimal digits are rounded off.

- (1) Total number of digits
- (2) Number of digits in the decimal part
- (3) Rounded off.

- If the number of digits in the decimal part is set to a value other than 0, 2EH (.) is automatically stored at the position of the specified number of digits in the decimal part plus 1. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- (1) Total number of digits
- (2) Number of digits in the decimal part
- (3) Automatically added.

- If the number of digits excluding the sign, decimal point, and decimal part from the total number of digits is greater than the number of digits in the integral part of single-precision real number data, 20H (space) is stored between the sign and integral part.

- (1) Total number of digits
- (2) Number of digits in the decimal part
- (3) Filled with 20H (space).

- The value "00H" is automatically stored at the end of the converted string.
- The number of digits in the integral part of the 32-bit floating point real number data in the device specified by (s1) can be 1 to 16.

## ■Exponential format

- When 1 is specified in (s2), the exponential format is used.

- When storing the decimal part in (d), the total number of digits that can be specified by (s2) + 1 is the number of digits (maximum of 24)  $\geq$  (number of digits in the decimal part+7). The number of digits in the decimal part that can be specified by (s2)+2 is 0 to 7. Note that the number of digits in the decimal part must be equal to or smaller than the total number of digits minus 7.
- When not storing the decimal part in (d), the total number of digits that can be specified by (s2) + 1 is the number of digits (maximum of 24)  $\geq$  6. The number of digits in the decimal part that can be specified by (s2)+2 cannot be set.

- The converted string data are stored in the device areas specified by (d) and later as shown below.
- As sign data in the integral part, 20H (space) is stored if the single-precision real number data is positive, and 2DH (-) is stored if the data is negative.
- The integral part is fixed to one digit. 20H (space) is stored between the integral part and sign.

- (1) Total number of digits
- (2) Fixed to 1 digit
- (3) Filled with 20H (space).

- If the decimal part of the single-precision real number data is not stored within the range of the number of digits in the decimal part, the lower decimal digits are rounded off.

- (1) Total number of digits
- (2) Number of digits in the decimal part
- (3) Rounded down.

- If the number of digits in the decimal part is set to a value other than 0, 2EH (.) is automatically stored at the position of the specified number of digits in the decimal part plus 1. If the number of digits in the decimal part is 0, "2EH" (.) is not stored.

- (1) Total number of digits
- (2) Number of digits in the decimal part
- (3) Automatically added.

- As sign data in the exponent part, 2BH (+) is stored if the exponent is positive, and 2DH (-) is stored if it is negative.
- The exponent part is fixed to two digits. When the exponent part is one digit, 30H(0) is stored between the exponent part and sign.

- (1) Total number of digits
- (2) Fixed to 2 digits

- The value "00H" is automatically stored at the end of the converted string.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

\*1 Indicates the number of digits in the integral part of the 32-bit floating point real number data in the device specified by (s1).

# Converting hexadecimal binary data to hexadecimal ASCII code

## INT2ASC(P)

These instructions convert 16-bit binary data to the hexadecimal ASCII code and store it in any specified range.

| Ladder | ST                                                         |

- Converts the 16-bit binary data in the device number specified by (s) and later to hexadecimal ASCII, and stores the converted data by the number of characters in the device specified by (n) in the device number specified by (d) and later.

- Setting the number of bytes by (n) automatically determines the range of binary data in the device specified by (s) and the range of the device specified by (d) for storing the string data.
- Processing is performed normally even if the device range in which the binary data to be converted and the device range for storing the converted binary data are overlapping.

- If the number of characters in the device specified by (n) is an odd number, 00H is automatically stored in the upper 8 bits of the last device number among device numbers for storing the converted string data.

(1) 00H is automatically stored.

- If the number of characters in the device specified by (n) is 0, no processing is performed.

## Operation error

| Error code (SD0) | Description                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3285H            | An out-of-range value is set to (n). <ul style="list-style-type: none"> <li>The specified number of characters is not between 0 and 16383.</li> </ul> |

# Converting and concatenating multiple data strings

## SPF(P)

Multiple data is converted to a string according to the specified display format, the string is concatenated with any string, and they are output as a single string.

### Restriction

Before using the instruction, check the versions of the controller and engineering tool.

 User's manual for the controller used

## Processing details

- This instruction converts data stored in the device number specified by (s2) and later into strings according to the display format specified by (s1). Then, the strings are concatenated with a given string stored in (s1), and they are stored as a single string in the device number specified by (d) and later. The given string can be omitted, allowing only the data stored in the device number specified by (s2) and later to be concatenated.
- The display format is as follows: Specifiers are combined in the order starting from "%", followed by [Flag], [Minimum field width], [Accuracy], [Acquisition data size], and [Conversion specifier]. The specifiers are stored together with the concatenation target string in (s1). The following table lists the display format selection items that can be used. If the order of the display format items is incorrect, an error occurs.

| Display format        | Specifier <sup>*1</sup>            | Description                                                                                                                                                                                                                                                      | Details                        |
|-----------------------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Flag                  | -, +, " " (space), #, and 0        | Modifies the string to be output to (d) according to the specified specifier.                                                                                                                                                                                    | Page 775 Flag                  |
| Minimum field width   | Any numerical value                | Specifies the total number of characters to be output to (d), including the sign of the converted string, decimal point, exponent part, and " " (space). When this item is omitted, the number of characters for the retrieved data is specified for the output. | Page 776 Minimum field width   |
| Accuracy              | "." (period) numerical value       | Specifies the number of characters to be output to (d) with [Conversion specifier] from the data stored in (s2).                                                                                                                                                 | Page 777 Accuracy              |
| Acquisition data size | w, q                               | Specifies how many words of the data stored in (s2) are to be converted and output to (d). When this item is omitted, the data is retrieved in units of one word.                                                                                                | Page 779 Acquisition data size |
| Conversion specifier  | d, u, x, X, o, s, c, f, e, E, g, G | Specifies the output format of the string to be output to (d).                                                                                                                                                                                                   | Page 780 Conversion specifier  |

<sup>\*1</sup> Specifiers are case-sensitive.

- [Flag], [Minimum field width], [Accuracy], and [Acquisition data size] can be omitted.
- Only if "%" is output as a character, [Conversion specifier] can be omitted. When "%" is stored in (s1) and output as a string, "%" will be stored in (d) as a string. The data stored following "%" is output as a character up to the next display format.

### Ex.

When "%d%" is stored in (s1) and "100" is stored in the device specified by (s2), "100%" is stored in the device specified by (d).

### Ex.

When "%ABC%d" is stored in (s1) and "100" is stored in the device specified by (s2), "%ABC100" is stored in the device specified by (d).

- If the converted string (d) ends with an even number of bytes, the NULL code "00H" is stored in the device (upper 8 bits and lower 8 bits) following the last device of the string. If the converted string (d) ends with an odd number of bytes, the NULL code "00H" is stored in the last device (upper 8 bits) of the string.

**Ex.**

When the SPF(P) instruction is executed while the data listed below is stored, the string stored in D100 and later is "AB1234CD0xbc614e1.234568".

| Operand | Stored data                                                                                                                                                                                                                                |                                                |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| (s1)    | AB%dCD%#wx%qf (string)<br>• The following display format is specified for the stored string.<br>AB (outputting the string) %d (D1 display format) CD (outputting the string) %#wx (D2 and D3 display format) %qf (D4 to D7 display format) |                                                |
| (s2)    | D1                                                                                                                                                                                                                                         | 1234 (decimal)                                 |
|         | D2 to D3                                                                                                                                                                                                                                   | 12345678 (decimal)                             |
|         | D4 to D7                                                                                                                                                                                                                                   | 1.2345678901234 (double-precision real number) |
| (d)     | D100                                                                                                                                                                                                                                       |                                                |

(1): The string "AB" is output.

(2): The display format: [Acquisition data size] = (Omitted), [Conversion specifier] = d Data is obtained from (s2) in units of one word, and output as a signed decimal number.

(3): The string "CD" is output.

(4): The display format: [Flag] = #, [Acquisition data size] = w, [Conversion specifier] = x Data is obtained from (s2)+1 in units of two words, prefixed with "0x", and output as an unsigned hexadecimal number.

(5): The display format: [Accuracy] = (Omitted), [Acquisition data size] = q, [Conversion specifier] = f Data is obtained from (s2)+3 in units of four words, and output as a double-precision real number in decimal notation. Since the description of [Accuracy] is omitted, a value with six digits after the decimal point is output, and the last digit of the output string is rounded off.

## ■Flag

This item modifies the string to be output to (d) according to conditions.

| Specifier   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Multiple specifiers can be specified for [Flag]. There are no restrictions on the order to be used. However, when "+" and " " (space) are concurrently used, the content of the specifier "+" takes a priority for the output. If the same specifier is used, the second and subsequent specifications are ignored. If the specifiers "-" and "0" are specified simultaneously, the specifier "0" is ignored.

### Ex.

When "-" and " " (space) are used

**Ex.**

When "#" and "-" are used

**Ex.**

When "+", "-", " " (space), and "#" are used

**■Minimum field width**

This item specifies the total number of characters to be output to (d), including the sign of the converted string, decimal point, exponent part, and " " (space).

| Specifier       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## ■Accuracy

Specifies the number of characters to be output to (d) with [Conversion specifier] from the data stored in (s2).

To indicate the accuracy, add the numerical value after "." (period). When only "." (period) is described and the numerical value is omitted, the operation is the same as when ".0" is specified.

| Specifier                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

■Acquisition data size

This item specifies how many words of the data stored in (s2) are to be converted and output to (d).

| Specifier | Description                                                                                                                                                                                                                                                                                                                   |

| f         | Outputs a string in decimal notation. The maximum number of significant digits will be 7 for single-precision real numbers and 15 for double-precision real numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| e         | Outputs a string in exponential notation, with the exponent indicated by "e". The maximum number of significant digits will be 7 for single-precision real numbers and 15 for double-precision real numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| E         | Outputs a string in exponential notation, with the exponent indicated by "E". The maximum number of significant digits will be 7 for single-precision real numbers and 15 for double-precision real numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Specifier | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

When "f", "e", "E", "g", or "G" is used in [Conversion specifier], the output format can be selected from single-precision real number or double-precision real number by the specifier of [Acquisition data size]. When [Acquisition data size] is specified as "w", a single-precision real number is output, and when [Acquisition data size] is specified as "q", a double-precision real number is output.

**Ex.**

To output as a single-precision real number

**Ex.**

To output as a double-precision real number

## Precautions

The combination of display format items and the format of the data to be converted must always match. Otherwise, an unintended string will be output.

### Ex.

When the conversion target data is string data but the display format is numerical data

### Ex.

When the conversion target data is numerical data but the display format is string data

## ■Flag

- When [Conversion specifier] is "s", the specified [Flag] is ignored.
- When [Minimum field width] is equal to or less than the number of converted characters obtained from (s2), the specifier "-" is ignored.
- When [Conversion specifier] is "u", "x", "X", "o", "s", or "c", the specifiers "+" and " " (space) are ignored.
- When [Conversion specifier] is "d", "u", "s", or "c", or when [Conversion specifier] is specified as "o", "x", or "X" and "0" is specified in (s2), the specifier "#" is ignored.

### Ex.

When "o" is specified in [Conversion specifier] and "#" is specified in [Flag], the output is as follows.

### Ex.

When "x" is specified in [Conversion specifier] and "#" is specified in [Flag], the output is as follows.

- Ignored if a value other than 0 or a positive number is output when "+" and " " (space) are used.
- "-" is added at the beginning when "+" is not specified and a negative number is output.

## ■Minimum field value

If the specified [Minimum field width] exceeds 255 characters, an error (error code: 329CH) occurs.

## ■Accuracy

- If the specified [Accuracy] exceeds 255 characters, an error (error code: 329CH) occurs.
- When [Conversion specifier] is "g" or "G", "0"s at the end after the decimal point are not output. "." (period) is also not displayed if there is no numerical value after the decimal point.

### Ex.

When the number of significant digits is six, 0s at the end after the decimal point (0s at the fourth and fifth places after the decimal point) are not output.

### Ex.

When the number of significant digits is five, "." (period) is not output because all the digits after the decimal point are 0s (no numerical values).

- When [Conversion specifier] is "f", "e", "E", "g", or "G" and the numerical value specified in [Accuracy] is larger than the maximum number of significant digits of the output result, the value is output with the maximum number of significant digits.

### Ex.

When "f" is specified in [Conversion specifier] and the numerical value specified in [Accuracy] is larger than the maximum number of significant digits of the double-precision real number, the value is output with the maximum number of significant digits (15 digits) of the double-precision real number.

### Ex.

When "e" is specified in [Conversion specifier] and the numerical value specified in [Accuracy] is larger than the maximum number of significant digits of the double-precision real number, the value is output with the maximum number of significant digits (15 digits) of the double-precision real number.

**Ex.**

When "g" is specified in [Conversion specifier], the numerical value specified in [Accuracy] is larger than the maximum number of significant digits of the double-precision real number, and the number of digits of the numerical value stored in (s2) is equal to or less than the maximum number of significant digits, "0"s at the end after the decimal point are not output.

**Ex.**

When "g" is specified in [Conversion specifier], the numerical value specified in [Accuracy] is larger than the maximum number of significant digits of the double-precision real number, and the number of digits of the numerical value stored in (s2) is equal to or larger than the maximum number of significant digits, the value is output with the maximum number of significant digits (15 digits) which is obtained by rounding off the 16th digit.

**Ex.**

When "g" is specified in [Conversion specifier], the numerical value specified in [Accuracy] is larger than the maximum number of significant digits of the double-precision real number, and the value is output in exponential notation, "0"s at the end after the decimal point are not output.

- When "f", "e", or "E" is specified in [Conversion specifier], ".0" is specified in [Accuracy], and "#" is not specified in [Flag], the digits after the decimal point are not output.

**Ex.**

When [Conversion specifier] is "f", the expression is as follows if ".0" is specified in [Flag].

**Ex.**

When [Conversion specifier] is "e", the expression is as follows if ".0" is specified in [Flag].

- When [Conversion specifier] is "d", "f", "e", "E", "g", or "G", the sign of the converted string is not included in the number of output characters specified in [Accuracy].

**Acquisition data size**

- When [Conversion specifier] is "s" or "c", the specified [Acquisition data size] is ignored.
- When [Conversion specifier] is "f", "e", "E", "g", or "G", always specify "w" or "q" in [Acquisition data size]. If the description is omitted, an error (error code: 3299H) occurs.

**Conversion specifier**

When a string is output in exponential notation, an exponent with two or more digits is output.

**Ex.**

When the data stored in (s2) is expressed exponentially and the number of digits of the exponent part is two, the exponent part is output as two digits as follows.

**Ex.**

When the data stored in (s2) is expressed exponentially and the number of digits of the exponent part is three, the exponent part is output as three digits as follows.

## Operation error

# Converting Unicode string to Shift JIS string

16

## WS2SJIS(P)

These instructions convert a Unicode string to a Shift JIS string.

| Ladder                                                                            | ST                                                      |
|-----------------------------------------------------------------------------------|---------------------------------------------------------|
|  | <pre>ENO:=WS2SJIS(EN,s,d); ENO:=WS2SJISP(EN,s,d);</pre> |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Execution condition

| Instruction | Execution condition                                                               |

|---------|----------------------------------|-----|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | ○  | —      |
| (d)     | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions convert the Unicode string in the device specified by (s) to the shift JIS string, and stores the converted data in the device specified by (d).
- The Unicode string in the device specified by (s) should be specified in little endian.

**Ex.**

A Unicode string "6587H" is specified with "6587H".

- The shift JIS string in (d) is stored in big endian.

**Ex.**

A shift JIS string "95B6H" is specified with "B695H".

- When a byte order mark is not used, conversion from Unicode to shift JIS occurs as follows.

- When a byte order mark (FEFFH) is added, conversion from Unicode to shift JIS occurs as follows.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                       |

| (d)     | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions convert the shift JIS string in the device specified by (s) to a Unicode string, and store the converted data in the device specified by (d).
- The shift JIS string in the device specified by (s) should be specified in big endian.

**Ex.**

A shift JIS string "95B6H" is specified with "B695H".

- The Unicode string in (d) is stored in little endian.

**Ex.**

A Unicode string "6587H" is specified with "6587H".

- The SJIS2WS(P) instruction does not add a byte order mark to the beginning of the data in the device specified by (d). To add a byte order mark, use the SJIS2WSB(P) instruction.

Page 793 SJIS2WSB(P)

- The following figure shows the operation for converting shift JIS to Unicode.

## Operation error

| Error code (SD0) | Description                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H            | The ranges of data in the devices specified by (s) and (d) are overlapping.                                                                                  |
| 3281H            | The range of data in the device specified by (s) includes a character code that cannot be converted.                                                         |
| 3285H            | The string in the device specified by (s) exceeds 16383 characters.*1                                                                                        |
| 3286H            | The entire string that was converted in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored. |

\*1 A two-byte character such as a kanji character represented in shift JIS code should be counted as 2.

# Converting shift JIS string to Unicode (with byte order mark)

## SJIS2WSB(P)

These instructions convert a shift JIS string to a Unicode string, and adds a byte order mark to the start of the converted data.

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|

## Processing details

- These instructions convert the shift JIS string in the device specified by (s) to the Unicode string, add a byte order mark to the start of the converted data, and store it in the device specified by (d).
- The shift JIS string in the device specified by (s) should be specified in big endian.

**Ex.**

A shift JIS string "95B6H" is specified with "B695H".

- The Unicode string in (d) is stored in little endian.

**Ex.**

A Unicode string "6587H" is specified with "6587H".

- The following figure shows the operation for converting shift JIS to Unicode.

## Operation error

| Error code (SD0) | Description                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H            | The ranges of data in the devices specified by (s) and (d) are overlapping.                                                                                  |
| 3281H            | The range of data in the device specified by (s) includes a character code that cannot be converted.                                                         |
| 3285H            | The string in the device specified by (s) exceeds 16383 characters.*1                                                                                        |
| 3286H            | The entire string that was converted in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored. |

\*1 A two-byte character such as a kanji character represented in shift JIS code should be counted as 2.

## Detecting a string length

### LEN(P)

These instructions detect the length of the specified string.

| Ladder                                                                            | ST <sup>*1</sup>   |
|-----------------------------------------------------------------------------------|--------------------|
|  | ENO:=LENP(EN,s,d); |

| FBD/LD <sup>*1</sup>                                                              |
|-----------------------------------------------------------------------------------|
|  |

<sup>\*1</sup> The LEN instruction does not support the ST and FBD/LD. Use the standard function, LEN.

 Page 1371 LEN(\_E)

### ■Execution condition

| Instruction | Execution condition                                                                |
|-------------|------------------------------------------------------------------------------------|
| LEN         |   |
| LENP        |  |

### Setting data

### ■Description, range, data type

| Operand | Description                                                        | Range | Data type            | Data type (label) |
|---------|--------------------------------------------------------------------|-------|----------------------|-------------------|
| (s)     | Character string or the start device containing the string         | —     | String               | ANYSTRING_SINGLE  |
| (d)     | Number of the device for storing the length of the detected string | —     | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                                | —     | Bit                  | BOOL              |
| ENO     | Execution result                                                   | —     | Bit                  | BOOL              |

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□G□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | ○  | —      |

## Processing details

These instructions detect the length of the string in the device specified by (s) and store it in the device number specified by (d) and later. The data stored in device numbers starting from the one specified by (s) to the one containing 00H is processed as a string.

### Ex.

When "ABCDEFGHI" is stored in the device specified by (s) and later

## Operation error

| Error code (SD0) | Description                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (00H) set in the assignment range of the relevant device/label for the device number specified by (s) and later. |
| 3285H            | The number of characters in the string specified by (s) exceeds 16383.                                                                 |

## Extracting string data from the right

### RIGHT(P)

These instructions extract (n) characters of data from the right of string data.

| Ladder   | ST*1                   |
|----------|------------------------|
|          | ENO:=RIGHTP(EN,s,n,d); |
| FBD/LD*1 |                        |
|          |                        |

\*1 The RIGHT instruction does not support the ST and FBD/LD. Use the standard function, RIGHT.

Page 1373 LEFT(\_E), RIGHT(\_E)

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| RIGHT       |                     |
| RIGHTP      |                     |

### Setting data

### Descriptions, ranges, and data types

| Operand | Description                                                                                                           | Range      | Data type            | Data type (label) |
|---------|-----------------------------------------------------------------------------------------------------------------------|------------|----------------------|-------------------|
| (s)     | Character string or the start device containing the string                                                            | —          | String               | ANYSTRING_SINGLE  |
| (d)     | Start device for storing (n) characters of string extracted from the right of the data in the device specified by (s) | —          | String               | ANYSTRING_SINGLE  |
| (n)     | Number of characters to be extracted                                                                                  | 1 to 16383 | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                                                                                   | —          | Bit                  | BOOL              |
| ENO     | Execution result                                                                                                      | —          | Bit                  | BOOL              |

### Applicable devices

| (s)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | ○  | —      |
| (d)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                                | ○   | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions extract (n) characters of data from the right of the string data (the end of the string) stored in the device number specified by (s) and later, and store the extracted data in the device number specified by (d) and later.

**Ex.**

When (n)=5

(1) ASCII code (5th character)

- The NULL code (00H) indicating the end of a string is automatically added to the end of the string data.
- When the number of characters in the device specified by (n) is 0, NULL code (00H) is stored in the device specified by (n).

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (00H) set in the assignment range of the relevant device/label for the device number specified by (s) and later.                                                                                                                                                                                                                              |
| 3285H            | An out-of-range value is set to (s). <ul style="list-style-type: none"> <li>The number of characters of the string in the device specified by (s) exceeds 16383.</li> <li>The number of characters of the string in the device specified by (s) is 0.</li> </ul> The number of characters in the device specify by (n) exceeds that in the device specified by (s). |
| 3286H            | The entire string that was extracted in the assignment range of the relevant device/label for the device number specified by (d) and later cannot be stored.                                                                                                                                                                                                        |

## Extracting string data from the left

### LEFT(P)

These instructions extract (n) characters of data from the left of the string data, and store the extracted data in the device number specified by (d) and later.

| Ladder               | ST <sup>*1</sup>      |
|----------------------|-----------------------|
|                      | ENO:=LEFTP(EN,s,n,d); |
| FBD/LD <sup>*1</sup> |                       |
|                      |                       |

\*1 The LEFT instruction does not support the ST and FBD/LD. Use the standard function, LEFT.

## Processing details

- These instructions extract (n) characters of data from the left of the string data (the start of the string) stored in the device number specified by (s) and later, and store the extracted data in the device number specified by (d) and later.

**Ex.**

When (n)=7

(1) ASCII code (7th character)

- The NULL code (00H) indicating the end of a string is automatically added to the end of the string data.
- When the number of characters in the device specified by (n) is 0, NULL code (00H) is stored in the device specified by (n).

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                         |

## Processing details

- These instructions extract the data by the number of characters specify by (s2)+1 from the location specified by (s2) in the string data stored in the device number specified by (s1) and later, and store the extracted data in the device number specified by (d) and later.

(1) 5th character position (s2)

(2) ASCII code for 5th character (s2)+1

- The NULL code (00H) indicating the end of a string is automatically added to the end of the string data.
- If the number of characters in the device specified by (s2)+1 is 0, no processing is performed.
- When the number of characters of the data in the device specified by (s2)+1 is -1, the data till the last character data in the device specified by (s1) is stored in the device specified by (d) and later.

(1) 5th character position (s2)

## Processing details

- These instructions read data by the number of characters stored in the device specified by (s2)+1 from the string data stored in the device number specified by (s1) and later, and store the read data at the location in the device specified by (s2) and later in the string stored in the device number specified by (d) and later.

- The NULL code (00H) indicating the end of a string is automatically added to the end of the string data.
- If the number of characters in the device specified by (s2)+1 is 0, no processing is performed.
- If the number of characters in the device specified by (s2)+1 exceeds the last character of the string data in the device specified by (d), the data is stored up to the last character.

- When the number of characters of the data in the device specified by (s2)+1 is -1, the data till the last character data in the device specified by (s1) is stored in the device specified by (d) and later.

## Processing details

- These instructions search the string data stored in the device number specified by (s2) and later starting from the (s3)th character from the left for the string data stored in the device number specified by (s1) and later, and store the search result in the device specified by (d). The search result stored shows the number of characters from the start character of the string data in the device specified by (s2).

- (1) Search start position (s3): 3rd character  
 (2) 5th character from the beginning of the data

- If no string data is matching, 0 is stored in the device specified by (d).

## Processing details

- These instructions insert the string data in the device specified by (s1) to the (s2)th character (insertion position) from the start of the string data in the device specified by (d).

- If the string after insertion in the device specified by (s1)+(d) is even, the NULL code (00H) is stored in the device (1 word) next to the last one containing the string.
- If the string after insertion in the device specified by (s1)+(d) is odd, the NULL code (00H) is stored in the last device (upper 8 bits) of the string.
- When the number of characters in the device specified by (d) plus 1 is specified in (s2), the string in the device specified by (s1) is concatenated to the end of the string in the device specified by (d).

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Processing details

- These instructions delete (n) characters starting from the position (deletion start position) specified by the (s)th character from the start of the string data in the device specified by (d).

- If the string after deletion in the device specified by (d) is even, the NULL code (00H) is stored in the device (1 word) next to the last one containing the string.
- If the string after deletion in the device specified by (d) is odd, the NULL code (00H) is stored in the last device (upper 8 bits) of the string.
- The string following the deleted one is shifted by (n) characters to the right, and the NULL code (00H) is stored in the device that has been emptied.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

# 17 REAL VALUE PROCESSING

## 17.1 Floating-point Instruction

### Comparing single-precision real numbers

#### LDE□, ANDE□, ORE□

These instructions perform a comparison operation of a single-precision real number. (Devices are used as a normally open contact.)

| Ladder                                                                                                                                                   | ST                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
|  <p>(□ is replaced by E=, E&lt;&gt;, E&gt;, E&lt;=, E&lt;, E&gt;=.)</p> | <pre>ENO:=LDE_□(EN,s1,s2); ENO:=ANDE_□(EN,s1,s2); ENO:=ORE_□(EN,s1,s2);</pre> <p>(□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)*1</p> |

#### FBD/LD

(□ is replaced by a combination of LDE\_, ANDE\_, or ORE\_ and EQ, NE, GT, LE, LT, or GE.)\*1

\*1 EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

#### ■Execution condition

| Instruction       | Execution condition |
|-------------------|---------------------|
| LDE□, ANDE□, ORE□ | Every scan          |

#### Setting data

#### ■Description, range, data type

| Operand | Description                                                             | Range                               | Data type                    | Data type (label) |

## Processing details

- These instructions perform a comparison operation between the single-precision real number in the device specified by (s1) and the single-precision real number in the device specified by (s2). (Devices are used as a normally open contact.)
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result                             |
|-------------------------------------|-----------|------------------------------------|
| E=, EQ                              | (s1)=(s2) | Continuity state (ENO is on.)      |
| E<>, NE                             | (s1)≠(s2) |                                    |
| E>, GT                              | (s1)>(s2) |                                    |
| E<=, LE                             | (s1)≤(s2) |                                    |
| E<, LT                              | (s1)<(s2) |                                    |
| E>=, GE                             | (s1)≥(s2) |                                    |
| E=, EQ                              | (s1)≠(s2) | Non-continuity state (ENO is off.) |
| E<>, NE                             | (s1)=(s2) |                                    |
| E>, GT                              | (s1)≤(s2) |                                    |
| E<=, LE                             | (s1)>(s2) |                                    |
| E<, LT                              | (s1)≥(s2) |                                    |
| E>=, GE                             | (s1)<(s2) |                                    |

- If the data in the device specified by (s1) or (s2) is out of the range of setting data, the operation result will be non-continuity (ENO OFF).
- If the LDE\_□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the ORE\_□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

📖 Page 40 Precautions

## Operation error

There is no operation error.

### Point

Note that two values may not be equal due to an error when the E= instruction is used.

(1) Two values may not be equal.

# Comparing double-precision real numbers

## LDED□, ANDED□, ORED□

These instructions perform a comparison operation of a double-precision real number. (Devices are used as a normally open contact.)

| Ladder   | ST                                                                                                                                                    |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

(□ is replaced by ED=, ED<>, ED>, ED<=, ED<, ED>=.)

## FBD/LD

(□ is replaced by a combination of LDED\_, ANDED\_, or ORED\_ and EQ, NE, GT, LE, LT, or GE.)\*1

\*1 EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

## Execution condition

| Instruction          | Execution condition |
|----------------------|---------------------|
| LDED□, ANDED□, ORED□ | Every scan          |

## Setting data

## Description, range, data type

| Operand | Description                                                             | Range                                 | Data type                    | Data type (label) |

## Processing details

- These instructions perform a comparison operation between the double-precision real number in the device specified by (s1) and the double-precision real number in the device specified by (s2). (Devices are used as a normally open contact.)
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result                             |
|-------------------------------------|-----------|------------------------------------|
| ED=, EQ                             | (s1)=(s2) | Continuity state (ENO is on.)      |
| ED<>, NE                            | (s1)≠(s2) |                                    |
| ED>, GT                             | (s1)>(s2) |                                    |
| ED<=, LE                            | (s1)≤(s2) |                                    |
| ED<, LT                             | (s1)<(s2) |                                    |
| ED>=, GE                            | (s1)≥(s2) |                                    |
| ED=, EQ                             | (s1)≠(s2) | Non-continuity state (ENO is off.) |
| ED<>, NE                            | (s1)=(s2) |                                    |
| ED>, GT                             | (s1)≤(s2) |                                    |
| ED<=, LE                            | (s1)>(s2) |                                    |
| ED<, LT                             | (s1)≥(s2) |                                    |
| ED>=, GE                            | (s1)<(s2) |                                    |

- If the data in the device specified by (s1) or (s2) is out of the range of setting data, the operation result will be non-continuity (ENO OFF).
- If the LDED\_□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the ORED\_□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

 Page 40 Precautions

## Operation error

There is no operation error.

## Precautions

The maximum number of digits of a real number which can be input using the engineering tool is 15, and therefore these instructions cannot perform comparison with a real number consisting of 16 or more effective digits. When these instructions are used to determine the match or mismatch with a real number consisting of 16 or more effective digits, the instructions need to compare the size with the approximate values before and after the real number to be compared.

**Ex.**

To determine the match between E1.234567890123456+10 (16 effective digits) and a double-precision real number

(1) Whether data in D0 to D3 are within this range is checked. (The boundary values are not included.)

**Ex.**

To determine the mismatch between E1.234567890123456+10 (16 effective digits) and a double-precision real number

(1) Whether data in D0 to D3 are within this range is checked. (The boundary values are included.)

# Adding single-precision real numbers

## E+(P) [when two operands are set]

These instructions add single-precision real numbers.

| Ladder                                                            | ST                                                                |
|-------------------------------------------------------------------|-------------------------------------------------------------------|
|                                                                   | Not supported<br>(  Page 819 E+(P) [when three operands are set]) |
| FBD/LD                                                            |                                                                   |
| Not supported<br>(  Page 819 E+(P) [when three operands are set]) |                                                                   |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| E+          |                     |
| E+P         |                     |

### Setting data

### Description, range, data type

| Operand | Description                                                                   | Range                              | Data type                    | Data type (label) |
|---------|-------------------------------------------------------------------------------|------------------------------------|------------------------------|-------------------|
| (s)     | Second addend data or the start device where the second addend data is stored | $0, 2^{-126} \leq  (s)  < 2^{128}$ | Single-precision real number | ANYREAL_32        |
| (d)     | Start device where the first addend data is stored                            | $0, 2^{-126} \leq  (d)  < 2^{128}$ | Single-precision real number | ANYREAL_32        |

### Applicable devices

| Operand | Bit                              |      | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□□, J□□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                                | —    | ○                                     | ○          | ○ | ○           | ○  | ○                      | —        | ○ | —  | —      |
| (d)     | —                                | —    | ○                                     | ○          | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions add the single-precision real number in the device specified by (s) to the single-precision real number in the device specified by (d), and store the result in the device specified by (d).

- Value  $0$  or  $2^{-126} \leq |\text{specified value (stored value)}| < 2^{128}$  can be specified or stored in the devices specified by (s) and (d).
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                                  |
|                  | The value input to (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                                  |
| 3283H            | The data in the device specified by (d) exceeds the following range. (An overflow has occurred.)<br>$ {(d)}  < 2^{128}$ |

## E+(P) [when three operands are set]

These instructions add single-precision real numbers.

### Processing details

- These instructions subtract the single-precision real number in the device specified by (s) from the single-precision real number in the device specified by (d), and store the result in the device specified by (d).

- Value  $0$  or  $2^{-126} \leq |\text{specified value (stored value)}| < 2^{128}$  can be specified or stored in the devices specified by (s) and (d).
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                                  |
|                  | The value input to (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                                  |
| 3283H            | The data in the device specified by (d) exceeds the following range. (An overflow has occurred.)<br>$ {(d)}  < 2^{128}$ |

## E-(P) [when three operands are set]

These instructions perform subtraction between single-precision real numbers.

## Processing details

- These instructions subtract the double-precision real number in the device specified by (s) from the double-precision real number in the device specified by (d), and store the result in the device specified by (d).

- Value  $0$  or  $2^{-1022} \leq |\text{specified value (stored value)}| < 2^{1024}$  can be specified or stored in the devices specified by (s) and (d).
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                                                              |

## Processing details

- These instructions multiply the double-precision real number in the device specified by (s1) by the double-precision real number in the device specified by (s2), and store the multiplication result in the device specified by (d).

- Value 0 or  $2^{-1022} \leq |\text{specified value (stored value)}| < 2^{1024}$  can be specified or stored in the devices specified by (s1), (s2), and (d).
- If the operation result is -0 or an underflow occurs, the operation result turns out to 0.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

☞ Page 40 Precautions

## Operation error

## Processing details

- These instructions convert the 32-bit signed binary data in the device specified by (s) to a single-precision real number, and stores the real number in the device specified by (d).

- A single-precision real number is processed in 32-bit single precision, and therefore the effective number of digits is 24 bits when it is represented in binary and is about 7 digits when represented in decimal. For this reason, if the integer value exceeds the range from -16777216 to 16777215 (24-bit binary value), an error occurs in the converted value. The operation result is an integer value in which the 25th bit from upper bits is rounded off.

- (1) Rounded down.  
(2) Rounded off.

## Operation error

There is no operation error.

# Converting 32-bit unsigned binary data to single-precision real number

## Processing details

- These instructions convert the string stored in the device number specified by (s) and later to single-precision real number data, and store the converted real number in the device specified by (d).
- The specified string can be converted to a single-precision real number in either decimal point or exponential format.

- "20H" (space) that exists in the middle of the data is ignored.
- The string can consist of up to 24 characters. "20H" (space) and "30H" (0) are counted as one character as well.

### Decimal point format

- When the string in the device specified by (s) is in decimal point format, conversion is performed as shown below.

[1][0][7][8][1][2]

(1) Single-precision real number

- The string in the device specified by (s) to be converted to a single-precision real number is converted by assuming that the six digits excluding the sign, decimal point, and exponent are effective and the seventh and subsequent digits are discarded.

[1][0][3][0][1][5][6][1][2]

(1)

(1) Rounded down.

(2) Single-precision real number

- If 2BH(+) is specified for the sign or the sign is omitted in decimal point format, the converted single-precision real number is treated as a positive value. If 2DH(-) is specified for the sign, it is treated as a negative value.
- If 20H (space) or 30H (0) exists between digits excluding the first 0 in the string in the device specified by (s), the instruction performs conversion by ignoring 20H and 30H.

(1) Ignored.

(2) Single-precision real number

## ■ Exponential format

- When the string in the device specified by (s) is in exponential format, conversion is performed as shown below.

(1) Single-precision real number

- The string in the device specified by (s) to be converted to a single-precision real number is converted by assuming that the six digits excluding the sign, decimal point, and exponent are effective and the seventh and subsequent digits are discarded.

(1) Rounded down.

(2) Single-precision real number

- If 2BH(+) is specified for the sign or the sign is omitted in exponential format, the converted single-precision real number is treated as a positive value. If 2DH(-) is specified for the sign in the exponent, it is treated as a negative value.
- If 20H (space) or 30H (0) exists between digits excluding the first 0 in the string in the device specified by (s), the instruction performs conversion by ignoring 20H and 30H.
- If 30H (0) exists between "E" and a numerical value in the string in exponential format, the instruction performs conversion by ignoring 30H.

(1) Ignored.

(2) Single-precision real number

- When "20H" (space) is contained in string, "20H" is ignored during conversion.
- The string can consist of up to 24 characters. "20H" (space) and "30H" (0) in a string are counted as one character as well.

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# Converting BCD format data to single-precision real number

## EREXP(P)

These instructions convert BCD floating point format data to single-precision real number data in accordance with the specified number of digits in the decimal part.

| Ladder | ST                                                          |

## Processing details

- These instructions convert the BCD floating-point format data stored in the device specified by (s1) and later to single-precision real number data in accordance with the number of decimal places stored in the device specified by (s2), and store the converted data in the device number specified by (d) and later.

(s1): Sign (Positive: 0, Negative: 1)  
 (s1)+1, (s1)+2: BCD (7 digits)  
 (s1)+3: Sign of exponent (Positive: 0, Negative: 1)  
 (s1)+4: BCD exponent (0 to 38)  
 (s2): Number of digits in the decimal part (0 to 7)  
 (d)+1, (d): Single-precision real number

- For the sign in (s1) and exponent sign in (s1)+3, 0 is set for positive and 1 is set for negative.
- A value of 0 to 38 can be set for the BCD exponent in (s1)+4.
- A value of 0 to 7 can be set for the number of decimal digits in the device specified by (s2).

### Ex.

When 6 is specified in (s2)

## Operation error

### Processing details

- These instructions invert the sign of the double-precision real number data in the device specified by (d) and store the inverted data in the device specified by (d).

- The instructions are used to invert positive and negative signs.

### Operation error

| Error code (SD0) | Description                                                                            |
|------------------|----------------------------------------------------------------------------------------|
| 3282H            | The value input to (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |

# Transferring single-precision real number

## EMOV(P)

These instructions transfer single-precision real number data to the specified device.

| Ladder | ST                                       |
|--------|------------------------------------------|

### Processing details

- These instructions calculate the tangent of the angle specified by (s), and store the operation result in the device specified by (d).

- Set the angle data in radians (angle×π÷180).
- If the operation result is -0 or an underflow occurs, the operation result turns out to 0.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

### Precautions

If the angle specified by (s) is  $\pi/2$  radian or  $(3/2)\pi$  radian, no operation error will be issued because of the truncation error in the radian value.

### Operation error

| Error code (SD0) | Description                                                                            |
|------------------|----------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |

For the angle↔radian conversion, refer to the RAD(P) and DEG(P) instructions.

## Processing details

- These instructions calculate the sine of the angle specified by (s), and store the operation result in the device specified by (d).

- Set the angle data in radians ( $\text{angle} \times \pi \div 180$ ).
- If the operation result is -0 or an underflow occurs, the operation result turns out to 0.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                            |
|------------------|----------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |

### Point

For the angle↔radian conversion, refer to the RADD(P) and DEGD(P) instructions.

Page 906 RADD(P)

Page 908 DEGD(P)

# Calculating the cosine of double-precision real number

## COSD(P)

These instructions calculate the cosine of the angle specified by a double-precision real number.

| Ladder                                                                            | ST*1                |
|-----------------------------------------------------------------------------------|---------------------|
|  | ENO:=COSDP(EN,s,d); |

## FBD/LD\*1

\*1 The COSD instruction does not support the ST and FBD/LD. Use the standard function, COS.

## Processing details

- These instructions calculate the angle based on the cosine data in the device specified by (s), and store the operation result in the device number specified by (d).

- The cosine data in the device specified by (s) can be set in the range from -1.0 to 1.0.
- The angle (operation result) is stored in radians in the device specified by (d).
- If the operation result is -0 or an underflow occurs, the operation result turns out to 0.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

☞ Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                            |
|------------------|----------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |
| 3285H            | The value in the device specified by (s) is out of the range, -1.0 to 1.0.             |

### Point

For the angle↔radian conversion, refer to the RADD(P) and DEGD(P) instructions.

☞ Page 906 RADD(P)

☞ Page 908 DEGD(P)

# Calculating the arc tangent of double-precision real number

## ATAND(P)

These instructions calculate the angle from the tangent specified by a double-precision real number.

| Ladder | ST*1                 |
|--------|----------------------|
|        | ENO:=ATANDP(EN,s,d); |

| FBD/LD*1 |
|----------|
|          |

\*1 The ATAND instruction does not support the ST and FBD/LD. Use the standard function, ATAN.

Page 1328 ATAN(\_E)

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| ATAND       |                     |
| ATANDP      |                     |

## Processing details

- These instructions calculate the sine of the angle specified by (s), and store the sign of the operation result in the device specified by (d) and the operation result in the devices specified by (d)+1 and (d)+2.

SIN (s) =

(d): Sign

(d)+1: Integral part

(d)+2: Decimal part

- For the value to be specified in (s), set a value from 0 to 360° (in the DEG. unit) as a BCD value.
- For the sign of the operation result to be stored in the device specified by (d), 0 is stored when the operation result is positive and 1 is stored when the operation result is negative.
- The operation result to be stored in the devices specified by (d)+1 and (d)+2 is a BCD value in the range from -1.000 to 1.000.
- The operation result is a value whose 5th decimal place is rounded off.

## Operation error

| Error code<br>(SD0) | Description                                                                                                                                                                              |

## Processing details

- These instructions calculate the tangent of the angle specified by (s), and store the sign of the operation result in the device specified by (d) and the operation result in the devices specified by (d)+1 and (d)+2.

$$\text{TAN (s)} = \boxed{\text{(d)}} \boxed{\text{(d)+1}} . \boxed{\text{(d)+2}}$$

(d): Sign

(d)+1: Integral part

(d)+2: Decimal part

- For the value to be specified in (s), set a value from 0 to 360° (in the DEG. unit) as a BCD value.
- For the sign of the operation result to be stored in the device specified by (d), 0 is stored when the operation result is positive and 1 is stored when the operation result is negative.
- The operation result to be stored in the devices specified by (d)+1 and (d)+2 is a BCD value in the range from -57.2901 to 57.2903.
- The operation result is a value whose 5th decimal place is rounded off.

## Processing details

- These instructions convert the unit of the measure of angle from the degree specified by (s) to the radian, and store the angle in radians in the device number specified by (d).

- Unit conversion from the degree to the radian is performed as follows.

$$\text{Radian} = \text{Degree} \times \frac{\pi}{180}$$

- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

## Processing details

- These instructions calculate the square root of the value specified by (s), and store the operation result in the device specified by (d).

- The value specified by (s) must be positive. (No negative value can be calculated.)
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

📖 Page 40 Precautions

## Processing details

- These instructions calculate the exponent of the value specified by (s), and store the operation result in the device specified by (d).

- Exponent operation is performed with the base (e) set to "2.71828".
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

 Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                        |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ (\text{d})  < 2^{128}$ |

### Point

- The EXP(P) instruction performs operation using the natural logarithm. To determine a value using the common logarithm, determine a value by dividing the common logarithm value by 0.43429 and specify it in the device specified by (s).

$$10^X = e^{\frac{X}{0.43429}}$$

# Calculating the exponent of double-precision real number

## EXPDP(P)

These instructions calculate the exponent of the value specified by a double-precision real number.

| Ladder | ST*1                |
|--------|---------------------|
|        | ENO:=EXPDP(EN,s,d); |

| FBD/LD*1 |
|----------|
|          |

\*1 The EXPDP instruction does not support the ST and FBD/LD. Use the standard function, EXP.

Page 1322 EXP(\_E)

## Execution condition

| Instruction | Execution condition |

## Processing details

- These instructions calculate the logarithm using natural logarithm (e) of the value specified by (s), and store the operation result in the device specified by (d).

- Input a positive value only. (No negative value can be calculated.)
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

 Page 40 Precautions

## Operation error

| Error code (SD0) | Description                                                                                                                                                         |

## Processing details

- These instructions calculate the logarithm using natural logarithm (e) of the value specified by (s), and store the operation result in the device specified by (d).

- Input a positive value only. (No negative value can be calculated.)
- If the operation result is -0 or an underflow occurs, the operation result turns out to 0.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

## Operation error

## Processing details

- These instructions calculate the square root of the BCD 4-digit data specified by (s), and store the operation result in the device specified by (d).

$$\sqrt{\boxed{(s)}} = \boxed{(d)}.\boxed{(d)+1}$$

(d): Integral part

(d)+1: Decimal part

- The value to be specified in (s) is a BCD value with a maximum of 4 digits (0 to 9999).
- A BCD value from 0 to 9999.9999 is stored as the operation result in the device specified by (d).
- The operation result is a value whose 5th decimal place is rounded down.

## Operation error

| Error code (SD0) | Description                                                 |
|------------------|-------------------------------------------------------------|
| 3285H            | The data in the device specified by (s) is not a BCD value. |

# Calculating the square root of BCD 8-digit data

## BDSQRT(P)

These instructions calculate the square root of the value specified by a BCD 8-digit data.

| Ladder | ST                                                   |

## Processing details

- These instructions raises the single-precision real number specified by (s1) to the power of the single-precision real number specified by (s2), and store the operation result in the device specified by (d).

- The values that can be specified by (s1) and (s2) and the value that can be stored are  $0, 2^{-126} \leq |\text{setting value (stored value)}| < 2^{128}$ .
- If the operation result is -0 or an underflow occurs, the operation result turns out to 0.
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

## Processing details

- These instructions search for the maximum value in the (n) points of single-precision real number block data in the device starting from the one specified by (s), and store the maximum value in the device specified by (d). The instructions store the location of the first maximum value by the number of points from (s) in the device specified by (d)+2 and the number of maximum values in the device specified by (d)+3.
- The start of the block data in the device specified by (s) is counted as the 1st point when the search result (location) is counted.

(d), (d)+1: Maximum value  
 (d)+2: Location  
 (d)+3: Number of maximum values

- When (n) is 0, the processing is not performed.

## Operation error

## Processing details

- These instructions search for the minimum value in the (n) points of double-precision real number block data in the device starting from the one specified by (s), and store the maximum value in the device specified by (d). The instructions store the location of the first minimum value by the number of points from (s) in the device specified by (d)+4 and the number of minimum values in the device specified by (d)+5.
- The start of the block data in the device specified by (s) is counted as the 1st point when the search result (location) is counted.

(d), (d)+1, (d)+2, (d)+3: Minimum value  
 (d)+4: Location  
 (d)+5: Number of minimum values

- When (n) is 0, the processing is not performed.

## Operation error

| (d)     | ○                                | ○   | ○                                     | ○         | ○ | —           | —  | ○                      | —        | — | —  | — |        |

#### Processing details

These instructions generate a random number between 0 and 32767, and store the random number in the device specified by (d). The RND(P) instruction generates random numbers according to a certain calculation expression. The calculation expression uses the previous calculation result as a coefficient.

#### Operation error

There is no operation error.

## Changing random sequence

### SRND(P)

These instructions change the random number sequence according to the content of the 16-bit binary data stored in the specified device.

| Ladder | ST                                            |
|--------|-----------------------------------------------|
|        | <pre>ENO:=SRND(EN,s); ENO:=SRNDP(EN,s);</pre> |

| FBD/LD |
|--------|
|        |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| SRND        |                     |
| SRNDP       |                     |

### Setting data

### ■Description, range, data type

| Operand | Description                 | Range           | Data type            | Data type (label) |
|---------|-----------------------------|-----------------|----------------------|-------------------|
| (s)     | Random number sequence data | -32768 to 32767 | 16-bit signed binary | ANY16             |
| EN      | Execution condition         | —               | Bit                  | BOOL              |
| ENO     | Execution result            | —               | Bit                  | BOOL              |

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |            | Z | Double word |    | Indirect specification | Constant |   |    | Others |

| (s)     | ○                                | ○   | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |

### Processing details

These instructions change the random number sequence according to the content of the 16-bit binary data stored in the device specified by (s). The SRND(P) instruction can change the random number calculation pattern.

### Operation error

There is no operation error.

# 19 DEVICE OPERATION

## 19.1 Index Register Instructions

### Saving all data of the index register

#### ZPUSH(P)

These instructions save the content of the index register to the specified area.

| Ladder                                                                            | ST                                       |
|-----------------------------------------------------------------------------------|------------------------------------------|
|  | ENO:=ZPUSH(EN,d);<br>ENO:=ZPUSHHP(EN,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

#### ■Execution condition

| Instruction | Execution condition                                                                 |
|-------------|-------------------------------------------------------------------------------------|
| ZPUSH       |  |
| ZPUSHHP     |  |

#### Setting data

#### ■Description, range, data type

| Operand | Description                                            | Range | Data type            | Data type (label)   |
|---------|--------------------------------------------------------|-------|----------------------|---------------------|
| (d)     | Start device to which the index register will be saved | —     | 16-bit signed binary | ANY16 <sup>*1</sup> |
| EN      | Execution condition                                    | —     | Bit                  | BOOL                |
| ENO     | Execution result                                       | —     | Bit                  | BOOL                |

\*1 When specifying data with a label, define the array so that an area required for operation can be secured, and specify the array label element.

#### ■Applicable devices

| Operand | Bit                              |     | Word                                  |           |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|-----------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (d)     | —                                | —   | ○                                     | —         | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions save the contents of the index register, long index register, local index register, and local long index register in the device specified by (d) or the array label element and later. The local index register and local long index register to be saved are the local index register and local long index register of the program that executed the ZPUSH instruction.
- When the content of the index register is saved, the number of saves (d) is incremented by 1.
- Regardless of the number of points assigned
- to the index register, long index register, local index register and local long index register, 48 words of data are saved.
- The ZPOP(P) instructions can be used to restore data. The ZPUSH(P) and ZPOP(P) instructions are used in pairs and can be nested to be used as a stack.

### Page 947 ZPOP(P)

- A nesting structure can be created by specifying the area specified by (d) of the ZPUSH(P) instruction in (d) of the ZPUSH(P) instruction again. The number of saves (d) is incremented by 1 every time the ZPUSH(P) instruction is executed.
- When another area is specified in (d) of the ZPUSH(P) instruction in the nesting structure, the content of the index register is saved to the specified another area.
- In the nesting structure, every time the ZPUSH(P) instruction is executed, saved data is added. Therefore, secure in advance the areas necessary for the number of times the instruction is executed.

**Ex.**

When the local setting of the index register setting is set as follows in the engineering tool, the following figure shows the configuration of the areas used after (d).

[CPU Parameter] ⇒ [Memory/Device Setting] ⇒ [Index Register Setting]

| Item          |                          |                                | Set value |
|---------------|--------------------------|--------------------------------|-----------|
| Local setting | Number of points setting | Local Index register (Z)       | 5 points  |
|               |                          | Local long index register (LZ) | 5 points  |
|               | Start                    | Index register (Z)             | 10        |
|               |                          | Long index register (LZ)       | 0         |

(1) Save the local index register for 5 points from Z10.

(2) Save the local long index register for 5 points from LZ0.

## Operation error

| Error code (SD0) | Description                           |
|------------------|---------------------------------------|
| 3285H            | The number of saves in (d)+0 is FFFF. |

## Returning all data of the index register

### ZPOP(P)

These instructions read the data, which has been saved to the specified area, into the index register.

| Ladder                                                                            | ST                                    |

\*1 When specifying data with a label, define the array so that an area required for operation can be secured, and specify the array label element.

### Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (d)     | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions read the data, which has been saved to the device specified by (d) or the array label element and later, into the index register, long index register, local index register, and local long index register.
- When the content of the index register is read, the number of saves (d) is decremented by 1.
- The local index register and local long index register to be restored are the local index register and local long index register of the program that executed the ZPOP instruction.
- Refer to the following for the configuration of the areas used after (d).

📖 Page 944 ZPUSH(P)

### Operation error

| Error code (SD0) | Description                        |
|------------------|------------------------------------|
| 3285H            | The number of saves in (d)+0 is 0. |

# Saving the selected data of the index register and long index register

## ZPUSH(P)

These instruction save the contents of the index register and long index register to the specified area.

| Ladder | ST                                             |
|--------|------------------------------------------------|
|        | ENO:=ZPUSH_2(EN,s,d);<br>ENO:=ZPUSH_2(EN,s,d); |

## FBD/LD

(□ is replaced by ZPUSH\_2 or ZPUSH\_2.)

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| ZPUSH       |                     |
| ZPUSHP      |                     |

## Setting data

## Descriptions, ranges, and data types

| Operand | Description                                                                    | Range  | Data type              | Data type (label)   |
|---------|--------------------------------------------------------------------------------|--------|------------------------|---------------------|
| (s)     | Type of the index register and long index register to be saved                 | 1 to 3 | 16-bit unsigned binary | ANY16               |
| (d)     | Start device to which the index register and long index register will be saved | —      | 16-bit signed binary   | ANY16 <sup>*1</sup> |
| EN      | Execution condition                                                            | —      | Bit                    | BOOL                |
| ENO     | Execution result                                                               | —      | Bit                    | BOOL                |

<sup>\*1</sup> When specifying data with a label, define the array so that an area required for operation can be secured, and specify the array label element.

## Applicable devices

| Operand | Bit                              |      | Word                                  |                 |   | Double word |    | Indirect specification | Constant |   |    | Others |

|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□\□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□     | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                                | —    | ○                                     | ○ <sup>*1</sup> | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                                | —    | ○                                     | —               | — | —           | —  | ○                      | —        | — | —  | —      |

<sup>\*1</sup> Only U3E□\G□ can be used.

## Processing details

- These instructions save the index register, long index register, local index register, and local long index register to be saved in the device specified by (d) or the array label element and later.
- When the contents of the index register, long index register, local index register and local long index register are saved, the number of saves (d) is incremented by 1.
- The local index register and local long index register to be saved are the local index register and local long index register of the program that executed the ZPUSH instruction.
- The type of the index register, long index register, local index register and local long index register to be saved are stored to the end of the saved data.
- The following table lists the values specified by (s), and the index register, long index register, local index register, and local long index register to be saved.

| Value of (s) | Z and LZ saved          |
|--------------|-------------------------|
| 1            | Total range of Z and LZ |
| 2            | Total range of Z        |
| 3            | Total range of LZ       |

- The ZPOP(P) instructions (restoring the selected data of the index register and long index register) are used to restore data. The ZPUSH(P) and ZPOP(P) instructions are used in pairs and can be nested to be used as a stack.

### Page 952 ZPOP(P)

- A nesting structure can be created by specifying the area specified by (d) of the ZPUSH(P) instruction in (d) of the ZPUSH(P) instruction again. The number of saves (d) is incremented by 1 every time the ZPUSH(P) instruction is executed.
- When another area is specified in (d) of the ZPUSH(P) instruction in the nesting structure, the content of the index register or long index register is saved to the specified another area.
- In the nesting structure, every time the ZPUSH(P) instruction is executed, saved data is added. Therefore, check the numbers of points assigned to the index register and long index register according to SD300 and SD302, and secure in advance the areas necessary for the number of times the instruction is executed.

**Ex.**

When the local setting of the index register setting is set as follows in the engineering tool, the following figure shows the configuration of the areas used after (d).

[CPU Parameter] ⇒ [Memory/Device Setting] ⇒ [Index Register Setting]

| Item          |                          |                                | Set value |
|---------------|--------------------------|--------------------------------|-----------|
| Local setting | Number of points setting | Local Index register (Z)       | 5 points  |
|               |                          | Local long index register (LZ) | 5 points  |
|               | Start                    | Index register (Z)             | 10        |
|               |                          | Long index register (LZ)       | 0         |

(1) Save the local index register for 5 points from Z10.

(2) Save the local long index register for 5 points from LZ0.

## Precautions

(d)+1 and (d)+2 for the ZPUSH(P) instructions are used for the system. Do not change the values.

The Z and LZ save types stored in the area specified by (d) and later are also used for the system. Do not change the values.

Changing the values may cause malfunction of the module.

## Operation error

| (s)     | ○                                | —   | ○                                     | ○ <sup>*1</sup> | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                                | —   | ○                                     | —               | — | —           | —  | ○                      | —        | — | —  | —      |

\*1 Only U3E□\G□ can be used.

## Processing details

- These instructions read the data, which has been saved to the device specified by (d) or the array label element and later, into the index register, long index register, local index register, and local long index register.
- When the data saved to the index register and long index register is read, the number of saves (d) is decremented by 1.
- The local index register and local long index register to be restored are the local index register and local long index register of the program that executed the ZPOP instruction.
- The date data in the device specified by (s) is regarded as dummy data and ignored.
- Refer to the following for the configuration of the areas used after (d).

Page 948 ZPUSH(P)

## Precautions

(d)+1 and (d)+2 are used for the system. Do not change the values.

The Z and LZ save types stored in the area specified by (d) and later are also used for the system. Do not change the values.

Changing the values may cause malfunction of the module.

## Operation error

## Processing details

These instructions switch the block number of the file register used in the program to that stored in the device specified by (s). After the block number is changed, all file registers processed by the sequence program are those linked to the new block number.

## Precautions

If "Block No. Save/Recovery Setting" of the file register from the engineering tool is set to "Not Saved/Recovered", do not use this instruction to switch the file register block number in the interrupt program. If the block number is switched, the change may not be reflected immediately after returning from the interrupt program, and the block number may not be switched until the start of the next program.

For the restrictions of the file register, refer to the following.

☞ Page 59 Restrictions on using file registers

## Operation error

| Error code (SD0) | Description                                                     |
|------------------|-----------------------------------------------------------------|
| 2820H            | The specified file register does not exist.                     |
| 3285H            | The block number in the device specified by (s) does not exist. |

# 19.3 File Register Read/Write Instructions

## Reading 1-byte data from the file register

### ZRRDB(P)

These instructions read the data from the file register with the specified serial byte number.

| Ladder | ST                                          |
|--------|---------------------------------------------|
|        | ENO:=ZRRDB(EN,s,d);<br>ENO:=ZRRDBP(EN,s,d); |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| ZRRDB       |                     |
| ZRRDBP      |                     |

### Setting data

### Descriptions, ranges, and data types

| Operand | Description                                                        | Range           | Data type              | Data type (label) |
|---------|--------------------------------------------------------------------|-----------------|------------------------|-------------------|
| (s)     | Serial byte number of the file register to be read                 | 0 to 4294967295 | 32-bit unsigned binary | ANY32             |
| (d)     | Start number of the device for storing the data that has been read | —               | 16-bit signed binary   | ANY16             |

| (s)     | ○                                | ○   | ○                                     | ○           | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                                | ○   | ○                                     | ○           | ○ | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- Without recognizing block numbers, these instructions read the data from the file register with the serial byte number specified by (s), and store the data in the lower 8 bits of the device specified by (d). 00H is stored in the upper 8 bits of the device specified by (d).

- The following figure shows the file register numbers corresponding to serial byte numbers.

- (1) Data areas when an odd number is specified  
 (2) Data areas when an even number is specified

### Ex.

When 23560 is specified in (s), the data in the lower 8 bits of ZR11780 is read.

- (1) Specifying the read-target area

### Ex.

When 43257 is specified in (s), the data in the upper 8 bits of ZR21628 is read.

- (1) Specifying the read-target area

## Operation error

| Error code (SD0) | Description                                                       |
|------------------|-------------------------------------------------------------------|
| 2820H            | The specified device number (serial byte number) is out of range. |

# Writing 1-byte data to the file register

## ZRWRB(P)

These instructions write the data in the lower bits of the specified device to the file register with the specified serial byte number.

| Ladder | ST                                              |
|--------|-------------------------------------------------|
|        | ENO:=ZRWRB(EN,s1,s2);<br>ENO:=ZRWRBP(EN,s1,s2); |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| ZRWRB       |                     |
| ZRWRBP      |                     |

## Setting data

### Descriptions, ranges, and data types

| Operand | Description                                           | Range           | Data type              | Data type (label) |
|---------|-------------------------------------------------------|-----------------|------------------------|-------------------|
| (s1)    | Serial byte number of the file register to be written | 0 to 4294967295 | 32-bit unsigned binary | ANY32             |
| (s2)    | Device number where the write data is stored          | -32768 to 32767 | 16-bit signed binary   | ANY16             |
| EN      | Execution condition                                   | —               | Bit                    | BOOL              |
| ENO     | Execution result                                      | —               | Bit                    | BOOL              |

### Applicable devices

## Processing details

- Without recognizing block numbers, these instructions write the lower 8-bit data stored in the device specified by (s2) to the file register with the serial byte number specified by (s1). The instructions ignore upper 8-bit data in the device specified by (s2).

- The following figure shows the file register numbers corresponding to serial byte numbers.

- (1) Data areas when an odd number is specified  
 (2) Data areas when an even number is specified

### Ex.

When 12340 is specified in (s1), data is written to the lower 8 bits of ZR11170.

- (1) Specifying the write-target area  
 (2) Ignored

### Ex.

When 43257 is specified in (s1), data is written to the upper 8 bits of ZR21628.

- (1) Specifying the write-target area  
 (2) Ignored

## Operation error

| Error code (SD0) | Description                                                       |
|------------------|-------------------------------------------------------------------|
| 2820H            | The specified device number (serial byte number) is out of range. |

# 19.4 Indirect Address Read Instructions

19

## Reading the indirect address

### ADRSET(P)

These instructions read the indirect address of the specified device.

| Ladder | ST                                                                          |
|--------|-----------------------------------------------------------------------------|
|        | <pre>ENO:=ADRSET(EN,s,d); ENO:=ADRSETP(EN,s,d); ENO:=_ADRSET(EN,s,d);</pre> |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| ADRSET      |                     |
| ADRSETP     |                     |

### Setting data

### Descriptions, ranges, and data types

| Operand | Description                                                                                | Range | Data type            | Data type (label) |
|---------|--------------------------------------------------------------------------------------------|-------|----------------------|-------------------|

| (s)     | ○                                | —   | ○                                     | —          | — | ○           | —  | ○                      | —        | — | —  | —      |
| (d)     | ○                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions store the indirect address of the device specified by (s), and stores it in the device specified by (d). The address stored in the devices specified by (d)+0 and (d)+1 is used for indirect addressing of the device in the program.

(1) The address of W100 is stored in D100 and D101.

(2) The data (address of W100) stored in D100 and D101 is specified.

(3) "1234" is written to W100.

- Digit specification of bit device or bit specification of word device in (s) is not permitted
- For the indirect specification of devices, refer to the following.

📖 User's manual for the controller used

- Index specification of labels is not supported. When using a label by specifying it in (d), follow the method below.

| Label                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Global label specifying a device                  | <p>When using it as an indirect address, use the indirect specification of the device specified in the global label.</p> <p>■Example of ST</p> <pre>ADPSET(TRUE, intVar, gvAddr); // Read the intVar indirect address to gvAddr. INC(TRUE, @D0); // Use the indirect specification of device D0 specified for gvAddr.</pre>                                                                                                                                    |
| Automatic assignment global label/<br>local label | <p>Transfer the indirect address to the device and use the indirect specification of the transfer destination device.</p> <p>■Example of ST</p> <pre>ADPSET(TRUE, intVar, lvAddr); // Read the intVar indirect address to lvAddr. DMOV(TRUE, lvAddr, D0); // Transfer the indirect address, which has been read to lvAddr, to the device. INC(TRUE, @D0); // Use the indirect specification of the device to which the indirect address was transferred.</pre> |

## Operation error

There is no operation error.

# 20 TIMER, COUNTER

20

## 20.1 Special Counter Instructions

### Counting up or down the current value (1-phase input)

#### UDCNT1

This instruction updates the current value of the specified counter.

| Ladder | ST                       |
|--------|--------------------------|
|        | ENO:=UDCNT1(EN,s1,s2,d); |

| FBD/LD |
|--------|
|        |

#### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| UDCNT1      |                     |

#### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                                                                                                                                                                       | Range           | Data type            | Data type (label)                                     |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------|-------------------------------------------------------|
| (s1)    | (s1)+0: Count input number<br>(s1)+1: Count up/down flag<br>Off indicates count-up (counting up the current value).<br>On indicates count-down (counting down the current value). | —               | Bit                  | ANYBIT_ARRAY* <sup>1</sup><br>(Number of elements: 2) |
| (d)     | Number of the counter (device name) to be counted by the UDCNT1 instruction                                                                                                       | —               | Device name          | ANY16* <sup>2</sup>                                   |
| (s2)    | Set value                                                                                                                                                                         | -32768 to 32767 | 16-bit signed binary | ANY16                                                 |
| EN      | Execution condition                                                                                                                                                               | —               | Bit                  | BOOL                                                  |
| ENO     | Execution result                                                                                                                                                                  | —               | Bit                  | BOOL                                                  |

\*1 Only labels assigned to device (X) can be used.

\*2 Only labels assigned to device (C) can be used.

#### ■Applicable devices

| Operand | Bit                              |      | Word                                  |             |   |             | Double word |   | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|-------------|---|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□□ | Z | LT, LST, LC | LZ          |   |                        | K, H     | E | \$ |        |
| (s1)    | ○* <sup>1</sup>                  | —    | —                                     | —           | — | —           | —           | — | —                      | —        | — | —  | —      |
| (d)     | —                                | —    | ○* <sup>2</sup>                       | —           | — | —           | —           | — | —                      | —        | — | —  | —      |
| (s2)    | ○                                | ○    | ○                                     | ○           | ○ | —           | —           | ○ | ○                      | ○        | — | —  | —      |

\*1 Only X can be used. Note, however, that it can be used only within the range of the number of I/O points (the number of points that can access I/O modules).

\*2 Only C can be used.

## Processing details

- When the input specified by (s1) is turned on, this instruction updates the current value of the counter specified by (d).
- Counting up or down is determined by whether the input specified by (s1)+1 is on or off.
  - Off: Count-up (counting up the current value)
  - On: Count-down (counting down the current value)
- Count processing is performed as follows.
  - When the current value equals the value specified by (s2) during count-up, the contact of the counter specified by (d) is turned on. The current value is kept counting even when the contact of the counter is turned on.
  - When the current value equals "the set value - 1" during countdown, the contact of the counter specified by (d) is turned off.
  - The counter specified by (d) is a ring counter. Counting up the counter when the current value is 32767 proceeds to -32768. Similarly, counting down the counter when the current value is -32768 proceeds to 32767. The following figure shows the processing for counting the current value.

- (1) When counting up  
(2) When counting down

- The following figure shows the operation of count processing using the UDCNT1 instruction.

**Ex.**

Program which uses C0 (up/down counter) to count the number of times X40 turns off and on after X50 turns on

- (1) Current value of C0  
(2) Contact of C0

- When executed, the UDCNT1 instruction starts counting when the execution command turns on and stops counting when the command turns off. If the execution command is turned on again, the instruction resumes counting from the current value with which it stopped counting previously.
- The RST instruction is used to clear the current value of the counter specified by (d) and turn off the contact.

## Point

- The UDCNT1 instruction stores the device data of the argument in the work area of the controller, and performs the actual count operation using system interrupts. (The device data stored in the work area of the controller is cleared by turning off the execution command or setting it to STOP then RUN.) For this reason, the pulses that can be counted must have longer on/off time than the interval of the controller. The interrupt interval of the controller is 1ms.
- The set value cannot be changed during counting by the UDCNT1 instruction (while the execution command is on). To change the set value, turn off the execution command in advance.
- The counter specified by the UDCNT1 instruction cannot be used by any other instruction. If another instruction uses it, normal counting is disabled.
- The UDCNT1 instruction can be used a maximum of six times in all running programs. The seventh or subsequent UDCNT1 instruction, if issued, causes no processing.

## Operation error

There is no operation error.

# Counting up or down the current value (2-phase input)

20

## UDCNT2

This instruction updates the current value of the counter depending on the status of phases A and B pulses.

| Ladder | ST                       |

| (d)     | Number of the counter (device name) to be counted by the UDCNT2 instruction              | —               | Device name          | ANY16* <sup>2</sup>                                   |
| (s2)    | Set value                                                                                | -32768 to 32767 | 16-bit signed binary | ANY16                                                 |
| EN      | Execution condition                                                                      | —               | Bit                  | BOOL                                                  |
| ENO     | Execution result                                                                         | —               | Bit                  | BOOL                                                  |

\*1 Only labels assigned to device (X) can be used.

\*2 Only labels assigned to device (C) can be used.

### Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□\□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s1)    | ○* <sup>1</sup>                  | —    | —                                     | —           | — | —           | —  | —                      | —        | — | —  | —      |
| (d)     | —                                | —    | ○* <sup>2</sup>                       | —           | — | —           | —  | —                      | —        | — | —  | —      |
| (s2)    | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | —      |

\*1 Only X can be used. Note, however, that it can be used only within the range of the number of I/O points (the number of points that can access I/O modules).

\*2 Only C can be used.

## Processing details

- This instruction updates the current value of the counter specified by (d) depending on the status of the input (phase A pulse) specified by (s1) and the status of the input (phase B pulse) specified by (s1)+1.
- Counting up or down is determined as follows.
  - (s1)+1 is turned on while (s1) is on: Count-up (counting up the current value)
  - (s1)+1 is turned off while (s1) is on: Countdown (counting down the current value)
  - The instruction does not count while (s1) is off.
- Count processing is performed as follows.
  - When the current value equals the value specified by (s2) during count-up, the contact of the counter specified by (d) is turned on. The current value is kept counting even when the contact of the counter is turned on.
  - When the current value equals "the set value - 1" during countdown, the contact of the counter specified by (d) is turned off.
  - The counter specified by (d) is a ring counter. Counting up the counter when the current value is 32767 proceeds to -32768. Similarly, counting down the counter when the current value is -32768 proceeds to 32767. The following figure shows the processing for counting the current value.

- (1) When counting up  
(2) When counting down

- The following figure shows the operation of count processing using the UDCNT2 instruction.

### Ex.

Program which uses C0 (up/down counter) to count the states of X40 and X41 after X50 turns on

- (1) Current value of C0  
(2) Contact of C0
- When executed, the UDCNT2 instruction starts counting when the execution command turns on and stops counting when the command turns off. If the execution command is turned on again, the instruction resumes counting from the current value with which it stopped counting previously.
  - The RST instruction is used to clear the current value of the counter specified by (d) and turn off the contact.

## Point

- The UDCNT2 instruction stores the device data of the argument in the work area of the controller, and performs the actual count operation using system interrupts. (The device data stored in the work area of the controller is cleared by turning off the execution command or setting it to STOP then RUN.) For this reason, the pulses that can be counted must have longer on/off time than the interval of the controller. The interrupt interval of the controller is 1ms.
- The set value cannot be changed during counting by the UDCNT2 instruction (while the execution command is on). To change the set value, turn off the execution command in advance.
- The counter specified by the UDCNT2 instruction cannot be used by any other instruction. If another instruction uses it, normal counting is disabled.
- The UDCNT2 instruction can be used a maximum of five times in all running programs. The sixth or subsequent UDCNT1 instruction, if issued, causes no processing.

## Operation error

There is no operation error.

## 20.2 Special Timer Instructions

20

### Teaching timer

#### TTMR

This instruction measures the on time of the measurement command in seconds, multiplies it by a multiplier, and stores the operation result.

| Ladder | ST                 |
|--------|--------------------|
|        | ENO:=TTMR(EN,s,d); |
| FBD/LD |                    |

#### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| TTMR        |                     |

#### Setting data

#### Descriptions, ranges, and data types

| Operand | Description                                     | Range  | Data type            | Data type (label)                      |
|---------|-------------------------------------------------|--------|----------------------|----------------------------------------|
| (d)     | (d)+0: Device for storing the measurement value | —      | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 2) |
|         | (d)+1: For controller system                    |        |                      |                                        |
| (s)     | Multiplier of measurement value                 | 0 to 2 | 16-bit signed binary | ANY16                                  |
| EN      | Execution condition                             | —      | Bit                  | BOOL                                   |
| ENO     | Execution result                                | —      | Bit                  | BOOL                                   |

#### Applicable devices

| (s)     | —                                | ○    | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |

#### Control data

| Operand: (d) |                                          |               |        |
|--------------|------------------------------------------|---------------|--------|
| Device       | Description                              | Setting range | Set by |
| +0           | Device for storing the measurement value | —             | System |
| +1           | For controller system                    | —             | System |

## Processing details

- This instruction measures the on time of the execution command in seconds, multiplies it by the multiplier specified by (s), and stores the resultant value in the device specified by (d).
- When the execution command is turned on, the instruction clears the device specified by (d)+0, (d)+1.
- The table below lists the multipliers that can be specified by (s).

| (s) | Multiplier |
|-----|------------|
| 0   | 1          |
| 1   | 10         |
| 2   | 100        |

- When the value in the device specified by (s) is not in the range from 0 to 2, no processing is performed.

### Point

- When executed, the TTMR instruction implements time measurement. Do not use the JMP instruction to skip the TTMR instruction. Otherwise, accurate measurement is disabled.
- Do not change the multiplier specified by (s) during execution of the TTMR instruction. Otherwise, accurate values cannot be determined.
- The device specified by (d)+1 is used by the system of the controller. Do not change the value. If the value is changed, an accurate resultant value is not stored in the device specified by (d).

## Operation error

There is no operation error.

# Special function timer

20

## STMR

This instruction implements the following four types of timer output.

- Off delay timer output
- After-off one-shot timer output
- After-on one-shot timer output
- On delay + off delay timer output

| Ladder | ST                     |
|--------|------------------------|
|        | ENO:=STMR(EN,s1,s2,d); |

| FBD/LD |
|--------|
|        |

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| STMR        | Every scan          |

## Setting data

## Description, range, data type

| Operand | Description                                                                                                                                                  | Range      | Data type            | Data type (label)                       |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|----------------------|-----------------------------------------|
| (s1)    | Timer device or timer type label                                                                                                                             | —          | Device name          | ANY16                                   |
| (s2)    | Set value                                                                                                                                                    | 0 to 32767 | 16-bit signed binary | ANY16                                   |

\*1 Only T can be used.

## Processing details

- This instruction uses four points from the device specified by (d) to implement four types of timer output.

| Setting data | Description |                                   |                                                                                                                                                                                  |
|--------------|-------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (d)          | +0          | Off delay timer output:           | Turns on on the rising edge of the command of the STMR instruction, and turns off after a lapse of the time specified by (s2) after the falling edge of the command.             |
|              | +1          | After-off one-shot timer output   | Turns on on the falling edge of the command of the STMR instruction, and turns off after a lapse of the time specified by (s2).                                                  |
|              | +2          | After-on one-shot timer output    | Turns on on the falling edge of the command of the STMR instruction, and turns off after a lapse of the time specified by (s2) or when the command of the instruction turns off. |
|              | +3          | On delay + off delay timer output | Turns on on the falling edge of the timer coil, and turns off after a lapse of the time specified by (s2) after the falling edge of the command of the STMR instruction.         |

- The coil of the timer specified by (s1) turns on, on the rising and falling edges of the command of the STMR instruction, to start measurement of the current value.
- The coil of the timer keeps measurement during the time specified by (s2) and turns off when the time is up.
- The coil of the timer is kept on even if the STMR instruction is turned off before time-up. Timer measurement is continued. When the STMR instruction is turned on again, the coil resets the current value to 0 and restarts measurement.
- The contact of the timer turns on, on the rising edge of the command of the STMR instruction, and turns off on the falling edge of the command after the coil of the timer falls. Users cannot use the contact of the timer because it is reserved for the system.

- (1) Command for the STMR instruction  
 (2) Coil  
 (3) Contact  
 (4) Value specified by (s2)

- Measurement of the current value of the timer specified by the STMR instruction is executed regardless of whether the command of the STMR instruction is on or off. If the STMR instruction is skipped such as by the JMP instruction, normal measurement is not performed.
- The measurement unit of the timer specified by (d) is the same as that of the low-speed timer.
- A value from 0 to 32767 can be specified in (s2). If a value out of the range is specified, no processing is performed.
- Do not use the OUT instruction for the timer specified by (s1). If the same timer device or timer type label is used for the STMR and OUT instructions, normal operation is not performed.

## Precautions

If there is an STMR instruction within the range for changing the ladder block online or writing data to the running programmable controller, the STMR instruction is executed.

For details, refer to the following.

📖 User's manual for the controller used

## Operation error

There is no operation error.

# 21 CLOCK

## 21.1 Clock Instructions

### Reading clock data

#### DATERD(P)

Reads "year, month, day, hour, minute, second, and day of week" from the clock element of the controller.

| Ladder                                                                            | ST                                        |

## Processing details

- These instructions read "year, month, day, hour, minute, second, and day of week" from the clock element of the controller, and store the read data in binary in the device specified by (d) and later.

| (Data)          | (d)          | (d)+1   | (d)+2   | (d)+3   | (d)+4   | (d)+5   | (d)+6       |
|-----------------|--------------|---------|---------|---------|---------|---------|-------------|
| (Clock element) | Year         | Month   | Day     | Hour    | Minute  | Second  | Day of week |
| (Setting range) | 1980 to 2079 | 1 to 12 | 1 to 31 | 0 to 23 | 0 to 59 | 0 to 59 | 0 to 6      |

- "Year" stored in the device specified by (d) is a 4-digit year.
- "Day of week" stored in the device specified by (d)+6 is a number from 0 to 6 corresponding to Sunday to Saturday.

| Day of week | Sunday | Monday | Tuesday | Wednesday | Thursday | Friday | Saturday |
|-------------|--------|--------|---------|-----------|----------|--------|----------|
| Stored data | 0      | 1      | 2       | 3         | 4        | 5      | 6        |

- Data is automatically corrected in leap years.

## Operation error

There is no operation error.

# Writing clock data

## DATEWR(P)

Writes the clock data stored in the specified device and later to the clock element of the controller.

| Ladder | ST                                        |

## Processing details

- These instructions write the clock data stored in the specified device and later to the clock element of the controller.

| (Data)          | (d)          | (d)+1   | (d)+2   | (d)+3   | (d)+4   | (d)+5   | (d)+6       |
|-----------------|--------------|---------|---------|---------|---------|---------|-------------|
| (Clock element) | Year         | Month   | Day     | Hour    | Minute  | Second  | Day of week |
| (Setting range) | 1980 to 2079 | 1 to 12 | 1 to 31 | 0 to 23 | 0 to 59 | 0 to 59 | 0 to 6      |

- Set each data in binary.
- Set the year data in the range from 1980 to 2079 in the device specified by (s).
- Set the month data in the range from 1 to 12 in the device specified by (s)+1.
- Set the day data in the range from 1 to 31 in the device specified by (s)+2.
- Set the hour data in the range from 0 to 23 in the device specified by (s)+3. (Set in 24-hour format.)
- Set the minute data in the range from 0 to 59 in the device specified by (s)+4.
- Set the second data in the range from 0 to 59 in the device specified by (s)+5.
- Set the day of week in the range from 0 to 6 corresponding to Sunday to Saturday in the device specified by (s)+6.

| Day of week | Sunday | Monday | Tuesday | Wednesday | Thursday | Friday | Saturday |
|-------------|--------|--------|---------|-----------|----------|--------|----------|
| Stored data | 0      | 1      | 2       | 3         | 4        | 5      | 6        |

## Operation error

| Error code (SD0) | Description                                                                                            |
|------------------|--------------------------------------------------------------------------------------------------------|
| 3285H            | Out-of-range data is set in (s) to (s)+6.                                                              |
| 3295H            | A time value less than an hour from the start time of the daylight-saving time is set in (s) to (s)+6. |

### Point

When clock data is changed, "clock setting" (event code: 24000) is saved to the event history. Therefore, "clock setting" is saved to the event history when this instruction is executed.

# Adding clock data

## DATE+(P)

These instructions add time data.

| Ladder | ST                                                                |
|--------|-------------------------------------------------------------------|
|        | <pre>ENO:=DATEPLUS(EN,s1,s2,d); ENO:=DATEPLUSP(EN,s1,s2,d);</pre> |

## FBD/LD

(□ is replaced by either of the following: DATEPLUS, DATEPLUSP.)

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| DATE+       |                     |
| DATE+P      |                     |

## Setting data

## Descriptions, ranges, and data types

| Operand | Description                                                    | Range                          | Data type            | Data type (label)                      |
|---------|----------------------------------------------------------------|--------------------------------|----------------------|----------------------------------------|
| (s1)    | Start device where the augend clock data is stored             | Refer to "Processing details". | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| (s2)    | Start device where the addend time (clock) data is stored      | Refer to "Processing details". | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| (d)     | Start device for storing the addition result time (clock) data | —                              | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| EN      | Execution condition                                            | —                              | Bit                  | BOOL                                   |
| ENO     | Execution result                                               | —                              | Bit                  | BOOL                                   |

## Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|

| (s1)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions add the time data in the device specified by (s2) to the time data in the device specified by (s1), and store the addition result in the device number specified by (d) and later.

|        |        |           |   |        |        |           |   |       |        |           |
|--------|--------|-----------|---|--------|--------|-----------|---|-------|--------|-----------|
| (s1)   | hour   | (0 to 23) |   | (s2)   | hour   | (0 to 23) |   | (d)   | hour   | (0 to 23) |
| (s1)+1 | minute | (0 to 59) | + | (s2)+1 | minute | (0 to 59) | ⇒ | (d)+1 | minute | (0 to 59) |
| (s1)+2 | second | (0 to 59) |   | (s2)+2 | second | (0 to 59) |   | (d)+2 | second | (0 to 59) |

### Ex.

7:48:10 is added to 6:32:40.

|        |    |   |        |    |   |       |    |
|--------|----|---|--------|----|---|-------|----|
| (s1)   | 6  |   | (s2)   | 7  |   | (d)   | 14 |
| (s1)+1 | 32 | + | (s2)+1 | 48 | ⇒ | (d)+1 | 20 |
| (s1)+2 | 40 |   | (s2)+2 | 10 |   | (d)+2 | 50 |

- If the time obtained as the result of addition exceeds 24 hours, 24 hours are subtracted from the resultant time to produce the operation result. For example, when 20:20:20 is added to 14:20:30, the operation result is 10:40:50 rather than 34:40:50.

|        |    |   |        |    |   |       |    |
|--------|----|---|--------|----|---|-------|----|
| (s1)   | 14 |   | (s2)   | 20 |   | (d)   | 10 |
| (s1)+1 | 20 | + | (s2)+1 | 20 | ⇒ | (d)+1 | 40 |
| (s1)+2 | 30 |   | (s2)+2 | 20 |   | (d)+2 | 50 |

## Operation error

| Error code (SD0) | Description                                                       |
|------------------|-------------------------------------------------------------------|
| 3285H            | The data in the device specified by (s1) or (s2) is out of range. |

# Subtracting clock data

## DATE-(P)

These instructions subtract time data.

| Ladder | ST                                                                  |
|--------|---------------------------------------------------------------------|
|        | <pre>ENO:=DATEMINUS(EN,s1,s2,d); ENO:=DATEMINUSP(EN,s1,s2,d);</pre> |

## FBD/LD

(□ is replaced by either of the following: DATEMINUS, DATEMINUSP.)

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| DATE-       |                     |
| DATE-P      |                     |

## Setting data

## Descriptions, ranges, and data types

| Operand | Description                                                       | Range                          | Data type            | Data type (label)                      |
|---------|-------------------------------------------------------------------|--------------------------------|----------------------|----------------------------------------|
| (s1)    | Start device where minuend clock data is stored                   | Refer to "Processing details". | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| (s2)    | Start device where the subtrahend time (clock) data is stored     | Refer to "Processing details". | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| (d)     | Start device for storing the subtraction result time (clock) data | —                              | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 3) |
| EN      | Execution condition                                               | —                              | Bit                  | BOOL                                   |
| ENO     | Execution result                                                  | —                              | Bit                  | BOOL                                   |

## Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|

| (s1)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions subtract the time data in the device specified by (s2) from the time data in the device specified by (s1), and store the subtraction result in the device number specified by (d) and later.

|        |        |           |   |        |        |           |   |       |        |           |
|--------|--------|-----------|---|--------|--------|-----------|---|-------|--------|-----------|
| (s1)   | hour   | (0 to 23) |   | (s2)   | hour   | (0 to 23) |   | (d)   | hour   | (0 to 23) |
| (s1)+1 | minute | (0 to 59) | - | (s2)+1 | minute | (0 to 59) | ⇒ | (d)+1 | minute | (0 to 59) |
| (s1)+2 | second | (0 to 59) |   | (s2)+2 | second | (0 to 59) |   | (d)+2 | second | (0 to 59) |

### Ex.

3:50:10 is subtracted from 10:40:20.

|        |    |   |        |    |   |       |    |
|--------|----|---|--------|----|---|-------|----|
| (s1)   | 10 |   | (s2)   | 3  |   | (d)   | 6  |
| (s1)+1 | 40 | - | (s2)+1 | 50 | ⇒ | (d)+1 | 50 |
| (s1)+2 | 20 |   | (s2)+2 | 10 |   | (d)+2 | 10 |

- If the time obtained as the result of subtraction becomes a negative value, 24 hours are added to the resultant time to produce the operation result. For example, when 10:42:12 is subtracted from 4:50:32, the operation result is 18:8:20 rather than -6:8:20.

|        |    |   |        |    |   |       |    |
|--------|----|---|--------|----|---|-------|----|
| (s1)   | 4  |   | (s2)   | 10 |   | (d)   | 18 |
| (s1)+1 | 50 | - | (s2)+1 | 42 | ⇒ | (d)+1 | 8  |
| (s1)+2 | 32 |   | (s2)+2 | 12 |   | (d)+2 | 20 |

## Operation error

\*1 FX and FY cannot be used.

## Processing details

- These instructions convert the date and time data stored in the device number specified by (s) and later into second data, and store the operation result in the device specified by (d). The starting point (0 second) is January 1, 2000 at 00:00:00.

- The year data range is 2000 to 2067 for DATE2SEC(P) and 2000 to 2099 for DATE2SEC(P)\_U.

For example, the following shows when November 27, 2016 at 20:51:48 is specified.

- Changing clock data (including the time zone and time adjustment by daylight-saving time) does not affect the operation of these instructions. For example, the operation result during the season when the daylight-saving time is applied is same as the result during the season when the daylight-saving time is not applied.

## Operation error

| Error code (SD0) | Description                                                             |

\*1 FX and FY cannot be used.

## Processing details

- These instructions convert the second data stored in the device number specified by (s) and later into date and time data, and store the operation result in the device specified by (d) and later. The starting point (0 second) is January 1, 2000 at 00:00:00.

For example, the following shows 1880337074 seconds are specified.

- Day of week stored in the device specified by (d)+6 is a number from "0 to 6" corresponding to "Sunday to Saturday".

| Day of week | Sunday | Monday | Tuesday | Wednesday | Thursday | Friday | Saturday |
|-------------|--------|--------|---------|-----------|----------|--------|----------|
| Stored data | 0      | 1      | 2       | 3         | 4        | 5      | 6        |

- Changing clock data (including the time zone and time adjustment by daylight-saving time) does not affect the operation of these instructions. For example, the operation result during the season when the daylight-saving time is applied is same as the result during the season when the daylight-saving time is not applied.

## Operation error

| Error code (SD0) | Description                                           |
|------------------|-------------------------------------------------------|
| 3285H            | The data in the device specified (s) is out of range. |

# Comparing date data

## LDDT□, ANDDT□, ORDT□

These instructions compare the specified date data, or compare the date data with the current date.

| Ladder                                                                     | ST                                                                                                                                                             |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>(□ indicates DT=, DT&lt;&gt;, DT&gt;, DT&lt;=, DT&lt;, or DT&gt;=.)</p> | <pre> ENO:=LDDT_□(EN,s1,s2,s3); ENO:=ANDDT_□(EN,s1,s2,s3); ENO:=ORDT_□(EN,s1,s2,s3); (□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)*1 </pre> |

## FBD/LD

(□ is replaced by a combination of LDDT\_, ANDDT\_, or ORDT\_ and EQ, NE, GT, LE, LT, or GE.)\*1

\*1 EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

## Execution condition

| Instruction          | Execution condition |
|----------------------|---------------------|
| LDDT□, ANDDT□, ORDT□ | Every scan          |

## Setting data

## Description, range, data type

| Operand | Description                                                             | Range                          | Data type            | Data type (label) |
|---------|-------------------------------------------------------------------------|--------------------------------|----------------------|-------------------|
| (s1)    | Start device where the data to be compared is stored                    | —                              | 16-bit signed binary | ANY_DT*1          |
| (s2)    | Start device where the data to be compared is stored                    | —                              | 16-bit signed binary | ANY_DT*1          |
| (s3)    | Comparison target setting value or the number of comparison target data | 0001H to 0007H, 8001H to 8007H | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                                     | —                              | Bit                  | BOOL              |
| ENO     | Execution result                                                        | —                              | Bit                  | BOOL              |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

## Processing details

- These instructions compare the date data in the devices specified by (s1) and (s2), or compare the date data in the device specified by (s1) with the current date. Set the comparison target by (s3).

- Comparing two specified date data

These instructions compare the date data in the device specified by (s1) with the date data in the device specified by (s2) in accordance with the conditions set by (s3). (Devices are used as a normally open contact.)

(1)Relational operator

(2)Comparison result

- Comparing the specified date data with the current date

These instructions compare the date data in the device specified by (s1) with the current date data in accordance with the conditions set by (s3). (Devices are used as a normally open contact.) The date data in the device specified by (s2) is regarded as dummy data and ignored.

(1)Relational operator

(2)Current date data

(3)Comparison result

- Set each data in binary.
- Set the year data in the range from 1980 to 2079 in the devices specified by (s1) and (s2).
- Set the month data in the range from 1 to 12 in the devices specified by (s1)+1 and (s2)+1.
- Set the date data in the range from 1 to 31 in the devices specified by (s1)+2 and (s2)+2.
- Set the following in (s3) as comparison target setting values. The following shows the bit configuration of (s3).

- (1) Set "day" as comparison target.
- (2) Set "month" as comparison target.
- (3) Set "year" as comparison target.
- (4) Set 0. If a value other than 0 is set, the operation result will be non-continuity.
- (5) When bit 15 turns on (1), the data in the device specified by (s1) is compared with the current date in accordance with the conditions set in bits 0 to 2.

- When 0 is set to bits 0 to 2, the date data are not compared. When 1 is set, the entire date data (year, month, and day) are compared.
- When 0 is set to bit 15, the data in the device specified by (s1) and the date data in the device specified by (s2) are compared. When 1 is set, the data in the device specified by (s1) is compared with the current date. The date data in the device specified by (s2) is ignored.

- The following table lists processing details of each bit.

| (s3) value when comparing two specified date data | (s3) value when comparing the specified date data with the current date | Comparison target | Description                                                                                                                                     |
|---------------------------------------------------|-------------------------------------------------------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001H                                             | 8001H                                                                   | Day               | Only data in the device specified by (s1)+2 is compared.                                                                                        |
| 0002H                                             | 8002H                                                                   | Month             | Only data in the device specified by (s1)+1 is compared.                                                                                        |
| 0003H                                             | 8003H                                                                   | Month, day        | Data in the device areas specified by (s1)+1 and (s1)+2 are compared.                                                                           |
| 0004H                                             | 8004H                                                                   | Year              | Only data in the device specified by (s1) is compared.                                                                                          |
| 0005H                                             | 8005H                                                                   | Year, day         | Data in the device areas specified by (s1) and (s1)+2 are compared.                                                                             |
| 0006H                                             | 8006H                                                                   | Year, month       | Data in the device areas specified by (s1) and (s1)+1 are compared.                                                                             |
| 0007H                                             | 8007H                                                                   | Year, month, day  | The entire date data in the device areas specified by (s1), (s1)+1, and (s1)+2 are compared.                                                    |
| Other than 0001H to 0007H, 8001H to 8007H         |                                                                         | None              | The entire date data in the device areas specified by (s1), (s1)+1, and (s1)+2 are not compared. (The operation result will be non-continuity.) |

- If the comparison target data in the device are not recognized as date data, SM709 (DT/TM instruction improper data detection flag) turns on after the instruction is executed and the operation result will be non-continuity. Even if the data are not recognized as date data, SM709 does not turn on if the data are within the setting range. If the device areas specified by (s1) to (s1)+2 or (s2) to (s2)+2 exceed the assignment range of the relevant device/label, SM709 turns on after the instruction is executed and the operation result will be non-continuity as well. Once SM709 turns on, the on state is held until the controller is powered off or reset. Turn off SM709 as needed.
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result                             |
|-------------------------------------|-----------|------------------------------------|
| DT=, EQ                             | (s1)=(s2) | Continuity state (ENO is on.)      |
| DT<>, NE                            | (s1)≠(s2) |                                    |
| DT>, GT                             | (s1)>(s2) |                                    |
| DT<=, LE                            | (s1)≤(s2) |                                    |
| DT<, LT                             | (s1)<(s2) |                                    |
| DT>=, GE                            | (s1)≥(s2) |                                    |
| DT=, EQ                             | (s1)≠(s2) | Non-continuity state (ENO is off.) |
| DT<>, NE                            | (s1)=(s2) |                                    |
| DT>, GT                             | (s1)≤(s2) |                                    |
| DT<=, LE                            | (s1)>(s2) |                                    |
| DT<, LT                             | (s1)≥(s2) |                                    |
| DT>=, GE                            | (s1)<(s2) |                                    |

**Ex.**

The date data A, B, and C are compared.

- The following table lists the comparison operation results between A, B, and C. Even when the data are compared under the same conditions, the results differ depending on the comparison target data.

| Comparison target data | Condition <sup>*1</sup> |                |                |
|------------------------|-------------------------|----------------|----------------|
|                        | A<B                     | B<C            | A<C            |
| Day                    | Continuity              | Non-continuity | Non-continuity |
| Month                  | Non-continuity          | Continuity     | Non-continuity |
| Month, day             | Non-continuity          | Continuity     | Non-continuity |
| Year                   | Continuity              | Continuity     | Continuity     |
| Year, day              | Continuity              | Continuity     | Continuity     |
| Year, month            | Continuity              | Continuity     | Continuity     |
| Year, month, day       | Continuity              | Continuity     | Continuity     |
| None                   | Non-continuity          | Non-continuity | Non-continuity |

<sup>\*1</sup> In FBD/LD, ENO ON indicates continuity and ENO OFF indicates non-continuity.

- Even though the specified date does not exist, the comparison operation is performed in accordance with the conditions in the following table as long as the date data are within the valid range.
  - Date A: 2006/02/30 (Even though the date does not exist, this date can be set.)
  - Date B: 2007/03/29
  - Date C: 2008/02/31 (Even though the date does not exist, this date can be set.)

| Comparison target data | Condition <sup>*2</sup> |                |                |
|------------------------|-------------------------|----------------|----------------|
|                        | A<B                     | B<C            | A<C            |
| Day                    | Non-continuity          | Continuity     | Continuity     |
| Month                  | Continuity              | Non-continuity | Non-continuity |
| Month, day             | Continuity              | Non-continuity | Continuity     |
| Year                   | Continuity              | Continuity     | Continuity     |
| Year, day              | Continuity              | Continuity     | Continuity     |
| Year, month            | Continuity              | Continuity     | Continuity     |
| Year, month, day       | Continuity              | Continuity     | Continuity     |
| None                   | Non-continuity          | Non-continuity | Non-continuity |

<sup>\*2</sup> In FBD/LD, ENO ON indicates continuity and ENO OFF indicates non-continuity.

- If the LDDT\_□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the ORDT\_□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.

## Operation error

There is no operation error.

# Comparing time data

## LDTM□, ANDTM□, ORTM□

These instructions compare the specified time data, or compare the specified time data with the current time.

| Ladder                                                                          | ST                                                                                                                                                                             |
|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>(□ is replaced by TM=, TM&lt;&gt;, TM&gt;, TM&lt;=, TM&lt;, or TM&gt;=.)</p> | <pre>ENO:=LDTM_□(EN,s1,s2,s3); ENO:=ANDTM_□(EN,s1,s2,s3); ENO:=ORTM_□(EN,s1,s2,s3);</pre> <p>(□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)*<sup>1</sup></p> |

## FBD/LD

(□ is replaced by a combination of LDTM\_, ANDTM\_, or ORTM\_ and EQ, NE, GT, LE, LT, or GE.)\*<sup>1</sup>

\*<sup>1</sup> EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

## Execution condition

| Instruction          | Execution condition |
|----------------------|---------------------|
| LDTM□, ANDTM□, ORTM□ | Every scan          |

## Setting data

## Description, range, data type

| Operand | Description                                                             | Range                             | Data type            | Data type (label)    |

## Processing details

- These instructions compare the time data in the device specified by (s1) and (s2), or compare the time data in the device specified by (s1) with the current time. Set the comparison target by (s3).

- Comparing two specified time data

These instructions compare the time data in the device specified by (s1) with the time data (hour, minute, second) in the device specified by (s2) in accordance with the conditions set by (s3). (Devices are used as a normally open contact.)

(1)Relational operator

(2)Comparison result

- Comparing the specified time data with the current time data

These instructions compare the time data in the device specified by (s1) with the current time data in accordance with the conditions set by (s3). (Devices are used as a normally open contact.) The time data in the device specified by (s2) is regarded as dummy data and ignored.

(1)Relational operator

(2)Current time data

(3)Comparison result

- Set each data in binary.
- Set the hour data in the range from 0 to 23 in 24-hour format in the devices specified by (s1) and (s2).
- Set the minute data in the range from 0 to 59 in the devices specified by (s1)+1 and (s2)+1.
- Set the second data in the range from 0 to 59 in the devices specified by (s1)+2 and (s2)+2.
- Set the following in (s3) as comparison target setting values. The following shows the bit configuration of (s3).

- (1) Set "second" as comparison target.
- (2) Set "minute" as comparison target.
- (3) Set "hour" as comparison target.
- (4) Set 0. If a value other than 0 is set, the operation result will be non-continuity.
- (5) When bit 15 turns on (1), the data in the device specified by (s1) is compared with the current time in accordance with the conditions set in bits 0 to 2.

- When 0 is set to bits 0 to 2, the time data are not compared. When 1 is set, the comparison target time data (hour, minute, second) are compared.
- When 0 is set to bit 15, the data in the device specified by (s1) and the time data in the device specified by (s2) are compared. When 1 is set, the time data in the device specified by (s1) is compared with the current time. The time data in the device specified by (s2) is ignored.
- The following table lists processing details of each bit.

| (s3) value when comparing two specified time data | (s3) value when comparing with current time data | Comparison target time | Description                                                                                                                                     |
|---------------------------------------------------|--------------------------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001H                                             | 8001H                                            | Second                 | Only data in the device specified by (s1)+2 is compared.                                                                                        |
| 0002H                                             | 8002H                                            | Minute                 | Only data in the device specified by (s1)+1 is compared.                                                                                        |
| 0003H                                             | 8003H                                            | Minute, second         | Data in the device areas specified by (s1)+1 and (s1)+2 are compared.                                                                           |
| 0004H                                             | 8004H                                            | Hour                   | Only data in the device specified by (s1) is compared.                                                                                          |
| 0005H                                             | 8005H                                            | Hour, second           | Data in the device areas specified by (s1) and (s1)+2 are compared.                                                                             |
| 0006H                                             | 8006H                                            | Hour, minute           | Data in the device areas specified by (s1) and (s1)+1 are compared.                                                                             |
| 0007H                                             | 8007H                                            | Hour, minute, second   | The entire date data in the device areas specified by (s1), (s1)+1, and (s1)+2 are compared.                                                    |
| Other than 0001H to 0007H, 8001H to 8007H         |                                                  | None                   | The entire date data in the device areas specified by (s1), (s1)+1, and (s1)+2 are not compared. (The operation result will be non-continuity.) |

- If the comparison target data in the device are not recognized as time data, SM709 (DT/TM instruction improper data detection flag) turns on after the instruction is executed and the operation result will be non-continuity (ENO OFF). If the device areas specified by (s1) to (s1)+2 or (s2) to (s2)+2 exceed the assignment range of the relevant device/label, SM709 turns on after the instruction is executed and the operation result will be non-continuity (ENO OFF) as well. Once SM709 turns on, the on state is held until the controller is powered off or reset. Turn off SM709 as needed.
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result                             |
|-------------------------------------|-----------|------------------------------------|
| TM=, EQ                             | (s1)=(s2) | Continuity state (ENO is on.)      |
| TM<>, NE                            | (s1)≠(s2) |                                    |
| TM>, GT                             | (s1)>(s2) |                                    |
| TM<=, LE                            | (s1)≤(s2) |                                    |
| TM<, LT                             | (s1)<(s2) |                                    |
| TM>=, GE                            | (s1)≥(s2) |                                    |
| TM=, EQ                             | (s1)≠(s2) | Non-continuity state (ENO is off.) |
| TM<>, NE                            | (s1)=(s2) |                                    |
| TM>, GT                             | (s1)≤(s2) |                                    |
| TM<=, LE                            | (s1)>(s2) |                                    |
| TM<, LT                             | (s1)≥(s2) |                                    |
| TM>=, GE                            | (s1)<(s2) |                                    |

#### Ex.

The time data A, B, and C are compared.

- The following table lists the comparison operation results between A, B, and C. Even when the data are compared under the same conditions, the results differ depending on the comparison target data.

| Comparison target data | Condition <sup>*1</sup> |                |                |
|------------------------|-------------------------|----------------|----------------|
|                        | A<B                     | B<C            | A<C            |
| Second                 | Continuity              | Non-continuity | Non-continuity |
| Minute                 | Non-continuity          | Continuity     | Non-continuity |
| Minute, second         | Non-continuity          | Continuity     | Non-continuity |
| Hour                   | Continuity              | Continuity     | Continuity     |
| Hour, second           | Continuity              | Continuity     | Continuity     |
| Hour, minute           | Continuity              | Continuity     | Continuity     |
| Hour, minute, second   | Continuity              | Continuity     | Continuity     |
| None                   | Non-continuity          | Non-continuity | Non-continuity |

<sup>\*1</sup> In FBD/LD, ENO ON indicates continuity and ENO OFF indicates non-continuity.

- If the LDTM\_□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the ORTM\_□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.

## Operation error

There is no operation error.

# Outputting a comparison result of time data

## TCMP(P)

These instructions compare the time data to be compared that is specified by (s1), (s2), and (s3) with the time data specified by (s4), and according to the result (small, match, or large), (d), (d)+1, or (d)+2 is turned on.

| Ladder | ST                                                            |
|--------|---------------------------------------------------------------|
|        | ENO:=TCMP(EN,s1,s2,s3,s4,d);<br>ENO:=TCMPP(EN,s1,s2,s3,s4,d); |

# Reading expansion clock data

21

## S(P).DATERD

These instructions read clock data including millisecond from the clock elements in the controller.

| Ladder                                                                            | ST                                            |
|-----------------------------------------------------------------------------------|-----------------------------------------------|
|  | ENO:=S_DATERD(EN,d);<br>ENO:=SP_DATERD(EN,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Execution condition

| Instruction | Execution condition                                                               |
|-------------|-----------------------------------------------------------------------------------|
| S.DATERD    |  |
| SP.DATERD   |  |

### Setting data

### Description, range, data type

| Operand | Description                                                | Range | Data type            | Data type (label)                      |
|---------|------------------------------------------------------------|-------|----------------------|----------------------------------------|
| (d)     | Start device for storing the clock data that has been read | —     | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 8) |
| EN      | Execution condition                                        | —     | Bit                  | BOOL                                   |
| ENO     | Execution result                                           | —     | Bit                  | BOOL                                   |

### Applicable devices

| Operand | Bit                              |     | Word                                  |            | Z | Double word |    | Indirect specification | Constant |   |    |   | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|---|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□ |   | LT, LST, LC | LZ |                        | K, H     | E | \$ |   |        |
| (d)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | — | —      |

## Processing details

- These instructions read "year, month, day, hour, minute, second, day of week, and 1/1000 second" from the clock element of the controller, and store the read data in binary in the device specified by (d) and later.

| (Data)          | (d)          | (d)+1   | (d)+2   | (d)+3   | (d)+4   | (d)+5   | (d)+6       | (d)+7       |
|-----------------|--------------|---------|---------|---------|---------|---------|-------------|-------------|
| (Clock element) | Year         | Month   | Day     | Hour    | Minute  | Second  | Day of week | Millisecond |
| (Setting range) | 1980 to 2079 | 1 to 12 | 1 to 31 | 0 to 23 | 0 to 59 | 0 to 59 | 0 to 6      | 0 to 999    |

- "Year" stored in the device specified by (d) is a 4-digit year.
- "Day of week" stored in the device specified by (d)+6 is a number from 0 to 6 corresponding to Sunday to Saturday.

| Day of week | Day | Month | Tuesday | Wednesday | Thursday | Friday | Saturday |
|-------------|-----|-------|---------|-----------|----------|--------|----------|
| Stored data | 0   | 1     | 2       | 3         | 4        | 5      | 6        |

- Data is automatically corrected in leap years.

## Precautions

- S(P).DATERD instruction reads clock data and store it in the device even when incorrect clock data is set in the controller. (Example: February 30) When setting clock data with the DATEWR(P) instruction or engineering tool, be careful not to set incorrect clock data.
- When millisecond clock data is read, the maximum error is 2ms. (This error means the difference between the data stored in clock elements in the controller and the data read by the S(P).DATERD instruction.)

## Operation error

There is no operation error.

# Adding expansion clock data

## S(P).DATE+

These instructions add time data.

| Ladder | ST                                                                    |
|--------|-----------------------------------------------------------------------|
|        | <pre>ENO:=S_DATEPLUS(EN,s1,s2,d); ENO:=SP_DATEPLUS(EN,s1,s2,d);</pre> |

## FBD/LD

(□ is replaced by either of the following: S\_DATEPLUS, SP\_DATEPLUS.)

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| S.DATE+     |                     |
| SP.DATE+    |                     |

## Setting data

## Descriptions, ranges, and data types

| Operand | Description                                                    | Range                          | Data type            | Data type (label)                      |
|---------|----------------------------------------------------------------|--------------------------------|----------------------|----------------------------------------|
| (s1)    | Start device where the augend clock data is stored             | Refer to "Processing details". | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 5) |
| (s2)    | Start device where the addend time (clock) data is stored      | Refer to "Processing details". | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 5) |
| (d)     | Start device for storing the addition result time (clock) data | —                              | 16-bit signed binary | ANY16_ARRAY<br>(Number of elements: 5) |
| EN      | Execution condition                                            | —                              | Bit                  | BOOL                                   |
| ENO     | Execution result                                               | —                              | Bit                  | BOOL                                   |

## Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□\□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s1)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions add the time data in the device specified by (s2) to the time data in the device specified by (s1), and store the addition result in the device number specified by (d) and later.

|        |              |            |        |              |            |       |              |            |
|--------|--------------|------------|--------|--------------|------------|-------|--------------|------------|
| (s1)   | hour         | (0 to 23)  | (s2)   | hour         | (0 to 23)  | (d)   | hour         | (0 to 23)  |
| (s1)+1 | minute       | (0 to 59)  | (s2)+1 | minute       | (0 to 59)  | (d)+1 | minute       | (0 to 59)  |
| (s1)+2 | second       | (0 to 59)  | (s2)+2 | second       | (0 to 59)  | (d)+2 | second       | (0 to 59)  |
| (s1)+3 | —            |            | (s2)+3 | —            |            | (d)+3 | —            |            |
| (s1)+4 | 1/1000second | (0 to 999) | (s2)+4 | 1/1000second | (0 to 999) | (d)+4 | 1/1000second | (0 to 999) |

### Ex.

7:48:10:500 is added to 6:32:40:875.

|        |     |        |     |       |     |
|--------|-----|--------|-----|-------|-----|
| (s1)   | 6   | (s2)   | 7   | (d)   | 14  |
| (s1)+1 | 32  | (s2)+1 | 48  | (d)+1 | 20  |
| (s1)+2 | 40  | (s2)+2 | 10  | (d)+2 | 51  |
| (s1)+3 | —   | (s2)+3 | —   | (d)+3 | —   |
| (s1)+4 | 875 | (s2)+4 | 500 | (d)+4 | 375 |

- If the time obtained as the result of addition exceeds 24 hours, 24 hours are subtracted from the resultant time to produce the operation result. For example, when 20:20:20:500 is added to 14:20:30:875, the operation result is 10:40:51:375 rather than 34:40:51:375.

|        |     |        |     |       |     |
|--------|-----|--------|-----|-------|-----|
| (s1)   | 14  | (s2)   | 20  | (d)   | 10  |
| (s1)+1 | 20  | (s2)+1 | 20  | (d)+1 | 40  |
| (s1)+2 | 30  | (s2)+2 | 20  | (d)+2 | 51  |
| (s1)+3 | —   | (s2)+3 | —   | (d)+3 | —   |
| (s1)+4 | 875 | (s2)+4 | 500 | (d)+4 | 375 |

## Point

- Devices (s1)+3, (s2)+3, and (d)+3 are not used for operation.
- The clock data that has been read by the S(P).DATERD instruction can be added without conversion.

|       |             |
|-------|-------------|
| (d)   | Hour        |
| (d)+1 | Minute      |
| (d)+2 | Second      |
| (d)+3 | Day of week |
| (d)+4 | Millisecond |

When clock data is read by the S(P).DATERD instruction, "day of week" is inserted between "second" and "millisecond".

If the S(P).DATE+ instruction is used to read clock data, the data can be directly used for addition since it does not perform calculation for the day of week.

## Operation error

| Error code (SD0) | Description                                                       |
|------------------|-------------------------------------------------------------------|
| 3285H            | The data in the device specified by (s1) or (s2) is out of range. |

# Subtracting expansion clock data

21

## S(P).DATE-

These instructions subtract time data.

| Ladder | ST                                                                      |

| (s2)    | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions subtract the time data in the device specified by (s2) from the time data in the device specified by (s1), and store the subtraction result in the device number specified by (d) and later.

|        |              |            |        |              |            |       |              |            |
|--------|--------------|------------|--------|--------------|------------|-------|--------------|------------|
| (s1)   | hour         | (0 to 23)  | (s2)   | hour         | (0 to 23)  | (d)   | hour         | (0 to 23)  |
| (s1)+1 | minute       | (0 to 59)  | (s2)+1 | minute       | (0 to 59)  | (d)+1 | minute       | (0 to 59)  |
| (s1)+2 | second       | (0 to 59)  | (s2)+2 | second       | (0 to 59)  | (d)+2 | second       | (0 to 59)  |
| (s1)+3 | —            |            | (s2)+3 | —            |            | (d)+3 | —            |            |
| (s1)+4 | 1/1000second | (0 to 999) | (s2)+4 | 1/1000second | (0 to 999) | (d)+4 | 1/1000second | (0 to 999) |

### Ex.

3:50:10:500 is subtracted from 10:40:20:875.

|        |     |        |     |       |     |
|--------|-----|--------|-----|-------|-----|
| (s1)   | 10  | (s2)   | 3   | (d)   | 6   |
| (s1)+1 | 40  | (s2)+1 | 50  | (d)+1 | 50  |
| (s1)+2 | 20  | (s2)+2 | 10  | (d)+2 | 10  |
| (s1)+3 | —   | (s2)+3 | —   | (d)+3 | —   |
| (s1)+4 | 875 | (s2)+4 | 500 | (d)+4 | 375 |

- If the time obtained as the result of subtraction becomes a negative value, 24 hours are added to the resultant time to produce the operation result. For example, when 10:42:12:500 is subtracted from 4:50:32:875, the operation result is 18:8:20:375 rather than -6:8:20:375.

|        |     |        |     |       |     |
|--------|-----|--------|-----|-------|-----|
| (s1)   | 4   | (s2)   | 10  | (d)   | 18  |
| (s1)+1 | 50  | (s2)+1 | 42  | (d)+1 | 8   |
| (s1)+2 | 32  | (s2)+2 | 12  | (d)+2 | 20  |
| (s1)+3 | —   | (s2)+3 | —   | (d)+3 | —   |
| (s1)+4 | 875 | (s2)+4 | 500 | (d)+4 | 375 |

## Point

- Devices (s1)+3, (s2)+3, and (d)+3 are not used for operation.
- The clock data that has been read by the S(P).DATERD instruction can be subtracted without conversion.

|       |             |
|-------|-------------|
| (d)   | Hour        |
| (d)+1 | Minute      |
| (d)+2 | Second      |
| (d)+3 | Day of week |
| (d)+4 | Millisecond |

When clock data is read by the S(P).DATERD instruction, "day of week" is inserted between "second" and "millisecond".

If the S(P).DATE- instruction is used to read clock data, the data can be directly used for subtraction since it does not perform calculation for the day of week.

## Operation error

| Error code (SD0) | Description                                                       |
|------------------|-------------------------------------------------------------------|
| 3285H            | The data in the device specified by (s1) or (s2) is out of range. |

## 21.2 Timing Check Instructions

### Generating timing pulses

#### DUTY

This instruction turns on the user timing clock for the specified number of scans and off for the specified number of scans.

| Ladder | ST                     |
|--------|------------------------|
|        | ENO:=DUTY(EN,n1,n2,d); |

| FBD/LD |
|--------|
|        |

#### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| DUTY        |                     |

#### Setting data

#### Descriptions, ranges, and data types

| Operand | Description                                                     | Range          | Data type              | Data type (label)      |
|---------|-----------------------------------------------------------------|----------------|------------------------|------------------------|
| (n1)    | Number of scans during which the clock is turned on             | 0 to 65535     | 16-bit unsigned binary | ANY16                  |
| (n2)    | Number of scans during which the clock is turned off            | 0 to 65535     | 16-bit unsigned binary | ANY16                  |

| (d)     | ○ <sup>*1</sup>                  | —   | —                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |

<sup>\*1</sup> Only SM420 to SM424 can be used.

## Processing details

- This instruction turns on SM420 to SM424 in the device specified by (d) for the number of scans specified by (n1) and turns it off for the number of scans specified by (n2).

(n1): (n1) scans

(n2): (n2) scans

- The scan execution type program uses SM420 to SM424.
- When 0 is specified in (n1) and (n2) is equal to or greater than 0, SM420 to SM424 stay off. When (n1) is greater than 0 and (n2) is 0, SM420 to SM424 stay on.
- When the DUTY instruction is executed, the data specified by (n1), (n2), and (d) is stored in the system, and the timing pulses are turned on or off by the END processing.

## Operation error

| Error code (SD0) | Description                                               |
|------------------|-----------------------------------------------------------|
| 2820H            | The device other than SM420 to SM424 is specified by (d). |

## Measuring time of the specified data

### TIMCHK

This instruction measures the on time of the device and, if the on time has continued as specified or longer, turns on the specified device.

| Ladder | ST                       |
|--------|--------------------------|
|        | ENO:=TIMCHK(EN,s1,s2,d); |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| TIMCHK      |                     |

### Setting data

### Description, range, data type

| Operand | Description                                                                                         | Range      | Data type            | Data type (label) |
|---------|-----------------------------------------------------------------------------------------------------|------------|----------------------|-------------------|
| (s1)    | Device for storing the current value measured (unit: 100ms)                                         | —          | 16-bit signed binary | ANY16             |
| (s2)    | Set value for measurement or the device where the set value for measurement is stored (unit: 100ms) | 0 to 32767 | 16-bit signed binary | ANY16             |
| (d)     | Device to be turned on at time-up                                                                   | —          | Bit                  | ANY_BOOL          |
| EN      | Execution condition                                                                                 | —          | Bit                  | BOOL              |
| ENO     | Execution result                                                                                    | —          | Bit                  | BOOL              |

### Applicable devices

| (d)     | ○                                | —    | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- This instruction measures the on time of the device and, if the on time has continued as specified in the device specified by (s2) or longer, turns on the device specified by (d).
- The current value in the device specified by (s1) is cleared to 0 and the device specified by (d) is turned off on the rising edge of the execution command. The current value in the device specified by (s1) and the on state of the device specified by (d) are retained even after the execution command turns off.
- The current value measured is stored in units of 100ms. Set the measurement time in increments of 100ms.
- If 0 is specified in (s2), the current value in the device specified by (s1) is cleared to 0 and the device specified by (d) is turned off on the rising edge of the execution command.
- If a number other than 0 to 32767 is specified in (s2), (d) is turned on at the next scan after the execution command turns on.

## Operation error

There is no operation error.

# 22 MODULE ACCESS

22

## 22.1 Module Access Instructions

### Performing I/O refresh

#### RFS(P)

These instructions refresh the n points of data from the specified device, and import external inputs or output data to the output module.

| Ladder                                                                            | ST                                      |
|-----------------------------------------------------------------------------------|-----------------------------------------|
|  | ENO:=RFS(EN,s,n);<br>ENO:=RFSP(EN,s,n); |

#### FBD/LD

#### ■Execution condition

| Instruction | Execution condition                                                                 |
|-------------|-------------------------------------------------------------------------------------|
| RFS         |  |
| RFSP        |  |

#### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                  | Range     | Data type              | Data type (label) |
|---------|------------------------------|-----------|------------------------|-------------------|
| (s)     | Start device to be refreshed | —         | Bit                    | ANY_BOOL*1        |
| (n)     | Number of refreshed points   | 1 to 4096 | 16-bit unsigned binary | ANY16             |
| EN      | Execution condition          | —         | Bit                    | BOOL              |
| ENO     | Execution result             | —         | Bit                    | BOOL              |

\*1 Only labels assigned to devices (X, Y) can be used.

#### ■Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○*1                              | —    | —                                     | —           | — | —           | —  | —                      | —        | — | —  | —      |
| (n)     | —                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | —      |

\*1 Only X and Y can be used.

## Processing details

- This instruction refreshes only the relevant device during one scan, and imports external inputs or outputs data to the output module.
- The instruction imports external inputs and outputs data to the outside altogether only after execution of the END instruction of the program, and therefore cannot output pulse signals to the outside during one scan. When executed, the I/O refresh instruction forcibly refreshes the relevant input (X) and output (Y) during program execution and therefore can output pulse signals to the outside during one scan.
- To refresh the input (X) or output (Y) in units of points, use the direct access input (DX) or direct access output (DY).

### Ex.

When a program using the RFS instruction is changed to a program using direct access input/output

- (1) Refresh X40.  
 (2) Refresh Y60.  
 (3) Direct access input  
 (4) Direct access output

## Operation error

| Error code (SD0) | Description                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------|

| Built-in motion function part  | 42H                    |

### ■FROM(P)

- This instruction reads (n) words of data from the buffer memory address specified by (s) in the module specified by (U/H), and stores in the device specified by (d) and later.

- If the read data (n) is 0, no processing is performed.
- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

### ■DFROM(P)

- This instruction reads (n)×2 words of data from the buffer memory address specified by (s) in the module specified by (U/H), and stores in the device specified by (d) and later.

- If the read data (n) is 0, no processing is performed.
- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

| Error code (SD0) | Description                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | The module with the I/O number specified by (U) does not have buffer memory.                                                       |
| 2823H            | The module with the I/O number specified by (H) does not have buffer memory.                                                       |
|                  | The address specified by (s) is outside the range of buffer memory.                                                                |
|                  | The (n) points of data starting from the address specified by (s) are outside the range of buffer memory. (FROM(P) instruction)    |
|                  | The 2×(n) points of data starting from the address specified by (s) are outside the range of buffer memory. (DFROM(P) instruction) |
| 3602H            | This instruction is executed for the intelligent module in an interrupt program with the priority 1 to 16.                         |

## Point

- Module data can also be read using the module access device. (📖User's manual for the controller used)
- If refresh settings are not made for the refresh area of the read/write enabled area in the CPU buffer memory, the area can be used as a read/write specifiable area. Even when refresh settings are made, the area can be used as a read/write specifiable area in the reference send range and later. If the intelligent module number U40\G0 or U42\G0 of the CC-Link IE TSN function part or motion function part is specified in the operand (U/H), the following range can be accessed.

- A CPU buffer memory access device can be used to read data from the CPU buffer memory. (📖User's manual for the controller used)
- The FROM(P) and DFROM(P) instructions can read data from the buffer memory address with a capacity of 64K words or less. To read data from the buffer memory address with a capacity exceeding 64K words, use the FROMD(P) or DFROMD(P) instruction. (📖Page 1017 FROMD(P), DFROMD(P))

# Writing 1-word/2-word data to a module (16-bit specification)

## TO(P), DTO(P)

- TO(P): This instruction writes the n points of data from the specified device to the buffer memory in the module.
- DTO(P): This instruction writes the n×2 points of data from the specified device to the buffer memory in the module.

\*1 Only the DTO(P) instruction can be used.

## Processing details

Specify the intelligent module numbers of the controller as shown in the table below.

| Controller                     | Intelligent module No. |
|--------------------------------|------------------------|
| CPU function part              | 3E0H                   |
| Built-in network function part | 40H                    |
| Built-in motion function part  | 42H                    |

### ■TO(P)

- This instruction writes the  $n$  points of data from the device specified by (s2) to the buffer memory address specified by (s1) and later in the buffer memory in the module or host controller specified by (U/H).
- Writing word data to a module

- Writing word data to a host controller

- If a constant is specified in (s2), the instructions write the same data (the value in the device specified by (s2)) to the (n) words from the specified buffer memory address.
- Writing word data to a module

- Writing word data to a host controller

- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

## ■ DTO(P)

- This instruction writes the  $(n) \times 2$  points of data from the device specified by (s2) to the buffer memory address specified by (s1) and later in the buffer memory in the module or host controller specified by (U/H).
- Writing double word data to a module

- Writing double word data to a host controller

- If a constant is specified in (s2), the instructions write the same data (the value in the device specified by (s2)) to the  $(n) \times 2$  words from the specified buffer memory address.
- Writing double word data to a module

- Writing double word data to a host controller

- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |

(TO(P) instruction)<br>The 2×(n) points of data starting from the address specified by (s1) are outside the range of buffer memory. (DTO(P) instruction) |
| 3602H            | This instruction is executed for the intelligent module in an interrupt program with the priority 1 to 16.                                                                                                                                                                                                                                                                                                                  |

### Point

- If refresh settings are not made for the refresh area of the read/write enabled area in the CPU buffer memory, the area can be used as a read/write specifiable area. Even when refresh settings are made, the area can be used as a read/write specifiable area in the reference send range and later. If the intelligent module number U40\G0 or U42\G0 of the CC-Link IE TSN function part or motion function part is specified in the operand (U/H), the following range can be accessed.

- A CPU buffer memory access device can be used to write data to the CPU buffer memory. (📖 User's manual for the controller used)
- The TO(P) and DTO(P) instructions can write data to the buffer memory address with a capacity of 64K words or less. To write data to the buffer memory address with a capacity exceeding 64K words, use the TOD(P) or DTOD(P) instruction. (📖 Page 1021 TOD(P), DTOD(P))

# Reading 1-word/2-word data from another module (32-bit specification)

## FROMD(P), DFROMD(P)

- FROMD(P):

This instruction reads n words of data from the buffer memory address in the specified module.

- DFROMD(P):

This instruction reads n×2 words of data from the buffer memory address in the specified module.

\*1 Only the DFROMD(P) instruction can be used.

## Processing details

Specify the intelligent module numbers of the controller as shown in the table below.

| Controller                     | Intelligent module No. |
|--------------------------------|------------------------|
| CPU function part              | 3E0H                   |
| Built-in network function part | 40H                    |
| Built-in motion function part  | 42H                    |

### ■FROMD(P)

- This instruction reads (n) words of data from the buffer memory address specified by (s) in the module specified by (U/H), and stores in the device specified by (d) and later.

- If the read data (n) is 0, no processing is performed.
- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

### ■DFROMD(P)

- This instruction reads (n)×2 words of data from the buffer memory address specified by (s) in the module specified by (U/H), and stores in the device specified by (d) and later.

- If the read data (n) is 0, no processing is performed.
- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

## Operation error

| Error code (SD0) | Description                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | The module with the I/O number specified by (U) does not have buffer memory.                                                            |
|                  | The address specified by (s) is outside the range of CPU buffer memory.                                                                 |
|                  | The (n) points of data starting from the address specified by (s) are outside the range of CPU buffer memory. (FROMD(P) instruction)    |
|                  | The 2×(n) points of data starting from the address specified by (s) are outside the range of CPU buffer memory. (DFROMD(P) instruction) |
| 2823H            | The module with the I/O number specified by (H) does not have buffer memory.                                                            |
|                  | The address specified by (s) is outside the range of buffer memory.                                                                     |
|                  | The (n) points of data starting from the address specified by (s) are outside the range of buffer memory. (FROMD(P) instruction)        |
|                  | The 2×(n) points of data starting from the address specified by (s) are outside the range of buffer memory. (DFROMD(P) instruction)     |
| 3602H            | This instruction is executed for the intelligent module in an interrupt program with the priority 1 to 16.                              |

### Point

- If refresh settings are not made for the refresh area of the read/write enabled area in the CPU buffer memory, the area can be used as a read/write specifiable area. Even when refresh settings are made, the area can be used as a read/write specifiable area in the reference send range and later.
- A CPU buffer memory access device can be used to read data from the CPU buffer memory. ( User's manual for the controller used)
- The FROMD(P) and DFROMD(P) instructions can read data from the buffer memory address with a capacity exceeding 64K.

## Writing 1-word/2-word data to a module (32-bit specification)

### TOD(P), DTOD(P)

- TOD(P): This instruction writes the n points of data from the specified device to the buffer memory in the module.
- DTOD(P): This instruction writes the n×2 points of data from the specified device to the buffer memory in the module.

\*1 Only the DTOD(P) instruction can be used.

## Processing details

Specify the intelligent module numbers of the controller as shown in the table below.

| Controller                     | Intelligent module No. |
|--------------------------------|------------------------|
| CPU function part              | 3E0H                   |
| Built-in network function part | 40H                    |
| Built-in motion function part  | 42H                    |

### ■TOD(P)

- This instruction writes the *n* points of data from the device specified by (s2) to the buffer memory address specified by (s1) and later in the buffer memory in the module or host controller specified by (U/H).

- If a constant is specified in (s2), the instructions write the same data (the value in the device specified by (s2)) to the (n) words from the specified buffer memory address.

- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

## ■DTOD(P)

- This instruction writes the  $(n) \times 2$  points of data from the device specified by (s2) to the buffer memory address specified by (s1) and later in the buffer memory in the module or host controller specified by (U/H).

- If a constant is specified in (s2), the instructions write the same data (the value in the device specified by (s2)) to the  $(n) \times 2$  words from the specified buffer memory address.

- An instruction which has been executed will result in non-processing if it fails to access the target module because the module is faulty or busy in processing.

## Operation error

| Error code (SD0) | Description                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | The module with the I/O number specified by (U) does not have buffer memory.                                                                    |

\*1 For expansion adapters, "00: Normal" is always stored as there is no module-specific error status.

- The following table lists the module information of the CPU function part, built-in network function part, built-in motion function part, and built-in I/O function part inside the controller.

| Device | Bit       | Item name                                                                 | CPU function part (area 0)                     | Built-in network function part (area 1) | Built-in motion function part (area 2) | Built-in I/O function part (area 3)                        |

| 3602H            | This instruction was executed in an interrupt program with the priority 1 to 16 in a configuration that includes at least one intelligent module. |
| 36C5H            | Timeout occurred while communicating with modules during execution of the instruction.                                                            |
| 36C7H            | Signal error was detected while accessing modules during execution of the instruction.                                                            |

# 23 PID OPERATION INSTRUCTION

## PID operation instruction and PID control instruction

There are two types of instructions for PID control.

| Type                      | Application                                                                                               | Reference (Overview) | Reference (Details)                                                                                                |
|---------------------------|-----------------------------------------------------------------------------------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------|
| PID operation instruction | This instruction is used to perform PID control using auto tuning.                                        | Page 1029 Overview   | Page 1041 PID Operation Instruction                                                                                |
| PID control instruction   | This instruction is used to perform PID control equal to that of the MELSEC-Q series and MELSEC-L series. | Page 1045 Overview   | Page 1054 PID Control Instructions (Inexact Differential), Page 1066 PID Control Instructions (Exact Differential) |

The following table lists the specifications comparison between PID operation instruction and PID control instruction.

| Item                          | PID operation instruction                             | PID control instruction                 |
|-------------------------------|-------------------------------------------------------|-----------------------------------------|
| PID operation method          | Inexact differential                                  | Inexact differential/exact differential |
| Sampling period/sampling time | 1 to 32767ms                                          | 10 to 60000ms                           |
| Number of control loops       | 1 loop per instruction                                | 32 loops maximum                        |
| Auto tuning                   | Enabled (limit cycle method and step response method) | Disabled                                |

## 23.1 Overview

This section describes an overview of PID control using the PID operation instruction.

### PID operation instruction

The PID operation instruction calculates the manipulated value (MV) from the process value (PV) by combining the P action (proportional action), I action (integral action), and D action (derivative action) to get closer to the set value (SV).

#### ■Alarm output function

This function turns on the alarm output for the variations of input (process value) and output (manipulated value).

#### ■Output upper/lower limit value setting

This function suppresses the increase of integral terms in PID control by setting the output upper/lower limit values.

#### ■Auto tuning function

This function automatically sets the proportional gain ( $K_P$ ), integral time ( $T_I$ ), and derivative time ( $T_D$ ). The auto tuning is performed in two methods: limit cycle method and step response method.

#### ■Operation method of the PID operation instruction

The instruction performs PID operation in the velocity type or the process value derivative type.

## Basic operational expressions of PID operation instruction [Reference]

The instruction performs PID operation in the velocity type or the process value derivative type.

An operational expression of direct action or reverse action is executed depending on the value of bit 0 in the device specified by (s3)+1 (Action setting (ACT)).

The operation is performed using the control data stored in the device areas, (s3) and later.

- Operational expressions

| Action<br>(Bit 0 of (s3)+1) | Operational expression                                                                                                                                                                                                                                       |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Direct action<br>(Off)      | $\Delta MV = K_p \{ (EV_n - EV_{n-1}) + \frac{T_S}{T_I} EV_n + D_n \}$ $EV_n = PV_{nf} - SV$ $D_n = \frac{T_D}{T_S + K_D \cdot T_D} (-2PV_{nf-1} + PV_{nf} + PV_{nf-2}) + \frac{K_D \cdot T_D}{T_S + K_D \cdot T_D} \cdot D_{n-1}$ $MV_n = \Sigma \Delta MV$ |
| Reverse action<br>(On)      | $\Delta MV = K_p \{ (EV_n - EV_{n-1}) + \frac{T_S}{T_I} EV_n + D_n \}$ $EV_n = SV - PV_{nf}$ $D_n = \frac{T_D}{T_S + K_D \cdot T_D} (2PV_{nf-1} - PV_{nf} - PV_{nf-2}) + \frac{K_D \cdot T_D}{T_S + K_D \cdot T_D} \cdot D_{n-1}$ $MV_n = \Sigma \Delta MV$  |

The meaning of the symbols in the operational expressions is as follows.

| Symbol      | Meaning                                                                 |
|-------------|-------------------------------------------------------------------------|
| $EV_n$      | Deviation in the sampling period this time                              |
| $EV_{n-1}$  | Deviation in the sampling period last time                              |
| $SV$        | Set value                                                               |
| $PV_{nf}$   | Process value of the sampling period this time (after filtering)        |
| $PV_{nf-1}$ | Process value of the sampling period last time (after filtering)        |
| $PV_{nf-2}$ | Process value of the sampling period two times before (after filtering) |
| $\Delta MV$ | Output variation amount                                                 |
| $MV_n$      | Manipulated value this time                                             |
| $D_n$       | Derivative term this time                                               |
| $D_{n-1}$   | Derivative term of the sampling period last time                        |
| $K_p$       | Proportional gain                                                       |
| $T_S$       | Sampling period                                                         |
| $T_I$       | Integral constant                                                       |
| $T_D$       | Derivative constant                                                     |
| $K_D$       | Derivative gain                                                         |

$PV_{nf}$  (process value of the sampling period this time (after filtering)) is calculated by using the following operational expression. If the input filter coefficient is not set, the value will be the same as the input process value (PV).

$$PV_{nf} = PV_n + L(PV_{nf-1} - PV_n)$$

Where,  $PV_{nf}$ : Process value for the sampling period this time, L: Filter coefficient,  $PV_{nf-1}$ : Process value for the sampling period last time (after filtering)

## Control data

The details on the control data used by the PID operation instruction are described.

### Sampling time: (s3)

Setting range: 1 to 32767 [ms]

Set a cycle (ms) to perform PID operation.

- Auto tuning (limit cycle method)

Set a cycle so that the following condition is satisfied: Operation cycle of the programmable controller < Sampling time

- Auto tuning (step response method)

Set a cycle to 1000ms or longer.

### ■Maximum error

The maximum error of the sampling time ( $T_S$ ) is  $-(1 \text{ operation cycle} + 1\text{ms})$  to  $+(1 \text{ operation cycle})$ .

- When the sampling time ( $T_S$ ) value is small

The variation in the maximum error may become a problem. Set the constant scan and execute the instruction, or program it in the timer interrupt routine.

- When the sampling time value is shorter than one operation cycle of the programmable controller

A PID operation error (11A6H) occurs, but PID operation is executed assuming that the sampling time ( $T_S$ ) equals to the operation cycle. In this case, program the instruction in the timer interrupt routine, clear the value in (s3)+7, and then execute the instruction.

(1) Reset the value in (s3)+7. (The internal processing register is cleared by the pulse conversion command at the first execution of the interrupt routine.)

(2) Execute the PID operation.

## Action setting: (s3)+1

### ■Direction (direct action/reverse action): Bit 0 of (s3)+1

Setting range: Off = Direct action, On = Reverse action

Select the direction of PID control, direction action or reverse action.

- Auto tuning (limit cycle method)

The PID control direction must be set.

- Auto tuning (step response method)

At completion of auto tuning executed in whichever mode, direct action or reverse action, setting is made automatically.

[Direct action (bit 0 of (s3)+1 = Off)]

[Reverse action (bit 0 of (s3)+1 = On)]

### ■Alarm setting (input variation, output variation): Bit 1 and bit 2 of (s3)+1

Setting range: Off = Alarm disabled, On = Alarm enabled

The input and output variation amounts can be checked. The check result can be checked in (s3)+24. (Page 1038 Alarm output flag: (s3)+24)

- Input variation (bit 1 of (s3)+1)

To use the input variation alarm, the following bit needs to be on and the values need to be set to the following devices.

| Setting item                        |         |       | Description                                    | Setting range                |
|-------------------------------------|---------|-------|------------------------------------------------|------------------------------|
| Action setting (ACT)                | (s3)+1  | Bit 1 | Input variation alarm                          | On: Enabled<br>Off: Disabled |
| Input variation alarm setting value | (s3)+20 |       | Input variation (increase) alarm setting value | 0 to 32767                   |
|                                     | (s3)+21 |       | Input variation (decrease) alarm setting value |                              |

- Output variation (bit 2 of (s3)+1)

To use the output variation alarm, the following bits need to be on and the values need to be set to the following devices.

| Setting item                         |         |       | Description                                     | Setting range                |
|--------------------------------------|---------|-------|-------------------------------------------------|------------------------------|
| Action setting (ACT)                 | (s3)+1  | Bit 2 | Output variation alarm                          | On: Enabled<br>Off: Disabled |
|                                      |         | Bit 5 | Output upper/lower limit value setting          | Off (always)                 |
| Output variation alarm setting value | (s3)+22 |       | Output variation (increase) alarm setting value | 0 to 32767                   |
|                                      | (s3)+23 |       | Output variation (decrease) alarm setting value |                              |

■Output upper/lower limit value setting: Bit 5 of (s3)+1

The manipulated value (MV) will be as follows according to this setting.

MV: Manipulated value  
ULV: Output upper limit value  
LLV: Output lower limit value  
t: Time

This setting suppresses the increase of integral terms in PID control. To use this function, turn off the bit 2 of (s3)+1.

| Setting item         |        |       | Description                            | Setting range                |
|----------------------|--------|-------|----------------------------------------|------------------------------|
| Action setting (ACT) | (s3)+1 | Bit 2 | Output variation alarm                 | Off (always)                 |
|                      |        | Bit 5 | Output upper/lower limit value setting | On: Enabled<br>Off: Disabled |

## Input filter: (s3)+2

Setting range: 0 to 99 [%]

PID control: Proportional action, integral action, derivative action

The input filter ( $\alpha$ ) is a software filter used to reduce the variations caused by noise in the process value (PV). The influence of noise can be suppressed by setting the input filter ( $\alpha$ ) properly according to the characteristics and noise level of the control target.

- If the filter coefficient is too small, the effect will be reduced.
- If the filter coefficient is too large, the input response will deteriorate.

The input filter ( $\alpha$ ) acts on the set value (SV) and thus affects the proportional action, integral action, and derivative action.

Actual process  
value (PV)

Filtered process  
value (PV)

## Proportional gain: (s3)+3

Setting range: 1 to 32767 [%]

PID control: Proportional action

The manipulated value (MV) increases in proportion to the deviation (difference between the set value (SV) and the process value (PV)) in proportional operation. This ratio is called the proportional gain ( $K_P$ ) and represented by the following relational expression.

Manipulated value (MV) = Proportional gain ( $K_P$ ) × Deviation (EV)

The reciprocal of the proportional gain ( $K_P$ ) is called the proportional band.

As the proportional gain ( $K_P$ ) increases, the motion to get the process value (PV) closer to the set value (SV) becomes strong.

**Ex.**

Proportional action (P action) in the case of cooling (direct action)

Proportional gain ( $K_P$ ):  $K_{P3} > K_{P2} > K_{P1}$

°C: Temperature

SV: Set value

PV: Process value

MV: Manipulated value

t: Time

## Integral time: (s3)+4

Setting range: 0 to 32767 [ $\times 100\text{ms}$ ] ( $0 = \infty$ ) (No integration)

PID control: Integral action

The integral time ( $T_I$ ) is the time from when a deviation occurs in integral action to when the output of the integral action becomes the output of proportional action.

Reducing the integral time ( $T_I$ ) accelerates the integral operation.

**Ex.**

PI action in the case of cooling (direct action)

Integral time ( $T_I$ ):  $0 < T_{I3} < T_{I2} < T_{I1}$

°C: Temperature

SV: Set value

MV: Manipulated value

t: Time

## Derivative gain: (s3)+5

Setting range: 0 to 200 [%]

PID control: Derivative action

The output of the derivative action is filtered. The derivative gain ( $K_D$ ) affects only the derivative action.

- If the derivative gain ( $K_D$ ) is decreased, the output responds instantaneously to a change in the process value (PV) caused by a disturbance.
- If the derivative gain ( $K_D$ ) is increased, the output takes time to respond to a change in the process value (PV) caused by a disturbance.

**Point**

First, set the derivative gain ( $K_D$ ) to 0 and adjust it using the input filter ( $\alpha$ ). If the change in the output responds too sensitive to the disturbance, increase the value.

## Derivative time ( $T_D$ ): (s3)+6

Setting range: 0 to 32767 [ $\times 10\text{ms}$ ] (0 = no derivation)

PID control: Derivative action

The derivative time is used to be sensitive to the change in the process value (PV) caused by a disturbance and minimize the changes.

- Increasing the derivative time ( $T_D$ ) prevents more positively the control target from fluctuating due to a disturbance.

Derivative time ( $T_D$ ):  $T_{D3} > T_{D2} > T_{D1}$

EV: Deviation

MV: Manipulated value

t: Time

## Alarm output flag: (s3)+24

When the set input/output variation is exceeded, bits of (s3)+24 turn on as an alarm flag immediately after execution of the PID operation instruction.

- When the input variation alarm (bit 1 of (s3)+1) is on

PV: Process value  
 $T_s$ : Sampling time  
 t: Time  
 Bit 0 and bit 1 of (s3)+24: Alarm flag

- When the output variation alarm (bit 2 of (s3)+1) is on

MV: Manipulated value  
 $T_s$ : Sampling time  
 t: Time  
 Bit 2 and bit 3 of (s3)+24: Alarm flag

## Auto tuning

To obtain satisfactory results in PID control, it is required to determine the optimum values of each constant (control data) appropriate for the control target. The auto tuning function automatically sets the important constants for PID control, proportional gain, integral time, and derivative time.

The auto tuning function is performed in two methods: limit cycle method and step response method.

Start auto tuning after the system becomes stable. If not, auto tuning may not be performed correctly.

### Limit cycle method

#### ■Control data set by auto tuning (limit cycle method)

- Proportional gain ( $K_P$ ): (s3)+3
- Integral time ( $T_I$ ): (s3)+4
- Derivative time ( $T_D$ ): (s3)+6

#### ■Procedure

**1.** Set the action of PID operation.

Set the action (direct action or reverse action) with the bit 0 of (s3)+1 (Action setting (ACT)).

**2.** Select the limit cycle method.

Turn on the bit 6 of (s3)+1 (Action setting (ACT)).

(When the bit is off, the step response method is selected.)

**3.** Turn on the auto tuning execution flag.

Turn on the bit 4 of (s3)+1 (Action setting (ACT)).

**4.** Set an input filter constant.

Set a value in (s3)+2 (Input filter ( $\alpha$ )).

**5.** Set a sampling time.

Set a value in (s3)+0 (Sampling time ( $T_S$ )).

**6.** Set the output upper limit value (ULV).

Set the upper limit of the manipulated value (MV) in (s3)+26 (Output upper limit value (ULV)).

**7.** Set the output lower limit value (LLV).

Set the lower limit of the manipulated value (MV) in (s3)+27 (Output lower limit value (LLV)).

**8.** Set the PV value threshold (hysteresis) width (SHPV).

Set a value in (s3)+25 (PV value threshold (hysteresis) width (SHPV)).

**9.** Set a set value (SV).

Set a set value (SV) in (s1) of the PID operation instruction.

**10.** Start auto tuning.

Auto tuning starts based on the process value (PV) when the start contact device of the PID operation instruction turns on.

The auto tuning related flags (bit 4 and bit 6) of (s3)+1 (Action setting (ACT)) turn off upon completion of auto tuning.

## Step response method

### ■Control data set by auto tuning (step response method)

- Direction (direct action/reverse action): Bit 0 of (s3)+1
- Proportional gain ( $K_P$ ): (s3)+3
- Integral time ( $T_I$ ): (s3)+4
- Derivative time ( $T_D$ ): (s3)+6

### ■Procedure

#### 1. Set the output value for auto tuning.

Transfer the output value for auto tuning to the manipulated value (MV).

Set the output value for auto tuning to the "maximum allowable output value of the external device  $\times 0.5$  to 1".

#### 2. Set the data that is not set by auto tuning.

Set the following items, which are not set by auto tuning, depending on the system.

| Setting item |                           | Remarks                                                                               |
|--------------|---------------------------|---------------------------------------------------------------------------------------|
| (s1)         | Set value (SV)            | Set a value so that the difference from the process value (PV) becomes 150 or more.*1 |
| (s3)         | Sampling time ( $T_S$ )   | Set a cycle to 1000ms or longer.*2                                                    |
| (s3)+2       | Input filter ( $\alpha$ ) | —                                                                                     |
| (s3)+5       | Derivative gain ( $K_D$ ) | When the input filter is used, set the derivative gain to 0.                          |
| Others       |                           | Set other control data as needed.                                                     |

\*1 Difference between the set value (SV) and the process value (PV)

To perform auto tuning correctly, the difference between the process value (PV) and the set value (SV) must be 150 or more at the time of auto tuning start. If the difference is less than 150, set a set value (SV) for auto tuning.

After completion of auto tuning, set the SV back to the original value.

\*2 Sampling time ( $T_S$ ) setting

To perform auto tuning, set the sampling time ( $T_S$ ) to 1000ms or longer.

The sampling time should also be sufficiently longer than the output change period.

#### 3. Start auto tuning.

Turn on the bit 4 of (s3)+1 (Action setting (ACT)) to start auto tuning.

When the amount of variation from the process value (PV) at start of auto tuning to the set value (SV) becomes 1/3 or more, auto tuning is completed and the bit 4 of (s3)+1 (Action setting (ACT)) turns off automatically.

## Precautions

- Measures to be taken when the process value (PV) does not change

If the process value (PV) does not change properly due to an analog input disconnection or any other problems, auto tuning does not end. Detect and avoid such problems by creating a program that monitors the input value and the elapsed time from the start of auto tuning.

## 23.2 PID Operation Instruction

23

### PID

This instruction performs PID operation using the values set in (s1) to (s3), and stores the operation result in (d) at each cycle of sampling time.

#### Restriction

Before using the instruction, check the versions of the controller and engineering tool.

 User's manual for the controller used

| Ladder                                                                            | ST                       |
|-----------------------------------------------------------------------------------|--------------------------|
|  | ENO:=PID(EN,s1,s2,s3,d); |

| FBD/LD                                                                            |

### Processing details

When the set value (s1), process value (s2), and control data (s3) to (s3)+6 are set and a program is executed, the operation result, manipulated value (MV), is stored to (d) at every cycle of sampling time. For details, refer to the following.

 Page 1029 Overview

## ■Setting items (arguments)

| Setting item |                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Number of occupied points |

# 24 PID CONTROL INSTRUCTIONS

This instruction is for PID control.

## 24.1 Overview

This section describes the operation methods, procedures, and helpful functions of PID control by using PID control instructions.

### Point

The PID control instructions include those for inexact differential and exact differential.

Inexact differential is PID control that applies a primary delay filter to the input of a differentiation term, and is useful for the following.

- For control susceptible to high-frequency noise
- When energy effective to actuate an operation end is not provided when a step change occurs in an exact differential system

Exact differential is PID control that uses the input of a differential term as it is.

## Operation method

Two types of operation methods are available for PID control by using PID control instructions: velocity type and process value differentiation type.

The following table summarizes each operation methods.

| Operation method                   | Description                                                                                                                                                                                                                                                                 |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Velocity type                      | This type of control calculates variations in the manipulated values (MV) during PID operation. The actual MV is the accumulated value of variations calculated each sampling period.                                                                                       |
| Process value differentiation type | This type of control performs PID operation by differentiating the process value (PV). Since the deviation is not subject to differentiation, an abrupt change in output due to derivative action can be reduced when the deviation is generated by changing the set value. |

# PID control procedure

Create a program for PID control following the procedure below. (Devices are used in the procedure.)

- PID control data can be registered or changed every scan of the program. Whenever the data are registered or changed, execute the PIDINIT instruction. If not executed, the registered or changed data are not used when the PIDCONT instruction is executed.
- Note that the PIDINIT instruction does not need to be executed if the PID control data are changed for the specified loop by using the PIDPRMW instruction.

## PID control data

PID control data is used to set the reference values for PID operation. The set values need to be registered to the controller by using the PIDINIT instruction before PID operation by the PIDCONT instruction starts. The PID control data can be set to a word device area with any numbers. Note that all the data for the number of loops used must be set in the area with consecutive device numbers.

For data assignment, refer to the following.

- Inexact differential:  Page 1056 S(P).PIDINIT
- Exact differential:  Page 1068 PIDINIT(P)

PID control data are classified into two types: data common to all loops and data for each loop.

| Type                     | Item                                                    | Description                                                                                                                                                                                                                                                                                                    | Setting range                                              | Processing when set data is out of the valid range                                                                                                                                                                            |
|--------------------------|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data common to all loops | Number of loops used                                    | Number of loops where PID operation is performed                                                                                                                                                                                                                                                               | 1 to 32                                                    | An error occurs, and PID operation is not performed for all loops.                                                                                                                                                            |
|                          | Number of loops in one scan                             | Number of loops to be used in one PID operation when multiple loops reach the sampling period at a same time                                                                                                                                                                                                   | 1 to 32                                                    |                                                                                                                                                                                                                               |
| Data for each loop       | Operational expression selection                        | Selects direct action or reverse action.                                                                                                                                                                                                                                                                       | 0: Direct action<br>1: Reverse action                      | An error occurs, and PID operation is not performed for the corresponding loop.                                                                                                                                               |
|                          | Sampling period ( $T_S$ )                               | Sets a cycle of PID operation.                                                                                                                                                                                                                                                                                 | 1 to 6000 (in increments of 10ms)                          |                                                                                                                                                                                                                               |
|                          | Proportional constant ( $K_P$ )                         | A constant of proportionality in PID operation                                                                                                                                                                                                                                                                 | 1 to 10000 (in increments of 0.01)                         |                                                                                                                                                                                                                               |
|                          | Integral constant ( $T_I$ )                             | A constant that expresses the magnitude of the integral action effect. Increasing the integral constant slows down the variation in the manipulated value.                                                                                                                                                     | 1 to 32767 (in increments of 100ms)                        |                                                                                                                                                                                                                               |
|                          | Derivative constant ( $T_D$ )                           | A constant that expresses the magnitude of the derivative action effect. Increasing the derivative constant causes a significant change in the manipulated value even with slight change of the control objective.                                                                                             | 0 to 30000 (in increments of 10ms)                         |                                                                                                                                                                                                                               |
|                          | Filter coefficient ( $\alpha$ )                         | Degree of filtering applied to the process value (input value from the A/D converter module). The filtering effect decreases as the value gets closer to 0.                                                                                                                                                    | 1 to 100                                                   |                                                                                                                                                                                                                               |
|                          | Manipulated value lower limit (MVLL)                    | Lower limit of the manipulated value (MV) calculated by PID operation in automatic mode. If the MV is smaller than the MVLL, the MVLL is used as the MV.                                                                                                                                                       | -50 to 2050 <sup>*1</sup><br>-32768 to 32767 <sup>*2</sup> | In the case of *1, if the MVLL or MVHL value is out of the valid range, it will be converted as follows.<br>• If the value is smaller than -50, -50 is used.<br>• If the value is bigger than 2050, 2050 is used.             |
|                          | Manipulated value upper limit (MVHL)                    | Upper limit of the manipulated value (MV) calculated by PID operation in automatic mode. If the MV is bigger than the MVHL, the MVHL is used as the MV.                                                                                                                                                        | -50 to 2050 <sup>*1</sup><br>-32768 to 32767 <sup>*2</sup> |                                                                                                                                                                                                                               |
|                          | Manipulated value variation rate limit ( $\Delta MVL$ ) | Limit of variation in the manipulated values calculated last time and this time. If the variation exceeds the limit, 1 is set to b1 of the alarm device. Note that the variation amount will not be limited actually. Even if the variation exceeds the limit, it is used as it is, and the MV is calculated.  | 0 to 2000 <sup>*1</sup><br>0 to 32767 <sup>*2</sup>        | In the case of *1, if the $\Delta MVL$ or $\Delta PVL$ value is out of the valid range, it will be converted as follows.<br>• If the value is smaller than 0, 0 is used.<br>• If the value is bigger than 2000, 2000 is used. |
|                          | Process value variation rate limit ( $\Delta PVL$ )     | Limit of variation in the process values input last time and this time. If the variation exceeds the limit, 1 is set to b0 of the alarm device. Note that the variation amount will not be limited actually. Even if the variation exceeds the limit, it is used as it is, and the PID operation is performed. | 0 to 2000 <sup>*1</sup><br>0 to 32767 <sup>*2</sup>        |                                                                                                                                                                                                                               |
|                          | Derivative gain ( $K_D$ ) <sup>*3</sup>                 | A time period (operation delay) for derivative action. The time period decreases as the value gets bigger. (The operation becomes closer to exact differential.)                                                                                                                                               | 0 to 32767 (in increments of 0.01)                         |                                                                                                                                                                                                                               |

\*1 When the PID limit is restricted

\*2 When the PID limit is not restricted

\*3 For PID control (inexact differential) only

## ■Number of loops used and number of execution loops in one scan

The number of loops used is the number of loops where PID operation is performed. The sampling period is measured for the set number of loops when the PIDCONT instruction is executed, and PID operation is performed for the loops that reach the specified sampling period.

Processing time of the PIDCONT instruction increases in proportion to the number of loops where PID operation is performed. The number of execution loops in one scan is the number of loops where PID operation is performed in one scan when there are multiple loops that reach the specified sampling period. If this number is set, PID operation is performed only for the set number of loops, and PID operation for the rest of the loops that reach the sampling period will be performed in the next scan.

A: Time required to measure sampling period

B: Time required to perform PID operation for a single loop

n: Number of loops

### Point

When the number of loops that reach the sampling period exceeds the number of execution loops in one scan, the priority order will be as follows:

- The loop with the smallest loop number is given the highest priority.
- If there are loops where PID operation is performed and not performed in the last scan, the priority is given to the ones where PID operation is not performed in the last scan.

■Sampling period

Sampling period is a cycle in which PID operation is performed. The measurement time of a single scan is added to the total measurement time up to the last scan every time the PIDCONT instruction is executed. The total measurement time reaches or exceeds the set sampling period, PID operation of the corresponding loop is performed. Set the sampling period used in PID operation in increments of 10ms.

Ex.

When the sampling period is 50ms

PV: Measured value

SV: Set value

Restriction

Since the sampling period is measured at execution of the PIDCONT instruction, a value smaller than the program scan time cannot be set as the sampling period. If set, PID operation is performed with a scan time.

## I/O data

I/O data consists of input data, such as the set value (SV) and process value (PV), which are set to perform PID operation, and output data, such as operation results. The I/O data can be set to a word device area with any numbers. Note that all the data for the number of loops used must be set in the area with consecutive device numbers.

For data assignment, refer to the following.

- Inexact differential:  Page 1059 S(P).PIDCONT
- Exact differential:  Page 1070 PIDCONT(P)

The I/O data area is divided into two areas: data area assigned for each loop and work area used by the system.

| Item                          |                   | Description                                                                                                                                                                                                                                                                                                                                                                                         | Setting range                                                 | Remarks                                                                                                                                                                                                          |
|-------------------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Set value                     | SV                | A target value in PID control                                                                                                                                                                                                                                                                                                                                                                       | 0 to 2000 <sup>*1</sup>                                       | In the case of *1, if the SV is out of the valid range, it will be converted as follows.<br>• If the value is smaller than 0, 0 is used.<br>• If the value is bigger than 2000, 2000 is used.                    |
|                               |                   |                                                                                                                                                                                                                                                                                                                                                                                                     | -32768 to 32767 <sup>*2</sup>                                 |                                                                                                                                                                                                                  |
| Process value                 | PV                | A feedback data from the control target to the A/D converter module                                                                                                                                                                                                                                                                                                                                 | -50 to 2050 <sup>*1</sup>                                     | In the case of *1, if the PV is out of the valid range, it will be converted as follows.<br>• If the value is smaller than -50, -50 is used.<br>• If the value is bigger than 2050, 2050 is used.                |

\*1 When the PID limit is restricted

\*2 When the PID limit is not restricted

## Helpful functions

During PID operation by using PID control instructions, bumpless transfer and manipulated value upper/lower limit control are automatically executed.

### Bumpless transfer

This function controls the manipulated value (MV) continuously when the control mode is switched from manual to automatic, or vice-versa. When the mode is switched, data are transferred between the MV storage areas for manual mode and automatic mode.

- From manual to automatic: MV in manual mode is transferred to the MV storage area for automatic mode.
- From automatic to manual: MV in automatic mode is transferred to the MV storage area for manual mode.

Switch the mode in I/O data. (🔗 Page 1051 I/O data)

#### Point

PID control is performed in each mode as described below.

- Automatic mode: The controller controls the target with the MV calculated by PID operation using the PID control instructions.
- Manual mode: The controller controls the target with the MV calculated without performing PID operation using the PID control instructions. Loops set in manual mode stores the process value (PV) in the set value storage area every sampling cycle.

### Manipulated value upper/lower limits control

This function controls the upper or lower limit of the manipulated value (MV) calculated by PID operation. The function is only enabled in automatic mode and is not executed in manual mode.

The manipulated value (MV) calculated by PID operation can be limited within the range set by the manipulated value upper limit (MVHL) and manipulated value lower limit (MVLL). The following figure shows the operation of the function.

(1)  $MV_{AUTO}$  without limit control

The manipulated value upper limit (MVHL) and manipulated value lower limit (MVLL) can be set to each loop within the range of -50 to 2050 or within any desired range. The following values are set by default.

- Manipulated value upper limit: 2000
- Manipulated value lower limit: 0

An error occurs if the MVHL is smaller than the MVLL.

## Transferring PV to SV in manual mode

This function executes the PIDCONT instruction even in manual mode. In manual mode, whether transferring the process value (PV) input from the A/D converter module to the set value (SV) storage area during execution of the PIDCONT instruction or not can be selected by turning on or off SM792 or SM794. SM792 and SM794 are set to off by default. The PV and SV are stored in the specified device or label in the I/O data area by using the PIDCONT instruction.

| SM792, SM794 | Operation                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Off          | <ul style="list-style-type: none"> <li>The PV is transferred to the SV storage device or label during execution of the PIDCONT instruction.</li> <li>When the mode is switched to automatic mode, the MV output in manual mode is continued.</li> <li>If the SV is changed after the mode is switched to automatic mode, control from the MV output to the SV is enabled.</li> </ul> |
| On           | <ul style="list-style-type: none"> <li>The PV is not transferred to the SV storage device or label during execution of the PIDCONT instruction.</li> <li>When the mode is switched to automatic mode, control from the MV output in manual mode to the SV is enabled.</li> <li>Before switching to automatic mode, store the SV to the SV storage device or label.</li> </ul>        |

### Point

Depending on the on/off status of SM792 or SM794, the following differences apply when switching manual mode to automatic mode.

- When SM792 or SM794 is off, the PV is transferred to the SV storage device or label. Therefore, there is no difference between the PV and SV and an abrupt change does not occur in MV when the mode is switched. Note, however, that since the SV after the mode is switched differs from the target value in automatic mode, the user needs to change the SV step by step in the program so that it matches the target value.
- When SM792 or SM794 is on, the PV is not transferred to the SV storage device or label. Therefore, a difference exists between the PV and SV when the mode is switched. If the difference is large when the mode is switched, an abrupt change may occur in MV. Use this method in a system where the mode is switched when the PV has fully neared the SV. PID control in automatic mode can be executed immediately without the SV being changed step by step in the program.

## Changing the setting range of PID control data and I/O data

The setting range of PID control data and I/O data can be changed as desired.

To change the range, turn on the bit corresponding to the target loop in SD792, SD793, SD794, and SD795.

| Inexact differential | Exact differential | Operation                                                                                                                                                                                                                                                                                                                                                           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

1: PID limit not restricted

# 24.2 PID Control Instructions (Inexact Differential)

Inexact differential is PID control that applies a primary delay filter to the input of a differentiation term. Inexact differential is effective in the following cases:

- For control susceptible to high-frequency noise
- When energy effective to actuate an operation end is not provided when a step change occurs in an exact differential system

The following table summarizes the performance specifications of PID control instructions for inexact differential.

| Item                           |                       | When the PID limit is restricted | When the PID limit is not restricted                                                     |
|--------------------------------|-----------------------|----------------------------------|------------------------------------------------------------------------------------------|

The following are the block diagram and operational expressions of PID operation.

- Block diagram of PID operation (inexact differential)

$K_P$ : Gain  
 $W$ : Disturbance  
 $P$ : Controlled system  
 $V$ : Detected noise

• Operational expressions

| Action         | Operational expression                                                                                                                                                                                                                                                   |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Direct action  | $EV_n = PV_{fn} - SV$ $\Delta MV = K_p \{ (EV_n - EV_{n-1}) + \frac{T_s}{T_i} \cdot EV_n + D_n \}$ $D_n = \frac{T_D}{T_s + \frac{T_D}{K_D}} (PV_{fn} - 2PV_{fn-1} + PV_{fn-2}) + \frac{\frac{T_D}{K_D}}{T_s + \frac{T_D}{K_D}} \cdot D_{n-1}$ $MV_n = \Sigma \Delta MV$  |
| Reverse action | $EV_n = SV - PV_{fn}$ $\Delta MV = K_p \{ (EV_n - EV_{n-1}) + \frac{T_s}{T_i} \cdot EV_n + D_n \}$ $D_n = \frac{T_D}{T_s + \frac{T_D}{K_D}} (-PV_{fn} + 2PV_{fn-1} - PV_{fn-2}) + \frac{\frac{T_D}{K_D}}{T_s + \frac{T_D}{K_D}} \cdot D_{n-1}$ $MV_n = \Sigma \Delta MV$ |

The meaning of the symbols in the operational expressions is as follows.

| Symbol      | Meaning                                                                 |
|-------------|-------------------------------------------------------------------------|
| $EV_n$      | Deviation in the sampling period this time                              |
| $EV_{n-1}$  | Deviation in the sampling period last time                              |
| $SV$        | Set value                                                               |
| $PV_{fn}$   | Process value of the sampling period this time (after filtering)        |
| $PV_{fn-1}$ | Process value of the sampling period last time (after filtering)        |
| $PV_{fn-2}$ | Process value of the sampling period second last time (after filtering) |
| $\Delta MV$ | Output variation amount                                                 |
| $MV_n$      | Manipulated value this time                                             |
| $D_n$       | Derivative term this time                                               |
| $D_{n-1}$   | Derivative term of the sampling period last time                        |
| $T_s$       | Sampling period                                                         |
| $K_p$       | Proportional constant                                                   |
| $T_i$       | Integral constant                                                       |
| $T_D$       | Derivative constant                                                     |
| $K_D$       | Derivative gain                                                         |

The  $PV_{fn}$  is calculated by using the following operational expression. If the input filter coefficient is not set, the value will be the same as the input process value (PV).

$$PV_{fn} = PV_n + \alpha(PV_{fn-1} - PV_n)$$

$PV_n$ : Process value for the sampling period this time,  $\alpha$ : Filter coefficient,  $PV_{fn-1}$ : Process value for the sampling period last time (after filtering)

$PV_{fn}$  is stored in the I/O data area. (☞ Page 1051 I/O data)

# Registering the PID control data to the controller

## S(P).PIDINIT

These instructions store the PID control data by the number of loops used that is set in the specified device number and later altogether in the controller module.

| Ladder | ST                                                      |
|--------|---------------------------------------------------------|
|        | <pre>ENO:=S_PIDINIT(EN,s); ENO:=SP_PIDINIT(EN,s);</pre> |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|

\*1  $m = (n-1) \times 14 + 2$

(1) Fixed to "0". An error results if a value other than "0" is specified.

- The number of device points used for PID control data setting is calculated by the following formula.

Number of device points =  $2 + 14 \times n$  (n: number of loops used)

- Specify each data in binary.
- If the total number of device points for the number of loops used exceeds the last device number, an error occurs and no processing is performed.
- If the S(P).PIDINIT instruction is executed at two or more locations during a single scan, the setting value of the S(P).PIDINIT instruction executed nearest to the S(P).PIDCONT instruction will be valid.
- Execute the S(P).PIDINIT instruction before execution of the S(P).PIDCONT instruction. To perform PID control, the S(P).PIDINIT instruction must be executed.

## Operation error

## Performing PID operation

### S(P).PIDCONT

These instructions measure the sampling cycle and perform PID operation when the execution command turns on.

| Ladder                                                                            | ST                                                      |
|-----------------------------------------------------------------------------------|---------------------------------------------------------|
|  | <pre>ENO:=S_PIDCONT(EN,s); ENO:=SP_PIDCONT(EN,s);</pre> |

## Processing details

- The S(P).PIDCONT instructions measure the sampling cycle and perform PID operation.
- Based on the setting value (SV) and process value (PV) in the I/O data area allocated to the device number specified by (s) and later, these instructions perform PID operation and store the operation result in the automatic manipulated value (MV) area in the I/O data area.
- The S(P).PIDCONT instructions perform PID operation when it is executed for the first time after a lapse of the specified sampling cycle.
- During PID control, be sure to turn on the control command to allow the S(P).PIDCONT instruction to be executed every scan. Failure to execute the instruction every scan disables PID operation in normal sampling cycles. The S(P).PIDCONT instruction cannot be executed more than once in a single scan. Executing the instruction more than once in a single scan disables PID operation in normal sampling cycles.
- The S(P).PIDCONT instruction cannot be written and used in interrupt programs. Writing an S(P).PIDCONT instruction in the interrupt program disables PID operation in normal sampling cycles.
- In (s), specify the head of the device number specified in the I/O data area. (  Page 1051 I/O data)
- If a file register is specified as an I/O data area, do not apply memory protection for the file register. If memory protection is applied, normal PID operation is disabled although no error results.
- The I/O data are assigned as follows.

| Item                                                       |                     | I/O data   |                                                |

|                                                            | Read/write disabled | (s)+(m+7)  | Work area for loop No.n<br>(system use only)   |
|                                                            |                     | ⋮          |                                                |
|                                                            |                     | (s)+(m+22) |                                                |

\*1  $m = (n-1) \times 23 + 10$

- The number of device points used for I/O data setting is calculated by the following formula.

Number of device points =  $10 + 23 \times n$  (n: number of loops used)

- Specify each data in binary.
- The initial processing flag sets the processing to be performed at the start of PID operation.
  - Initial operation processing is performed assuming that the sampling cycle that has been set has been reached.
  - If the initial processing flag is 0, PID operations for the number of loops used are performed altogether in a single scan. If it is not 0, PID operations for the number of loops used are divided and processed in several scans, and sampling is started sequentially from the loop that has completed initial processing. The number of processing loops per scan is the number of execution loops per scan that has been set.

- Write data to the I/O data "Write" area by users with the program. Users can read data from the I/O data "Read" area with the program. Never attempt to write data to the area indicated by "Read/write disabled" or "Read"; otherwise, normal operation can no longer be performed. Note that, when starting control from the initial status, the data areas must be cleared by the program.
- If the total number of device points for the number of loops used exceeds the last device number, an error occurs and no processing is performed.
- Even when the manual manipulated value ( $MV_{MAN}$ ) is output in manual mode, execute the S(P).PIDCONT instruction every scan. Unless the S(P).PIDCONT instruction is executed, the bumpless function cannot be performed.
- Apply an interlock using the READY signal of each module so that the S(P).PIDCONT instruction is executed only when the A/D converter module used to obtain the process value (PV) and the D/A converter module used to output the manipulated value (MV) are normal.

- (1) Control command  
 (2) READY signal of the A/D converter module  
 (3) READY signal of the D/A converter module

If the instruction is executed when these modules are not normal, PID operation cannot be performed normally as the result of failure in normal acquisition of process values (PV) or in normal output of manipulated values (MV).

## Operation error

### Processing details

- These instructions stop the PID operation of the loop number in the device specified by (s). The loop stopped by the S(P).PIDSTOP instruction does not restart PID operation even if the S(P).PIDINIT instruction is executed.
- Each instruction holds operation data while the loop is stopped.

### Operation error

# 24.3 PID Control Instructions (Exact Differential)

Exact differential is PID control that uses the input of a differential term as it is.

The following table summarizes the performance specifications of PID control instructions for exact differential.

| Item                           |                       | When the PID limit is restricted | When the PID limit is not restricted                                                   |
|--------------------------------|-----------------------|----------------------------------|----------------------------------------------------------------------------------------|
| Number of PID control loops    |                       | —                                | 32 maximum                                                                             |
| Sampling period                |                       | $T_S$                            | 0.01 to 60.00s                                                                         |
| PID operation method           |                       | —                                | Process value differentiation type (exact differential) (direct action/reverse action) |
| PID constants setting range    | Proportional constant | $K_P$                            | 0.01 to 100.00                                                                         |

The following are the block diagram and operational expressions of PID operation.

- Block diagram of PID operation (exact differential)

$K_P$ : Gain  
 $W$ : Disturbance  
 $P$ : Controlled system  
 $V$ : Detected noise

• Operational expressions

| Action         | Operational expression                                                                                                                                                                              |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Direct action  | $EV_n = PV_{fn} - SV$ $\Delta MV = K_p \left\{ (EV_n - EV_{n-1}) + \frac{T_s}{T_i} \cdot EV_n + D_n \right\}$ $D_n = \frac{T_D}{T_s} (PV_{fn} - 2PV_{fn-1} + PV_{fn-2})$ $MV_n = \Sigma \Delta MV$  |
| Reverse action | $EV_n = SV - PV_{fn}$ $\Delta MV = K_p \left\{ (EV_n - EV_{n-1}) + \frac{T_s}{T_i} \cdot EV_n + D_n \right\}$ $D_n = \frac{T_D}{T_s} (-PV_{fn} + 2PV_{fn-1} - PV_{fn-2})$ $MV_n = \Sigma \Delta MV$ |

The meaning of the symbols in the operational expressions is as follows.

| Symbol      | Meaning                                                                 |
|-------------|-------------------------------------------------------------------------|
| $EV_n$      | Deviation in the sampling period this time                              |
| $EV_{n-1}$  | Deviation in the sampling period last time                              |
| $SV$        | Set value                                                               |
| $PV_{fn}$   | Process value of the sampling period this time (after filtering)        |
| $PV_{fn-1}$ | Process value of the sampling period last time (after filtering)        |
| $PV_{fn-2}$ | Process value of the sampling period second last time (after filtering) |
| $\Delta MV$ | Output variation amount                                                 |
| $MV_n$      | Manipulated value this time                                             |
| $D_n$       | Derivative term this time                                               |
| $T_s$       | Sampling period                                                         |
| $K_p$       | Proportional constant                                                   |
| $T_i$       | Integral constant                                                       |
| $T_D$       | Derivative constant                                                     |

The  $PV_{fn}$  is calculated by using the following operational expression. If the input filter coefficient is not set, the value will be the same as the input process value (PV).

$$PV_{fn} = PV_n + \alpha(PV_{fn-1} - PV_n)$$

$PV_n$ : Process value for the sampling period this time,  $\alpha$ : Filter coefficient,  $PV_{fn-1}$ : Process value for the sampling period last time (after filtering)

$PV_{fn}$  is stored in the I/O data area. (  Page 1051 I/O data)

# Registering the PID control data to the controller

## PIDINIT(P)

These instructions store the PID control data by the number of loops used that is set in the specified device number and later altogether in the controller module.

| Ladder                                                                            | ST                                                  |

|                                        | (s)+(m+9)        | Process value variation rate limit ( $\Delta$ PVL)     |

\*1  $m = (n-1) \times 10 + 2$

- The number of device points used for PID control data setting is calculated by the following formula.

Number of device points =  $2 + 10 \times n$  (n: number of loops used)

- Specify each data in binary.
- If the total number of device points for the number of loops used exceeds the last device number, an error occurs and no processing is performed.
- If the PIDINIT(P) instruction is executed at two or more locations during a single scan, the setting value of the PIDINIT(P) instruction executed nearest to the PIDCONT(P) instruction will be valid.
- Execute the PIDINIT(P) instruction before execution of the PIDCONT(P) instruction. To perform PID control, the PIDINIT(P) instruction must be executed.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                            |

## Processing details

- The PIDCONT(P) instructions measure the sampling cycle and perform PID operation.
- Based on the setting value (SV) and process value (PV) in the I/O data area allocated to the device number specified by (s) and later, these instructions perform PID operation and store the operation result in the automatic manipulated value (MV) area in the I/O data area.
- The PIDCONT(P) instructions perform PID operation when it is executed for the first time after a lapse of the specified sampling cycle.
- During PID control, be sure to turn on the control command to allow the PIDCONT(P) instruction to be executed every scan. Failure to execute the instruction every scan disables PID operation in normal sampling cycles. The PIDCONT(P) instruction cannot be executed more than once in a single scan. Executing the instruction more than once in a single scan disables PID operation in normal sampling cycles.
- The PIDCONT(P) instruction cannot be written and used in interrupt programs. Writing a PIDCONT(P) instruction in the interrupt program disables PID operation in normal sampling cycles.
- In (s), specify the head of the device number specified in the I/O data area. (  Page 1051 I/O data)
- If a file register is specified as an I/O data area, do not apply memory protection for the file register. If memory protection is applied, normal PID operation is disabled although no error results.
- The I/O data are assigned as follows.

| Item                                                       |                     | I/O data   |                                                |

\*1  $m = (n-1) \times 18 + 10$

- The number of device points used for I/O data setting is calculated by the following formula.

Number of device points =  $10 + 18 \times n$  (n: number of loops used)

- Specify each data in binary.
- The initial processing flag sets the processing to be performed at the start of PID operation.
  - Initial operation processing is performed assuming that the sampling cycle that has been set has been reached.
  - If the initial processing flag is 0, PID operations for the number of loops used are performed altogether in a single scan. If it is not 0, PID operations for the number of loops used are divided and processed in several scans, and sampling is started sequentially from the loop that has completed initial processing. The number of processing loops per scan is the number of execution loops per scan that has been set.

- Write data to the I/O data "Write" area by users with the program. Users can read data from the I/O data "Read" area with the program. Never attempt to write data to the area indicated by "Read/write disabled" or "Read"; otherwise, normal operation can no longer be performed. Note that, when starting control from the initial status, the data areas must be cleared by the program.
- Even when the manual manipulated value ( $MV_{MAN}$ ) is output in manual mode, execute the PIDCONT(P) instruction every scan. Unless the PIDCONT(P) instruction is executed, the bumpless function cannot be performed.
- Apply an interlock using the READY signal of each module so that the PIDCONT(P) instruction is executed only when the A/D converter module used to obtain the process value (PV) and the D/A converter module used to output the manipulated value (MV) are normal. If the instruction is executed when these modules are not normal, PID operation cannot be performed normally as the result of failure in normal acquisition of process values (PV) or in normal output of manipulated values (MV).

- (1) Control command  
 (2) READY signal of the A/D converter module  
 (3) READY signal of the D/A converter module

### Processing details

- These instructions stop the PID operation of the loop number in the device specified by (s). The loop stopped by the PIDSTOP(P) instruction does not restart PID operation even if the PIDINIT(P) instruction is executed.
- Each instruction holds operation data while the loop is stopped.

### Processing details

- These instructions start the PID operation of the loop number in the device specified by (s). These instructions are used to re-execute the PID operation of the loop number that has been stopped by the PIDSTOP(P) instruction.
- The PIDRUN(P) instruction, if executed for a loop number already in progress of PID operation, performs no processing.

### Operation error

| Error code (SD0) | Description                                                                                                                                                                                           |

## Processing details

- These instructions changes the operation parameter of the loop number in the device specified by (s1) to the PID control data stored in the device number specified by (s2) and later.
- The following figure shows the configuration of the PID control data in the device specified by (s2) and later.

| PID control data |                                                         |
|------------------|---------------------------------------------------------|
| (s2)+0           | Operational expression selection                        |
| (s2)+1           | Sampling period ( $T_S$ )                               |
| (s2)+2           | Proportional constant ( $K_P$ )                         |
| (s2)+3           | Integral constant ( $T_I$ )                             |
| (s2)+4           | Derivative constant ( $T_D$ )                           |
| (s2)+5           | Filter coefficient ( $\alpha$ )                         |
| (s2)+6           | Manipulated value lower limit (MVLL)                    |
| (s2)+7           | Manipulated value upper limit (MVHL)                    |
| (s2)+8           | Manipulated value variation rate limit ( $\Delta MVL$ ) |
| (s2)+9           | Process value variation rate limit ( $\Delta PVL$ )     |

## Operation error

| Error code (SD0) | Description                                                                                                                                          |

# 25 HIGH-SPEED I/O CONTROL INSTRUCTIONS

25

## 25.1 Start/Stop of High-Speed I/O

### Start/stop of the 16-bit data high-speed I/O function

#### HIOEN(P)

These instructions control the start and stop operations of a high-speed I/O function.

| Ladder                                                                            | Structured text                                       |

## Processing details

Specify the number of the function to be started or stopped in (s1), the bit of the channel to be started in (s2), and the bit of the channel to be stopped in (s3).

The following table lists the function numbers which can be specified in (s1).

### ■Function number

| Function number   | Function name                                               |
|-------------------|-------------------------------------------------------------|
| K0                | High-speed counter                                          |
| K10 <sup>*1</sup> | Pulse density/rotation speed measurement                    |
| K20 <sup>*1</sup> | High-speed comparison table (controller)                    |
| K21 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 1) |
| K22 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 2) |
| K23 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 3) |
| K24 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 4) |
| K40               | Pulse width measurement                                     |
| K50               | PWM                                                         |

<sup>\*1</sup> When high-speed counter (function number: K0) is stopped during function operation, the function continues to operate, but nothing will be processed.

The following table lists the values which can be specified in (s2) and (s3) for each function number.

- Function number K0

The counting start and stop of a high-speed counter can be controlled for each channel of high-speed counter.

CH1 to CH8 are assigned to controllers, and CH9 to CH16 are assigned to high-speed pulse I/O modules, as shown below.

| Bit position |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14  | b13  | b12  | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| CH16         | CH15 | CH14 | CH13 | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

#### Ex.

To start CH3, set 04H in (s2). To stop it, set 04H in (s3).

To start CH1, CH4, and CH5, set 19H in (s2). To stop them, set 19H in (s3).

To start CH1 and CH4 and to stop CH5, set 09H in (s2) and set 10H in (s3).

- Function number K10

The measuring start and stop of the pulse density (rotation speed measurement) can be controlled for each channel of the high-speed counter. Turn off b8 to b15.

| Bit position |     |     |     |     |     |    |    |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|-----|-----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            | —   | —   | —   | —   | —   | —  | —  | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

- Function numbers K20 to K24

Set the value to turn on the bit of the high-speed comparison table number which is to be started or stopped.

For the controller (K20), b0 to b15 can be used.

For the high-speed pulse input/output modules (K21 to K24), b0 to b14 can be used.

| Bit position |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14  | b13  | b12  | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| CH16         | CH15 | CH14 | CH13 | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

- Function numbers K40 and K50

The measuring start and stop of pulse width measurement and PWM can be controlled for each channel. Ignore unused bits.

CH1 to CH4 are assigned to controllers, and CH5 to CH12 are assigned to high-speed pulse I/O modules, as shown below.

| Bit position |     |     |     |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            | —   | —   | —   | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

## Precautions

- Do not specify channel numbers of the high-speed pulse input/output module in a program with interrupt priority set to 1.
- When values that turn on the same channel are set for start and stop, the stop operation is prioritized.
- If the high-speed counter (function number: K0) is stopped when the pulse density (function number: K10) or high-speed comparison table (function number: K20 to K24) is executed by the HIOEN instruction, no processing is performed even though the function is in operation.
- If there is a channel where an error occurs (error code: 3781H) when the high-speed counter (function number: K0) is executed by the HIOEN instruction, the counter can no longer be started/stopped for the applicable channel and subsequent channels.
- When using the high-speed comparison table (function number: K20) with the HIOEN instruction, set the number of simultaneous high-speed comparisons (the number of tables specified by the HIOEN instruction + the number of channels for which the high-speed mode of input interrupt signal 1 is selected in the positioning parameter setting) within 32 times.
- When using the high-speed comparison table (function number: K21 to K24) with the HIOEN instruction, set the number of simultaneous high-speed comparisons (the number of tables specified by the HIOEN instruction + the number of channels for which the high-speed mode of input interrupt signal 1 is selected + the number of channels for which OPR (zero signal) is selected in the positioning parameter setting + the number of channels for which OPR (clear signal) is selected in the positioning parameter setting) within 15 times.
- To start the high-speed comparison table (function number: K20 to K24), the high-speed counter must be started using the HIOEN instruction in advance.
- When the high-speed counter (function number: K0) is used, input pulses to the channel to be started after the HIOEN instruction is complete. If pulses are input before the HIOEN instruction is complete, they may be lost.
- The high-speed input/output instructions operate according to the following parameters.

| Function number | Function specified by the HIOEN instruction                 | Parameter setting                                                                     |
|-----------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------|
| K0              | High-speed counter                                          | Channel setting of the high-speed counter                                             |
| K10             | Pulse density (rotation speed measurement)                  | Channel setting of the pulse density/rotation speed measurement<br>High-speed counter |
| K20             | High-speed comparison table (controller)                    | Output setting of the high-speed counter                                              |
| K21             | High-speed comparison table (high-speed pulse I/O module 1) |                                                                                       |
| K22             | High-speed comparison table (high-speed pulse I/O module 2) |                                                                                       |
| K23             | High-speed comparison table (high-speed pulse I/O module 3) |                                                                                       |
| K24             | High-speed comparison table (high-speed pulse I/O module 4) |                                                                                       |
| K40             | Pulse width measurement                                     | Channel setting of the pulse width measurement                                        |
| K50             | PWM                                                         | Channel setting of PWM                                                                |

## Operation error

| Error code (SD0) | Description                                                                                                                                                                    |

| 1810H            | Channel number which is used in another instruction is specified.                                                                                                              |
| 2801H            | The channel number of a module that does not exist is specified.                                                                                                               |
| 36C5H            | Timeout occurred while communicating with the target modules during execution of the instruction.                                                                              |
| 36C7H            | Signal error was detected while accessing the target modules during execution of the instruction.                                                                              |
| 3285H            | An invalid function number is specified in (s).                                                                                                                                |
| 3600H            | A channel number which is not selected in the parameter setting is executed.                                                                                                   |
| 3602H            | Counting of the high-speed I/O module counter, pulse width measurement, or PWM starts/stops by the HIOEN instruction at interrupt priorities 1 to 16 of the interrupt program. |
| 3781H            | Ring length $\leq$ preset value is specified and executed in channel for which ring length is set and preset input is enabled.                                                 |

# Start/stop of the 32-bit data high-speed I/O function

## DHIOEN(P)

These instructions control the start and stop operations of a high-speed I/O function.

| Ladder | Structured text                                                 |

## Processing details

Specify the number of the function to be started or stopped in (s1), the bit of the channel to be started in (s2), and the bit of the channel to be stopped in (s3).

The following table lists the function numbers which can be specified in (s1).

### ■Function number

| Function number   | Function name                                               |
|-------------------|-------------------------------------------------------------|
| K0                | High-speed counter                                          |
| K10 <sup>*1</sup> | Pulse density/rotation speed measurement                    |
| K20 <sup>*1</sup> | High-speed comparison table (controller)                    |
| K21 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 1) |
| K22 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 2) |
| K23 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 3) |
| K24 <sup>*1</sup> | High-speed comparison table (high-speed pulse I/O module 4) |
| K40               | Pulse width measurement                                     |
| K50               | PWM                                                         |

\*1 When high-speed counter (function number: K0) is stopped during function operation, the function continues to operate, but nothing will be processed.

The following table lists the values which can be specified in (s2) and (s3) for each function number.

- Function number K0

The counting start and stop of a high-speed counter can be controlled for each channel of high-speed counter.

CH1 to CH8 are assigned to controllers, and CH9 to CH16 are assigned to high-speed pulse I/O modules, as shown below.

| Bit position |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14  | b13  | b12  | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| CH16         | CH15 | CH14 | CH13 | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

#### Ex.

To start CH3, set 04H in (s2). To stop it, set 04H in (s3).

To start CH1, CH4, and CH5, set 19H in (s2). To stop them, set 19H in (s3).

To start CH1 and CH4 and to stop CH5, set 09H in (s2) and set 10H in (s3).

- Function number K10

The measuring start and stop of the pulse density (rotation speed measurement) can be controlled for each channel of the high-speed counter. Turn off b8 to b15.

| Bit position |     |     |     |     |     |    |    |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|-----|-----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            | —   | —   | —   | —   | —   | —  | —  | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

- Function numbers K20 to K24

Set the value to turn on the bit of the high-speed comparison table number which is to be started or stopped.

For the controller (K20), b0 to b31 can be used.

For the high-speed pulse input/output modules (K21 to K24), b0 to b14 can be used.

| Low-order bit position |      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |
|------------------------|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15                    | b14  | b13  | b12  | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| CH16                   | CH15 | CH14 | CH13 | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

| High-order bit position |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|-------------------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| b31                     | b30  | b29  | b28  | b27  | b26  | b25  | b24  | b23  | b22  | b21  | b20  | b19  | b18  | b17  | b16  |
| CH32                    | CH31 | CH30 | CH29 | CH28 | CH27 | CH26 | CH25 | CH24 | CH23 | CH22 | CH21 | CH20 | CH19 | CH18 | CH17 |

- Function numbers K40 and K50

The measuring start and stop of pulse width measurement and PWM can be controlled for each channel. Ignore unused bits. CH1 to CH4 are assigned to controllers, and CH5 to CH12 are assigned to high-speed pulse I/O modules, as shown below.

| Bit position |     |     |     |      |      |      |     |     |     |     |     |     |     |     |     |
|--------------|-----|-----|-----|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b15          | b14 | b13 | b12 | b11  | b10  | b9   | b8  | b7  | b6  | b5  | b4  | b3  | b2  | b1  | b0  |
| —            |     |     |     | CH12 | CH11 | CH10 | CH9 | CH8 | CH7 | CH6 | CH5 | CH4 | CH3 | CH2 | CH1 |

## Precautions

- Do not specify channel numbers of the high-speed pulse input/output module in a program with interrupt priority set to "1".
- When values that turn on the same channel are set for start and stop, the stop operation is prioritized.
- If the high-speed counter (function number: K0) is stopped when the pulse density (function number: K10) or high-speed comparison table (function number: K20 to K24) is executed by the HIOEN instruction, no processing is performed even though the function is in operation.
- If there is a channel where an error occurs (error code: 3781H) when the high-speed counter (function number: K0) is executed by the DHIOEN instruction, the counter can no longer be started/stopped for the applicable channel and subsequent channels.
- When using the high-speed comparison table (function number: K20) with the HIOEN instruction, set the number of simultaneous high-speed comparisons (the number of tables specified by the HIOEN instruction + the number of channels for which the high-speed mode of input interrupt signal 1 is selected in the positioning parameter setting) within 32 times.
- When using the high-speed comparison table (function number: K21 to K24) with the HIOEN instruction, set the number of simultaneous high-speed comparisons (the number of tables specified by the HIOEN instruction + the number of channels for which the high-speed mode of input interrupt signal 1 is selected + the number of channels for which OPR (zero signal) is selected in the positioning parameter setting + the number of channels for which OPR (clear signal) is selected in the positioning parameter setting) within 15 times.
- To start the high-speed comparison table (function number: K20 to K24), the high-speed counter must be started using the HIOEN instruction in advance.
- When the high-speed counter (function number: K0) is used, input pulses to the channel to be started after the DHIOEN instruction is complete. If pulses are input before the DHIOEN instruction is complete, they may be lost.
- The high-speed input/output instructions operate according to the following parameters.

| Function number | Function specified by the HIOEN instruction                 | Parameter setting                                                                     |
|-----------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------|
| K0              | High-speed counter                                          | Channel setting of the high-speed counter                                             |
| K10             | Pulse density (rotation speed measurement)                  | Channel setting of the pulse density/rotation speed measurement<br>High-speed counter |
| K20             | High-speed comparison table (controller)                    | Output setting of the high-speed counter                                              |
| K21             | High-speed comparison table (high-speed pulse I/O module 1) |                                                                                       |
| K22             | High-speed comparison table (high-speed pulse I/O module 2) |                                                                                       |
| K23             | High-speed comparison table (high-speed pulse I/O module 3) |                                                                                       |
| K24             | High-speed comparison table (high-speed pulse I/O module 4) |                                                                                       |
| K40             | Pulse width measurement                                     | Channel setting of the pulse width measurement                                        |
| K50             | PWM                                                         | Channel setting of PWM                                                                |

## Operation error

| Error code(SD0) | Description                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1810H           | Channel number which is used in another instruction is specified.                                                                                                              |
| 2801H           | The channel number of a module that does not exist is specified.                                                                                                               |
| 36C5H           | Timeout occurred while communicating with the target modules during execution of the instruction.                                                                              |
| 36C7H           | Signal error was detected while accessing the target modules during execution of the instruction.                                                                              |

| 3600H           | A channel number which is not selected in the parameter setting is executed.                                                                                                   |
| 3602H           | Counting of the high-speed I/O module counter, pulse width measurement, or PWM starts/stops by the HIOEN instruction at interrupt priorities 1 to 16 of the interrupt program. |
| 3781H           | Ring length ≤ preset value is specified and executed in channel for which ring length is set and preset input is enabled.                                                      |

## 26.1 Mechanical OPR

The positioning instruction increases and decreases the content of the current address when a forward pulse or reverse pulse is generated.

As the current address is cleared when the controller is powered off, after the power is turned on, the mechanical position and the current address in the controller must be matched. Perform homing using the DSZR/DDSZR instruction for machine OPR to match the mechanical position and the current address in the controller.

### DSZR/DDSZR

This instruction executes mechanical zero return.

- DSZR: Specifies the operand with 16-bit data.
- DDSZR: Specifies the operand with 32-bit data.

| Ladder | Structured text                                                   | FBD/LD |

\*1 Two devices are occupied from the specified device.

\*2 FX and FY cannot be used.

\*3 T, ST, C, and FD cannot be used.

\*4 J□\□ cannot be used.

## Processing details

This instruction executes mechanical zero return.

With the forward limit or reverse limit, zero return with the dog search function can be executed. For details on the dog search function, refer to the following.

 User's manual for the controller used

(1) When the driving contact is turned on, pulses are output and acceleration is performed at the bias speed.

(2) After the OPR speed is reached, the operation will be performed at the OPR speed.

(3) When the near-point dog signal is detected, deceleration is performed.

(4) After the speed has reached the creep speed, the operation will be performed at the creep speed.

(5) When a zero signal is detected after the near-point dog signal is turned on and off, the pulse output is stopped.

- For (s1), specify the OPR speed. Set a value between 1pps and 200kpps using pulse conversion.
- For (s2), specify the creep speed. Set a value between 1pps and 200kpps using pulse conversion.
- For (d1), specify the axis number from which pulses are output. Specify the axis number in which positioning parameters are set in high speed I/O parameters. The operation is not performed if an axis number with no setting is specified.
- Specify the bit device of the instruction execution complete flag for (d2), and specify the bit device of the abnormal end flag for (d2)+1.
- The near-point dog signal and zero-phase signal function follow the device set with parameters. The OPR speed and creep speed specified by the operand overwrite the OPR speed and creep speed of the special register. When the operand is indirectly specified, the special register values are also changed according to the changes in the device values of the operand.

- The pulse output direction is determined by the OPR direction and rotation direction settings. The following shows the operation of when the OPR direction and rotation direction settings are combined.

| Item          |                                                   | Rotation direction setting                             |                                                        |
|---------------|---------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------|
|               |                                                   | Current address increase by forward pulse output       | Current address increase by reverse pulse output       |
| OPR direction | Positive direction (address increasing direction) | Output direction: Forward rotation, Address: Increases | Output direction: Reverse rotation, Address: Increases |
|               | Negative direction (address decreasing direction) | Output direction: Reverse rotation, Address: Decreases | Output direction: Forward rotation, Address: Decreases |

- Changes made to the command velocity during positioning operation for the OPR speed (s1) and creep speed (s2) are effective before zero signal detection. Any command velocity changes made after zero signal detection will be reflected when the DSZR/DDSZR instruction is driven again.
- The operation timing of the completion flag is as follows. If a dwell time is specified, the operation is turned on after the dwell time has elapsed.

| Item             | Instruction execution completion flag (d2)                                                                                                                                                                       | Instruction execution abnormal end flag (d2)+1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Precautions

- The detection of the near-point dog signal (front end/back end) is influenced by the input response time and sequence program operation time. Provide at least one operation cycle between the near-point dog signal back end and the zero signal turning on.
- As the zero signal of the servo motor is used, make adjustments to establish the following relationship for the near-point dog signal back end and the zero signal. If fine adjustment is required for the home position, adjust the position of the near-point dog signal.

- Design the near-point dog signal so that it remains ON long enough to allow the speed to decelerate to the creep speed. Deceleration to achieve the creep speed starts at the front end of the near-point dog signal and stops either at the back end of the near-point dog signal or upon detection of the first zero signal from the back end of the near-point dog signal, after which the current address is cleared. If the creep speed has not been achieved by the time the back end of the near-point dog signal is reached, the stop position will vary.
- Set the near-point dog signal between reverse rotation limit 1 (LSR) and forward rotation limit 1 (LSF). When the near-point dog signal, reverse rotation limit 1 (LSR), and forward rotation limit 1 (LSF) are not in the relationship as shown in the figure below, the intended operation may not be performed.

- Set the creep speed to be sufficiently slow. Deceleration stop is not performed if the creep speed is set too high, which may cause variations in the stop position due to inertia.

## 26.2 Interrupt 1-speed Positioning

In positioning, interrupt 1-speed constant quantity feed is executed by the DVIT/DDVIT instruction.  
This instruction can control interrupt signals by a user program.

### DVIT/DDVIT

This instruction executes interrupt 1-speed constant quantity feed.

- DVIT: Specifies the operand with 16-bit data.
- DDVIT: Specifies the operand with 32-bit data.

\*1 Two devices are occupied from the specified device.

\*2 FX and FY cannot be used.

\*3 T, ST, C, and FD cannot be used.

\*4 J□\□ cannot be used.

## Processing details

This instruction executes interrupt 1-speed constant quantity feed. This instruction moves the operation from the point in which an interrupt input is detected to the specified positioning address at the commanded velocity.

- (1) When the driving contact turns on, movement will occur in the direction of the positioning address specified in (s1) at the command velocity specified in (s2).
- (2) From the point in which interrupt input signal 1 set by the parameter turns on, the pulses for the positioning address specified in (s1) are output before the operation is stopped.

- For (s1), specify the transfer distance that is output after an interrupt, in user units. Set a value between -2147483648 and 2147483647 using pulse number conversion.
- For (s2), specify the velocity in user units. Set a value between 1pps and 200kpps using pulse conversion.
- For (d1), specify the axis number from which pulses are output.
- Specify the bit device of the instruction execution complete flag for (d2), and specify the bit device of the abnormal end flag for (d2)+1.
- When interrupt input signal 1 is detected, the pulses for the positioning address specified in (s1) are output from the point in which interrupt input signal 1 is detected. The operation decelerates and stops in the point that the speed can be reduced.
- When interrupt input signal 1 is disabled, the DVIT/DDVIT instruction cannot be used. When interrupt input signal 1 cannot be detected, pulse output continues at the command velocity of (s2) until interrupt input signal 1 is detected.
- If interrupt input signal 1 was turned on before the instruction is driven, interrupt input signal 1 will not be detected even if the DVIT/DDVIT instruction is driven. However, if both an external start signal and interrupt input signal 1 are on when the external start signal is used, interrupt input signal 1 will be detected at the same time as the DVIT/DDVIT instruction is driven.

- The operation timing of the completion flag is as follows.

| Item             | Instruction execution complete flag (d2)                                                                                                                                                                         | Instruction execution abnormal end flag (d2)+1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Precautions

- The operation ends with an error if the positioning address (s1) is 0 at the start of the instruction.
- When the positioning address (s1) is changed to 0 before interrupt input signal 1 is detected, deceleration stop is performed after input interrupt. After the deceleration stop, the positioning operation starts after reversing the output direction to the address that has received the positioning address change and the operation is completed normally.
- When the travel time to move to the positioning address is shorter (the value set in (s1) is smaller) than the time required for the deceleration stop, the movement stops immediately when the positioning address is reached. Note that an immediate stop has a risk of damaging the system, as the motor is stopped without deceleration.

- When interrupt input signal 1 is detected during acceleration, the following operation is performed based on the value of the positioning address (s1).

**1.** Positioning address < Number of pulses required for deceleration from the current velocity

After interrupt input signal 1 turns on, deceleration immediately starts and an immediate stop is performed when the positioning address is reached. Note that an immediate stop has a risk of damaging the system, as the motor is stopped without deceleration.

**2.** Number of pulses required for deceleration from the current velocity  $\leq$  Positioning address < Number of pulses required for acceleration/deceleration from the current velocity

Accelerates to a position where the remaining number of pulses is equal to the number of pulses required for deceleration and then decelerates and stops.

**3.** Number of pulses required for acceleration/deceleration from the current velocity  $\leq$  Positioning address

Accelerates to the command velocity (s2) and then decelerates and stops.

# 26.3 Variable Speed Operation

During positioning, the variable speed operation is performed by the variable speed pulse output instruction. This instruction can perform operations with acceleration/deceleration when the speed is changed.

## PLSV/DPLSV

This instruction outputs variable speed pulses with an assigned rotation direction output.

- PLSV: Specifies the operand with 16-bit data.
- DPLSV: Specifies the operand with 32-bit data.

\*1 Two devices are occupied from the specified device.

\*2 FX and FY cannot be used.

\*3 T, ST, C, and FD cannot be used.

\*4 J□\□ cannot be used.

## Processing details

This instruction outputs variable speed pulses with an assigned rotation direction output.

- (1) When the driving contact is turned on, pulses are output and acceleration is performed at the bias speed.
  - (2) After the speed has reached the command velocity, the operation will be performed at the command velocity.
  - (3) If the command velocity is changed during operation, an acceleration/deceleration operation is performed and the speed is changed to the specified speed for operation.
  - (4) When the driving contact turns off, a deceleration operation is performed and the pulse output is stopped.
- For (s), specify the command velocity to be output. Set a value between 1pps and 200kpps using pulse conversion.
  - For (d1), specify the axis number from which pulses are output.
  - Specify the bit device of the instruction execution complete flag for (d2), and specify the bit device of the abnormal end flag for (d2)+1.
  - If the command velocity is changed to 0 during operation, the operation decelerates and stops without an abnormal end flag. Note that as long as the drive contact is not turned off, the pulse output will restart when the command velocity is changed.
  - If the command velocity is set to 0 when the instruction is activated, the operation is not performed.
  - When the acceleration time is 0, the speed is immediately changed to the command velocity without any acceleration operation.
  - When the deceleration time is 0, the operation immediately stops when the driving contact turns off without any deceleration operation.
  - The operation timing of the completion flag is as follows.

| Item             | Instruction execution complete flag (d2)                                                                                                                                                                         | Instruction execution abnormal end flag (d2)+1                                                                                                                                                                                                                                                                                                                                                         |

R: Read only, R/W: Read or Write, ○: Supported, ×: Not supported

## Precautions

- If a speed change is made during operation that changes the command velocity sign, an operation to start pulse output from the reverse direction is performed after a deceleration stop. The waiting time from a deceleration stop to re-output is 1ms + scan time. If the motor cannot be stopped within the waiting time, program direction switching so that the command velocity is set to 0, and output is resumed only after ensuring sufficient waiting time following a deceleration stop.
- If the command velocity (s) is 0 when the instruction is started, abnormal completion will occur without performing any operation.

# 26.4 1-speed Positioning (Relative)

This instruction executes 1-speed positioning by the incremental system (position specification by a relative address). The positioning operation is performed after specifying the movement direction and movement amount (relative address) using the current stop position as the start point.

## DRV/DDR

This instruction executes 1-speed positioning with a relative address.

- DRV: Specifies the operand with 16-bit data.
- DDR: Specifies the operand with 32-bit data.

\*1 Two devices are occupied from the specified device.

\*2 FX and FY cannot be used.

\*3 T, ST, C, and FD cannot be used.

\*4 J□□□ cannot be used.

## Processing details

This instruction executes 1-speed positioning with a relative address. Specify the positioning address in the incremental system, in which the transfer direction and transfer distance from the current position (relative address) are specified for positioning.

- (1) When the driving contact is turned on, pulses are output and acceleration is performed at the bias speed.
- (2) After the speed has reached the command velocity, the operation will be performed at the command velocity.
- (3) Deceleration operation is performed from a point near the target point.
- (4) Pulse output is stopped at the point where the specified positioning address has been moved.

- For (s1), specify the relative positioning address in user units. Set a value between -2147483647 and 2147483647 using pulse number conversion.
- For (s2), specify the command velocity in user units. Set a value between 1pps and 200kpps using pulse conversion.
- For (d1), specify the axis number from which pulses are output.
- Specify the bit device of the instruction execution complete flag for (d2), and specify the bit device of the abnormal end flag for (d2)+1.
- The operation timing of the completion flag is as follows.

| Item             | Instruction execution complete flag (d2)                                                                                                                                                                         | Instruction execution abnormal end flag (d2)+1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# 26.5 1-speed Positioning (Absolute)

This instruction executes 1-speed positioning by the absolute system (position specification by an absolute address). The positioning operation is performed after specifying the position (absolute address) using the origin as the reference. The start point can be anywhere.

## DRVA/DDRVA

This instruction executes 1-speed positioning with an absolute address.

- DRVA: Specifies the operand with 16-bit data.
- DDRVA: Specifies the operand with 32-bit data.

## Processing details

This instruction executes 1-speed positioning by absolute address drive. Specify the positioning address in the absolute system, in which the transfer distance from the origin (absolute address) is specified for positioning.

- (1) When the driving contact is turned on, pulses are output and acceleration is performed at the bias speed.
- (2) After the speed has reached the command velocity, the operation will be performed at the command velocity.
- (3) Deceleration operation is performed from a point near the target point.
- (4) Pulse output is stopped at the specified positioning address.

- For (s1), specify the absolute positioning address in user units. Set a value between -2147483647 and 2147483647 using pulse number conversion.
- For (s2), specify the command velocity in user units. Set a value between 1pps and 200kpps using pulse conversion.
- For (d1), specify the axis number from which pulses are output.
- Specify the bit device of the instruction execution complete flag for (d2), and specify the bit device of the abnormal end flag for (d2)+1.
- The operation timing of the completion flag is as follows.

| Item             | Instruction execution complete flag (d2)                                                                                                                                                                         | Instruction execution abnormal end flag (d2)+1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ON condition     | From the time when the pulse output of the specified positioning address is completed until the ON→OFF conditions are met                                                                                        | From during one of the operations below or the completion of function operation until the ON→OFF condition is met <ul style="list-style-type: none"> <li>• The axis is already used</li> <li>• Drive contact turns off during positioning operation</li> <li>• Pulse output stop command</li> <li>• Pulse deceleration stop command*1</li> <li>• Drive direction limit</li> <li>• All outputs disabled (SM9904)</li> <li>• Online change</li> <li>• Positioning address error</li> <li>• Deceleration stop when the command velocity is changed to 0</li> </ul> |
| ON→OFF condition | The ON status is held until either one of the following is executed. <ul style="list-style-type: none"> <li>• The user changes to status to OFF.</li> <li>• The positioning instruction is restarted.</li> </ul> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

\*1 The abnormal end flag does not turn on when remaining distance operation enabled is turned on.

## 26.6 Table Operation (Multiple Tables)

This instruction executes control method operation set in multiple data tables with the engineering tool.

### DRVTL

This instruction executes continuous operation or stepping operation for multiple tables with one instruction based on the table data set with the engineering tool.

| Ladder | Structured text                           | FBD/LD |

\*4 J□□□ cannot be used.

## Processing details

This instruction can execute continuous operation or stepping operation for multiple tables with one instruction based on the table data set with the engineering tool. For details including the table setting method, refer to the following.

 User's manual for the controller used

- For (d1), specify the axis number from which pulses are output.
- For (n1), specify the start table to be executed according to the output specified in (d1).
- For (n2), specify the last table.
- For (n3), specify the table execution method. Stepping operation is performed when K0 is set, and continuous operation is performed when K1 is set.
- Specify the bit device of the instruction execution complete flag for (d2), and specify the bit device of the abnormal end flag for (d2)+1.
- When (n1) and (n2) are the same, only one table is executed.
- When (n1) is larger than (n2), operation is completed normally after the last table (table 100) is executed.
- When (n3) is set to K0 (stepping operation), operation shifts to the next table if the table shift command is detected when one table is finished. Table shift processing can also be performed using an external start signal.
- The operation timing of the completion flag depends on the table control method.

\*2 J□\□ cannot be used.

## Processing details

This instruction generates the input interrupt 1 signal. For (s), specify the axis number by which to output the input interrupt 1 signal.

- Due to its characteristics, this instruction is used in combination with another instruction. The following is an example where this instruction is used in combination with the DVIT instruction.

## Precautions

- To improve the accuracy from command input to trigger start, use this instruction within an interrupt program.
- Since the DITRG instruction operates at the rising edge, when using it within an interrupt program, program it such that the driving contact OFF status can be detected.

### ■Relation to the input interrupt 1 signal

The DITRG instruction and the input interrupt 1 signal operate using the instruction received first as the trigger. Their relationship of operations is shown below.

| Instruction using the input interrupt 1 signal | Trigger                  |                   | Operation                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------|--------------------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### ■Differences from interrupt input signal 1

The following table lists the differences in specifications between interrupt input signal 1 and the DITRG instruction.

| Items with differences              | Interrupt input signal 1                                                        | DITRG instruction                                                       |
|-------------------------------------|---------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Parameter: Interrupt input signal 1 | [0: Disable]→The interrupt does not occur.<br>[1: Enable]→The interrupt occurs. | [0: Disable]→The interrupt occurs.<br>[1: Enable]→The interrupt occurs. |
| Operand overwrite                   | Supported                                                                       | Not supported                                                           |

## 26.8 Restoring the Absolute Position

This instruction reads the absolute position (ABS) data of the servo amplifier by connecting to the servo amplifier supporting the absolute position restoration function.

The data is converted into pulse when being read.

\*1 Two devices are occupied from the specified device.

\*2 FX and FY cannot be used.

\*3 T, ST, C, and FD cannot be used.

\*4 J□\□ cannot be used.

## Processing details

This instruction reads the absolute position (ABS) data by connecting to the servo amplifier. The data is converted into pulse when being read.

- For (s), specify the head device number that inputs the output signal for ABS data from the servo amplifier. Three devices are occupied from (s). Specify ABS(bit0) for (s), ABS(bit1) for (s)+1, and the send data ready signal for (s)+2.
- For (d1), specify the head device number that outputs the ABS data control signal to the servo amplifier. Three devices are occupied from (d1). Specify servo ON for (d1), ABS transfer mode for (d1)+1, and the ABS request signal for (d1)+2.
- For (d2), specify the device that stores the ABS data read from the servo amplifier. Set a value between -2147483647 and 2147483647 using pulse number conversion.
- Specify the bit device of the instruction execution complete flag for (d3), and specify the bit device of the abnormal end flag for (d3)+1.

### ■Absolute position detection operation

1. When the DABRST instruction is driven, the programmable controller drives servo ON output and ABS transfer mode output.
2. While the transmitted data ready signal and the ABS request signal check the send/receive status of each other, 32+6 bit data is communicated.
3. Data is transmitted using two bit lines: ABS bit0 and bit1.
4. When ABS data reading is completed, the execution completed flag operates.

### ■First home seek

Even when a servo motor with the absolute position detection function is used, home seek must be performed at least once when creating a system to send a clear signal to the servo motor.

Perform the first home seek by one of the following procedures.

- Use the DSZR/DDSZR instruction to enable the clear signal function and execute homing.
- Seek the home position of the system by JOG operation or manual position adjustment and input a clear signal to the servo amplifier. To input a clear signal, use the output of the programmable controller or use an external switch as shown in the figure below.

## Precautions

For details on the servo amplifier, refer to the manual for each servo amplifier used.

- Design the system so that the power to the controller and servo amplifier is turned on simultaneously or the servo amplifier is turned on first.
- Keep the driving contact turned on even after the ABS value is read. If the instruction driving contact is turned off after ABS value reading is completed, operation is not performed as the servo ON (SON) signal turns off.
- If the driving contact is turned off during reading, reading is interrupted.
- Even when data cannot be communicated with the servo amplifier, it cannot be detected as an error. Therefore, the status needs to be monitored by the timeout determination timer.
- When using the DABRST instruction, set the rotation direction of the servo motor according to the relationship shown below. Note that, when other settings are configured, the current value controlled by the programmable controller and the sign (positive/negative) in the servo amplifier may not match after the ABS value is read.

| Rotation direction                                     | Servo amplifier settings                                                                                                      |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Current value increasing with a forward rotation pulse | Forward rotation (CCW) when a forward rotation pulse is input<br>Reverse rotation (CW) when a reverse rotation pulse is input |
| Current value decreasing with a reverse rotation pulse | Reverse rotation (CW) when a forward rotation pulse is input<br>Forward rotation (CCW) when a reverse rotation pulse is input |

## Operation error

| Error code | Description                                                                                     |
|------------|-------------------------------------------------------------------------------------------------|
| 1811H      | 17 or more ABRST instructions were executed at the same time.                                   |
| 1820H      | An online change was performed for a program file in which the ABRST instruction was operating. |

## Processing details

These instructions transfer the data in the device specified by (s) to the device specified by (d). At this time, if the value of (n) is K0, the value of (s) is not cleared. If the value of (n) is K1, the value of (s) is cleared to "0" after the transfer.

### Point

When (s) is a device supporting high-speed transfer

- When the HCMOV instruction is executed, the latest value is acquired such as the current value of a high-speed counter and transferred to (d).

When (d) is a device supporting high-speed transfer

- When the HCMOV instruction is executed, values such as the current value of a high-speed counter can be changed.

### ■Effect of HCMOV instruction

- By using both input interrupt and HCMOV instruction, the current value of a high-speed counter can be received at the rising edge or falling edge of an external input.
- When HCMOV instruction is used just before a comparison instruction (CMP, ZCP or comparison contact instruction), the latest value of the high-speed counter is used in comparison. The HCMOV instruction can be used repeatedly as there is no limitation to the number of uses.

## Precautions

- When it is necessary to execute comparison and outputting as soon as the current value of a high-speed counter changes, use the high-speed comparison table.
- If 32-bit binary data special device which supports the high-speed transfer (such as the current value of a high-speed counter) is read using the HCMOV instruction, the operation is the same as that when the MOV instruction is used. Updating to the latest value or overwriting the internal register is not possible.
- Do not overwrite the current value of a high-speed counter using the HCMOV instruction while executing the pulse density (rotation speed measurement) or the SPD instruction.
- Transfer is not possible between an SM/SD supporting HCMOV.

### Point

The HCMOV instruction is mainly used to read the current value of the high-speed counter/pulse width measurement and change the current address (in the user units) or the current address (in the pulse unit) of positioning.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                       |

## Processing details

These instructions transfer the data in the device specified by (s) to the device specified by (d). At this time, if the value of (n) is K0, the value of (s) is not cleared. If the value of (n) is K1, the value of (s) is cleared to "0" after the transfer.

### Point

When (s) is a device supporting high-speed transfer

- When the DHCMOV instruction is executed, the latest value is acquired such as the current value of a high-speed counter and transferred to (d).

When (d) is a device supporting high-speed transfer

- When the DHCMOV instruction is executed, values such as the current value of a high-speed counter can be changed.

## Effect of DHCMOV instruction

- By using both input interrupt and DHCMOV instruction, the current value of a high-speed counter can be received at the rising edge or falling edge of an external input.
- When DHCMOV instruction is used just before a comparison instruction (DCMP, DZCP or comparison contact instruction), the latest value of the high-speed counter is used in comparison. The DHCMOV instruction can be used repeatedly as there is no limitation to the number of uses.

## Precautions

- When it is necessary to execute comparison and outputting as soon as the current value of a high-speed counter changes, use the high-speed comparison table.
- Do not overwrite the current value of a high-speed counter using the DHCMOV instruction while executing the pulse density (rotation speed measurement) or the DSPD instruction.
- Do not specify an operand that crosses the boundary of BIN32 bit SD using the DHCMOV instruction. Otherwise, the setting value may become corrupted.
- Transfer is not possible between an SM supporting high-speed transfer and an SD supporting high-speed transfer.
- When setting a value larger than the ring length for the preset value of the high-speed counter SD, if a value is set while the high-speed counter has stopped, an error occurs. However, if a value is set while the high-speed counter is operating, the setting value is reflected without any error.
- When a high-speed counter SD device (current value, maximum value, minimum value) is read out individually, only the read SD device will be updated. Thus, there may be cases when the high-speed counter SD device does not satisfy the relation of minimum value  $\leq$  current value  $\leq$  maximum value temporarily.

### Point

The DHCMOV instruction is mainly used to read the current value of the high-speed counter/pulse width measurement and change the current address (in the user units) or the current address (in the pulse unit) of positioning.

## Operation error

# 28 PULSE RELATED INSTRUCTIONS

## 28.1 16 Bit Binary/32 Bit Binary Pulse Width Modulation

### 16 bit binary pulse width modulation

#### PWMH

This instruction outputs the pulse (in 16-bit data units) of the ON time (in 16-bit data units) specified by (s1) and the period specified by (s2) to the output destination specified by (d).

## Processing details

- This instruction outputs the pulse of the ON time specified by (s1) and the period specified by (s2) to the output destination specified by (d).

- Time with a unit selected in the parameter setting window ( $\mu\text{s}$  or  $\text{ms}$ ) can be specified by (s1) and (s2).
- The pulse output destination channel number selected in the parameter setting window can be specified by (d).
- This instruction store the number of pulses, pulse width, and period output from each channel to an SD device. The pulse width and period are stored in the units set by the parameters. When 0 is specified in the pulse output, pulses are output without any limitation.

| Pulse output destination channel | Number of output pulses | R/W | Initial value | Timing of reflection on operation                                                                                                                                   | Timing of clearing to initial value |

\*1 When the DHCMOV instruction is used, the latest value can be read. A writable device can be updated immediately.

\*2 Parameter setting values are set to an SD device at STOP to RUN.

\*3 When this instruction is executed, the pulse width and period specified (s1) and (s2) are set to an SD device.

• After the pulse output is started from each channel, the pulse output monitor turns on.

| Pulse output destination channel | Pulse output monitor | R/W | Initial value | ON timing                                                                                                                               | OFF timing                                                                                                                                                                                          |

- The number of output pulses set to an SD device is valid for this instruction as well. The setting values are always read and updated.
- When the specified number of output pulses is equal to or less than the number of pulses which have already been output, pulse output stops after outputting pulses which are being output.
- When the specified number of output pulses is larger than the number of pulses which have already been output, pulse output stops after outputting set number of pulses.
- When the number of output pulses is set from the no limitation output setting (number of output pulses is 0), the number of output pulses is not updated (because outputting pulses continues or stops in the no limitation output).
- The maximum number of output pulses which can be output when the PWMH instruction is executed once (= maximum value which can be set to an SD device) is "2147483647".
- The ON time and period can be set during the pulse output. Setting values are always read and updated.
- When the number of output pulses is 0 (no limitation output setting), the monitor of the current number of output pulses is set to 0.
- When the number of output pulses is specified, the output pulses are monitored. When the PWMH output is executed several times, the monitor of the number of output pulses is an integrated value.
- The monitor of the current number of output pulses can be changed during the pulse output.
- The monitor of the current number of output pulses is updated when the number of pulses is counted at the falling edge of pulses in the positive logic and at the rising edge of pulses in the negative logic.
- When the output always remains ON or OFF, the monitor of the current number of output pulses does not change.
- The maximum value of the monitor of the current number of output pulses is "FFFFFFFFH". After the current number of output pulses reaches the maximum value, the monitor of the current number of output pulses starts to count again from "0".

## Precautions

- Specify the ON time by (s1) and the period by (s2) so that (s1) is equal to or larger than  $2\mu\text{s}$  and (s2) is equal to or larger than  $5\mu\text{s}$ .
- When a channel number that is not selected for the PWM output in the parameter setting is specified for (d), this instruction is not executed. An operation error occurs.
- Operations when the PWM output is stopped (while the output pulse is on)

- Operations when the PWM output is stopped (while the output pulse is off)

- The PWM output stops when SM9904 is on, and starts when it is off.
- PWM output does not stop, even if a pulse stop command for positioning is driven.
- When specifying the number of output pulses, executing the PWMH instruction, and then outputting pulses again after the pulse output stops due to the completion of output of the specified number of pulses, turn OFF the contact which drove the PWMH instruction. When driving PWM output by the HIOEN instruction, use the HIOEN instruction to turn PWM output off.
- When the period setting is equivalent to the ON time setting, the output always remains ON. The output ON state continues even after "Period  $\times$  Number of output pulses" is finished in this condition.
- Pulse output does not start even when the PWMH instruction is added during an online change. When the drive contact is on, pulse output can be started by turning the drive contact off and on.
- When the PWMH instruction is changed or deleted after online change occurs, pulse output is stopped.
- If an online change occurs while the PWMH instruction is present during pulse output, pulse output is stopped and the control right is released for the stopped channel.

## Operation error

| Error code (SD0)                                     | Description                                                                                                               |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|

| 3600H                                                | A channel number that is not selected in the parameter setting are specified for the output destination specified by (d). |
| 3611H(CH1)<br>3612H(CH2)<br>3613H(CH3)<br>3614H(CH4) | This instruction is executed with a setting in which (s2) is smaller than (s1).                                           |

## 32 bit binary pulse width modulation

### DPWMH

This instruction outputs the pulse (in 32-bit data units) of the ON time (in 32-bit data units) specified by (s1) and the period specified by (s2) to the output destination specified by (d).

## Processing details

- This instruction outputs the pulse of the ON time specified by (s1) and the period specified by (s2) to the output destination specified by (d).

- Time with a unit selected in the parameter setting window ( $\mu\text{s}$  or  $\text{ms}$ ) can be specified by (s1) and (s2).
- The pulse output destination channel number selected in the parameter setting window can be specified by (d).
- This instruction store the number of pulses, pulse width, and period output from each channel to an SD device. The pulse width and period are stored in the units set by the parameters. When 0 is specified in the pulse output, pulses are output without any limitation.

| Pulse output destination channel | Number of output pulses | R/W | Initial value | Timing of reflection on operation                                                                                                                                     | Timing of clearing to initial value |

\*1 When the DHCMOV instruction is used, the latest value can be read. A writable device can be updated immediately.

\*2 Parameter setting values are set to an SD device at STOP to RUN.

\*3 When this instruction is executed, the pulse width and period specified (s1) and (s2) are set to an SD device.

• After the pulse output is started from each channel, the pulse output monitor turns on.

| Pulse output destination channel | Pulse output monitor | R/W | Initial value | ON timing                                                                                                                                 | OFF timing                                                                                                                                                                                          |

| CH4                              | SD5355, SD5354                                 |     |               |                                                                                                                                                      |                                                                                                     |

- The number of output pulses set to an SD device is valid for this instruction as well. The setting values are always read and updated.
- When the specified number of output pulses is equal to or less than the number of pulses which have already been output, pulse output stops after outputting pulses which are being output.
- When the specified number of output pulses is larger than the number of pulses which have already been output, pulse output stops after outputting set number of pulses.
- When the number of output pulses is set from the no limitation output setting (number of output pulses is 0), the number of output pulses is not updated (because outputting pulses continues or stops in the no limitation output).
- The maximum number of output pulses which can be output when the DPWMH instruction is executed once (= maximum value which can be set to an SD device) is "2147483647".
- The ON time and period can be set during the pulse output. Setting values are always read and updated.
- When the number of output pulses is 0 (no limitation output setting), the monitor of the current number of output pulses is set to 0.
- When the number of output pulses is specified, the output pulses are monitored. When the DPWMH output is executed several times, the monitor of the number of output pulses is an integrated value.
- The monitor of the current number of output pulses can be changed during the pulse output.
- The monitor of the current number of output pulses is updated when the number of pulses is counted at the falling edge of pulses in the positive logic and at the rising edge of pulses in the negative logic.
- When the output always remains ON or OFF, the monitor of the current number of output pulses does not change.
- The maximum value of the monitor of the current number of output pulses is "FFFFFFFFH". After the current number of output pulses reaches the maximum value, the monitor of the current number of output pulses starts to count again from "0".

## Precautions

- Specify the ON time by (s1) and the period by (s2) so that (s1) is equal to or larger than  $2\mu\text{s}$  and (s2) is equal to or larger than  $5\mu\text{s}$ .
- When a negative value is specified for the ON time by (s1) and the period by (s2), an operation error occurs.
- When a channel number that has not been selected for the PWMH output in the parameter setting is specified for (d), this instruction is not executed. An operation error occurs.
- Operations when the DPWM output is stopped (while the output pulse is on)

- Operations when the DPWMH output is stopped (while the output pulse is off)

- The PWM output stops when SM9904 is on, and starts when it is off.
- PWM output does not stop, even if a pulse stop command for positioning is driven.
- When specifying the number of output pulses, executing the DPWMH instruction, and then outputting pulses again after the pulse output stops due to the completion of output of the specified number of pulses, turn OFF the contact which drove the DPWMH instruction. When driving PWM output by the DHIOEN instruction, use the DHIOEN instruction to turn PWM output off.
- When the period setting is equivalent to the ON time setting, the output always remains ON. The output ON state continues even after "Period  $\times$  Number of output pulses" is finished in this condition.

## Processing details

This instruction counts the device input specified by (s1) only for the time specified by (s2) and stores the operation result in the device specified by (d).

## Precautions

- The maximum frequency of turning the X00 to X0F inputs on and off is 200kHz for X00 to X05 and 10kHz for X06 and X07.
- When the measurement time of the operand is changed while the SPDH instruction is executed, the changed time is applied every time the measurement time ends.
- When the current value of the high-speed counter is overwritten by the HCMOV instruction or the current value is changed by an external preset input or reset by itself while the SPDH instruction is executed, the pulse density cannot be measured normally. (The operation continues.)
- When the SPDH instruction is used, do not input the number of pulses that exceeds the ring length of the high-speed counter/2 within the measurement time. If such value is input, the number of pulses cannot be calculated correctly.

Ring counter length/2

- The measurement time specified by the operand of the SPDH instruction overwrites the SD of the measurement unit time used for the pulse density (rotation speed) measurement function.
- When the measurement time is outside the range from 1 to 2147483647, the specified measurement time is rounded into "1" with the sign.
- For the SPDH instruction, only the channel number in which the high-speed counter parameters are set can be specified. Specify the channel number or the X number of phase A for (s1). If a channel to which no parameters are set is specified, the operation error H3600 occurs.
- When the SPDH instruction is executed, the UP/DOWN pulse input, preset input, and enable input operate in accordance with the parameter settings of the high-speed counter.
- When the SPDH instruction starts or stops, the common high-speed counter function starts or stops simultaneously with the pulse density measurement function.
- In a state where the high-speed counter has been driven by the HIOEN instruction (K0: High-speed counter), the pulse density measurement does not start and no error occurs even when driving is performed while specifying a running channel for the SPDH instruction.

## Operation error

# Measuring the density of 32 bit data pulses

28

## DSPDH

Measures the input pulse for the specified time with interrupt input.

| Ladder diagram                                                                    | Structured text                    |

## Processing details

This instruction counts the device input specified by (s1) only for the time specified by (s2)+1 or (s2) and stores the operation result in the device specified by (d)+1 or (d).

## Precautions

- The maximum frequency of turning the X00 to X0F inputs on and off is 200kHz for X00 to X05 and 10kHz for X06 and X07.
- When the measurement time of the operand is changed while the SPDH instruction is executed, the changed time is applied every time the measurement time ends.
- When the current value of the high-speed counter is overwritten by the HCMOV instruction or the current value is changed by an external preset input or reset by itself while the SPDH instruction is executed, the pulse density cannot be measured normally. (The operation continues.)
- When the SPDH instruction is used, do not input the number of pulses that exceeds the ring length of the high-speed counter/2 within the measurement time. If such value is input, the number of pulses cannot be calculated correctly.

Ring counter length/2

- The measurement time specified by the operand of the SPDH instruction overwrites the SD of the measurement unit time used for the pulse density (rotation speed) measurement function.
- When the measurement time is outside the range from 1 to 2147483647, the specified measurement time is rounded into "1" with the sign.
- For the SPDH instruction, only the channel number in which the high-speed counter parameters are set can be specified. Specify the channel number or the X number of phase A for (s1). If a channel to which no parameters are set is specified, the operation error H3600 occurs.
- When the SPDH instruction is executed, the UP/DOWN pulse input, preset input, and enable input operate in accordance with the parameter settings of the high-speed counter.
- When the SPDH instruction starts or stops, the common high-speed counter function starts or stops simultaneously with the pulse density measurement function.
- In a state where the high-speed counter has been driven by the HIOEN instruction (K0: High-speed counter), the pulse density measurement does not start and no error occurs even when driving is performed while specifying a running channel for the SPDH instruction.

## Operation error

| 3600H            | A channel number or word device that is not selected in the parameter setting is specified in (s1).             |

# PART 5

# NETWORK INSTRUCTIONS

This part consists of the following chapters.

For the dedicated instructions in using the intelligent function module with the MX-F model, refer to the following.

 MELSEC iQ-F FX5 Programming Manual (Instructions, Standard Functions/Function Blocks)

29 Ethernet INSTRUCTIONS

---

30 EXTERNAL DEVICE COMMUNICATION INSTRUCTIONS

---

# 29 Ethernet INSTRUCTIONS

For the dedicated instructions in using the intelligent function module with the MX-F model, refer to the following.  
MELSEC iQ-F FX5 Programming Manual (Instructions, Standard Functions/Function Blocks)

## 29.1 Open/Close Processing Instructions

Point

For connections where any of the following instructions is being executed, a request is ignored even if the following multiple instructions are attempted to be executed.

At this time, as long as the execution conditions of the instruction executed later are met, the request is executed after the first instruction being executed completes. SM699 (Dedicated instruction skip flag) turns on while the request is ignored.

- SOCOPEN instruction
- SOCCLOSE instruction
- SOCSND instruction
- SOCRCV instruction
- ECPRTCL instruction

### Opening a connection

#### GP.SOCOPEN, SP.SOCOPEN

This instruction opens the specified connection.

\*1 In Unpassive open mode, the IP address of the external device and destination port number are ignored.

\*2 If 65535 (FFFFH) is specified for the port number, data cannot be sent. To send data, specify a value within the range of 1 to 65534 (1 to FFFE H).

\*3 The setting items that are not included in the control data are as follows.

Alive check: KeepAlive (for TCP/TLS), UDP (for UDP/DTLS)

Connection monitoring timer setting: Invalid

### Point

Since port numbers 0001H to 03FFH are generally reserved port numbers (WELL KNOWN PORT NUMBERS) and F000H to FFFE H are used dynamically by the other functions, use of port numbers 0400H to 1387H and 1392H to EFFFH is recommended.

## Processing details

- This instruction opens the connection specified by (s1). The setting value used for open processing is selected by (s2)+0.
- The execution status and the completion status of this instruction can be checked with the completion device (d) specified by the setup data and the completion status indication device (d)+1.

- Completion device (d)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- The following figure shows the execution timing of this instruction.

- A connection which has not been set by a parameter (a connection whose protocol field is left blank) can be opened and used. To do so, set (s2)+0 to 8000H and specify the details of open in (s2)+1 to (s2)+9 of control data.

### Point

This instruction supports the encrypted predefined protocols (TLS and DTLS). For more details, check the user's manual for the controller used.

## Precautions

- The following table describes precautions to be taken when establishing a connection on an Ethernet port. For details on how to check the connection status, check the user's manual for the controller used.

| Item                                                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A connection is established with TCP/IP or TLS protocol, and in FullPassive mode                                                      | <p>After executing this instruction, if a connection request is received from an external device with an IP address that is not set in the external device connection configuration, a normal response is returned, but then the connection is disconnected. From the perspective of the external device, the connection is established once and then disconnected.</p> <p>For how to check whether the connection establishment is successful, check the completion status of the following instructions. If the connection establishment is successful, 0000H is stored. If the connection establishment fails, C1B1H is stored.</p> <ul style="list-style-type: none"> <li>• SOCSND instruction</li> <li>• SOCRCV instruction</li> <li>• SOCCSET instruction</li> <li>• ECPRTCL instruction</li> </ul>                                                                                         |
| A connection is established again after establishing a connection with TCP/IP or TLS protocol, and in FullPassive mode/UnPassive mode | <p>While a connection has been established by a connection request from the external device after executing this instruction, if another connection request is received from the external device, the request will not be accepted and the connection will be disconnected. (For example, the external device may be reset before executing the SOCCLOSE instruction after establishing the connection, and the external device may request to open the connection again.)</p> <p>The controller requires several hundred milliseconds to be able to accept the connection request again, so the external device should wait 1 to 2 seconds after checking the disconnection before sending another connection request.</p> <p>Also, to determine whether the reconnection request on the external device was successful, check whether the connection status on the external device is open.</p> |

- Do not execute the Ethernet function add-on and the Ethernet instruction at the same time. If they are executed at the same time, malfunction may occur.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |

Upon completion with an error, the completion status indication device (d)+1 is turned on and an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

 User's manual for the controller used

# Closing a connection

## GP.SOCCLOSE, SP.SOCCLOSE

This instruction closes the specified connection.

| Ladder | ST                                                                         |

## Processing details

- This instruction performs close processing for the connection specified by (s1).
- The execution status and the completion status of this instruction can be checked with the completion device (d) specified by the setup data and the completion status indication device (d)+1.

- Completion device (d)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- The following figure shows the execution timing of this instruction.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |

Upon completion with an error, the completion status indication device (d)+1 is turned on and an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

📖 User's manual for the controller used

### Point

When a connection waiting for opening the SOCCLOSE instruction is specified in TCP/TLS/DTLS Passive mode, a successful completion occurs when the SOCOPEN or SOCCLOSE instruction is issued and the connection is closed.

# 29.2 Socket Communications Instructions

For connections where any of the following instructions is being executed, a request is ignored even if the following multiple instructions are attempted to be executed.

At this time, as long as the execution conditions of the instruction executed later are met, the request is executed after the first instruction being executed completes. SM699 (Dedicated instruction skip flag) turns on while the request is ignored.

- SOCOPEN instruction
- SOCCLOSE instruction
- SOCSND instruction
- SOCRCV instruction
- ECPRTCL instruction

## Reading receive data during the END processing

### GP.SOCRCV, SP.SOCRCV

This instruction reads the receive data of the specified connection, during END processing after instruction execution, from the socket communications receive data area.

| Ladder | ST                                                                     |

| +0            | Receive data length | The length of the data read from the socket communications receive data area is stored.<br>(Number of bytes)             | 0 to 10238    | System |
| +1 to +□      | Receive data        | The data read from the socket communications receive data area is stored sequentially in ascending order of addresses.*1 | —             | System |

\*1 The received data is stored in units of bytes sequentially from lower bytes. When an odd number of bytes of data is received, the last receive data is stored in the lower byte of the last data storage area.

### Point

- When this instruction is executed, receive data is read from the socket communications receive data area during END processing. For this reason, executing this instruction prolongs the scan time.
- When an odd number of bytes of data is received, invalid data is stored in the upper byte of the device where the last receive data is stored.

## Processing details

- This instruction reads the receive data of the connection specified by (s1) from the socket communications receive data area (where the data received from an external device in each connection is stored) by the END processing after the instruction execution.

- The execution status and the completion status of this instruction can be checked with the completion device (d2) specified by the setup data and the completion status indication device (d2)+1.

- Completion device (d2)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d2)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- The following figure shows the execution timing of this instruction.

### Point

This instruction supports the encrypted predefined protocols (TLS and DTLS). For more details, check the user's manual for the controller used.

## Precautions

When reading receive data from the same connection, do not use this command together with the SOCRCVS instruction.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |

Upon completion with an error, the completion status indication device (d2)+1 is turned on and an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

📖 User's manual for the controller used

- 
- To avoid receiving too much amount of data, the SOCRMODE instruction can be used to set the size of receive data to limit the amount of receive data.
  - By connecting the completion device of this instruction to the execution instruction through a normally closed contact, data can be read continuously even when it is received continuously.
-

# Reading receive data when the instruction is executed

29

## G.SOCRCVS, S.SOCRCVS

This instruction reads the receive data of the specified connection from the socket communications receive data area.

| Ladder | ST                                                             |

## Control data

| Operand: (d) |                     |                                                                                                                          |               |        |
|--------------|---------------------|--------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| Device       | Item                | Description                                                                                                              | Setting range | Set by |
| +0           | Receive data length | The length of the data read from the socket communications receive data area is stored.<br>(Number of bytes)             | 0 to 10238    | System |
| +1 to +□     | Receive data        | The data read from the socket communications receive data area is stored sequentially in ascending order of addresses.*1 | —             | System |

\*1 The received data is stored in units of bytes sequentially from lower bytes. When an odd number of bytes of data is received, the last receive data is stored in the lower byte of the last data storage area.

### Point

- The default receive data size is 2046 bytes. To receive 2047 bytes of data or more, change the receive data size using the SOCRMODE instruction.
- When an odd number of bytes of data is received, invalid data is stored in the upper byte of the device where the last receive data is stored.

## Processing details

- The S.SOCRCVS instruction reads the receive data of the connection specified by (s) from the socket communications receive data area (where the data received from an external device in each connection is stored).

- The following figure shows the timing of receive processing using this instruction.

### Point

This instruction supports the encrypted predefined protocols (TLS and DTLS). For more details, check the user's manual for the controller used.

## Precautions

When reading receive data from the same connection, do not use this command together with the SOCRCV instruction.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s) is outside the range.                            |

### Point

To avoid receiving too much amount of data, the SOCRMODE instruction can be used to set the size of receive data to limit the amount of receive data.

# Sending data

## GP.SOCSND, SP.SOCSND

This instruction sends the data to the external device of the specified connection.

| Ladder                                                                            | ST                                                                           |

| +0            | System area       | —                                                                                                                                                                  | —             | —      |
| +1            | Completion status | The completion status is stored upon completion of the instruction.<br>• 0000H: Completed successfully<br>• Other than 0000H: Completed with an error (error code) | —             | System |

| Operand: (s3) |                  |                                                 |               |        |
|---------------|------------------|-------------------------------------------------|---------------|--------|
| Device        | Item             | Description                                     | Setting range | Set by |
| +0            | Send data length | Specify the send data length. (Number of bytes) | 1 to 10238    | User   |
| +1 to +□      | Send data        | Specify the send data.* <sup>1</sup>            | —             | User   |

\*1 The send data is sent in units of bytes sequentially from lower bytes. When an odd number of bytes of data is sent, store the last send data in the lower byte of the last data storage area.

#### Point

When TCP is used, the send data length should be equal to or less than the maximum window size (receive buffer) of the external device.

When TLS is used, the length of send data before encrypted should be equal to or less than the maximum window size (receive buffer) of the external device.

Data which exceeds the maximum window size of the external device cannot be sent.

## Processing details

- Sends the data in the device specified by (s3) to the external device of the connection specified by (s1).

- The execution status and the completion status of this instruction can be checked with the completion device (d) specified by the setup data and the completion status indication device (d)+1.

- Completion device (d)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- The following figure shows the timing of send processing using this instruction.

Even after the completion device turns on, data may be sent continuously. Check the completion of the send processing on the receiving side.

## Precautions

Create a means of arrival check on both the own station and the external device to check that the send data arrives at the external device and data transmission is completed successfully after the instruction is executed.

If a connection is established with the external device by using TCP/IP or TLS protocol, and then this instruction is executed to send data to the external device, the execution of this instruction is completed without checking the arrival of that data at the external device, and the completion status ((S2)+1) becomes completed successfully.

For example, create a program that notifies the external device when data was successfully sent, to notify the external device of arrival.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |
| 3293H            | The length of send data specified by (s3) is outside the range.                         |

Upon completion with an error, the completion status indication device (d)+1 is turned on and an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

 User's manual for the controller used

# Reading connection information

## GP.SOCCINF, SP.SOCCINF

This instruction reads the connection information of the connection specified by (s1) and stores it in the device specified by (d) and later.

## Processing details

Reads the connection information of the connection specified by (s1).

### Point

This instruction supports the encrypted predefined protocols (TLS and DTLS). For more details, check the user's manual for the controller used.

In TCP/TLS/DTLS Passive mode, if this instruction is executed when connection is open and a connection with the external device is not established, data other than information of the external device is stored as follows. In addition, when connection is not open, 0H is stored.

| Device     | Item                          | Data to be stored                                                             |                        |
|------------|-------------------------------|-------------------------------------------------------------------------------|------------------------|

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |

When completed with an error, an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

 User's manual for the controller used

# Changing the communication target (UDP/IP)

29

## GP.SOCCSET, SP.SOCCSET

This instruction changes the communication target IP address and port number of the specified connection.

| Ladder | ST                                                                   |

| +4            | Destination port number       | Store the destination port number of an external device.                                                                                                                                                             | 0001H to FFFFH<br>(FFFFH: simultaneous broadcast)            | User   |

## Processing details

In UDP communications, this instruction changes the communication target IP address and port number of the connection specified by (s1).

### Point

- Using this instruction allows the user to change the communication destination without closing the connection.
- If this instruction is executed while there is data in the receive data area, the instruction is validated after the SOCRCV instruction or SOCRCVS instruction is executed. If this instruction is executed while there is no data in the receive data area, the instruction is validated soon after it is executed.

## Precautions

Do not use this instruction to change the communication destination during execution of the SOCSND instruction.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |

When completed with an error, an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

📖 User's manual for the controller used

# Changing the receive mode

## GP.SOCRMODE, SP.SOCRMODE

This instruction changes the TCP/TLS receive mode and receive data size for the specified connection (invalid for UDP/DTLS communications connections).

\*1 This item is invalid for UDP/DTLS communications connections.

## Processing details

- This instruction changes the TCP/TLS receive mode and receive data size for the connection (other than a UDP/DTLS communications connection) specified by (s1).
- For TCP/TLS connections, the function enables the mode specified by (s2)+2.

### Point

This instruction supports the encrypted predefined protocol (TLS). For more details, check the user's manual for the controller used.

### ■TCP/TLS standard receive mode

Upon receipt of data, the instruction stores the data in the socket communications receive data area and turns on SD1506, and SD2132 to SD2135 (socket communications receive status signal).

If the received data exceeds the specified receive data size, the excess data becomes the next receive data.

If data is received later before data is read from the socket communications receive data area using the SOCRCV instruction or SOCRCVS instruction, it is stored in the receive data area in the OS.

If the receive data area in the OS contains data when data is read from the socket communications receive data area using the SOCRCV instruction or SOCRCVS instruction, the instruction stores the data in the socket communications receive data area and turns on SD1506 and SD2132 to SD2135 (socket communications receive status signal).

### Ex.

When 500 bytes of data is received while the receive data size is set to 300 bytes

## ■TCP/TLS fixed-length receive mode

Upon receipt of data, the instruction stores the data in the socket communications receive data area. If the specified receive data size is not reached, SD1506 and SD2132 to SD2135 (socket communications receive status signal) does not turn on. Data reception is repeated until the received data reaches the receive data size. When it reaches the receive data size, SD1506 and SD2132 to SD2135 (socket communications receive status signal) turn on.

If the received data exceeds the specified receive data size, the excess data becomes the next receive data.

If data is received later before data is read from the socket communications receive data area using the SOCRCV instruction or SOCRCVS instruction, it is stored in the receive data area in the OS.

If the receive data area in the OS contains data when data is read from the socket communications receive data area using the SOCRCV instruction or SOCRCVS instruction, the instruction stores the data in the socket communications receive data area, but does not turn on SD1506 and SD2132 to SD2135 (socket communications receive status signal) if the data has not reached the specified receive data size.

Then data reception is repeated until the received data reaches the receive data size. When it reaches the receive data size, SD1506 and SD2132 to SD2135 (socket communications receive status signal) turn on.

### Ex.

When 200 bytes of data is received continuously while the receive data size is set to 300 bytes

### Point

- Effective use of devices

The receive data storage device used by the SOCRCV instruction or SOCRCVS instruction needs a 5119-word area (10238 bytes). Decreasing the receive data size enables effective use of the device.

- Preventing receive data from being divided

Depending on the line type, data to be received from the external device may be divided before arrival. In this case, specifying the receive data size in TCP/TLS fixed-length receive mode can prevent receive data from being divided.

- Preventing receive data from being connected

Due to a delay in receive processing of the sequence program, data which has been divided and sent may be connected before receiving depending on the external device.

Specifying the receive data size in TCP/TLS fixed-length receive mode enables data to be correctly divided and received.

- The size of the receive data to be read once by the SOCRCV instruction or SOCRCVS instruction is specified in (s2)+3. In the case of UDP/DTLS, if the received data exceeds the specified receive data size, the excess data becomes the next receive data.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |

When completed with an error, an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

 User's manual for the controller used

### Point

When the receive status signal does not turn on in TCP/TLS fixed-length receive mode, the data received as of the current time can be read with the SOCRDATA instruction to check whether the data sent from the external device is missing.

# Reading socket communications receive data

## G(P).SOCRDATA, S(P).SOCRDATA

These instructions read data by the number of words specified by (n) from the socket communications receive data area of the connection specified by (s1), and store them in the device specified by (d) and later.

## Processing details

These instructions read data by the number of words specified by (n) from the socket communications receive data area of the connection specified by (s1), and store them in the device specified by (d) and later. If the read data (n) is 0, no processing is performed.

### Point

- This instruction supports the encrypted predefined protocols (TLS and DTLS). For more details, check the user's manual for the controller used.
- The receive data length can be read by setting the number of read data to 1 word. As a result, the device for storing receive data when the SOCRCV instruction or SOCRCVS instruction is executed can be changed.
- After issuing this instruction to check the data to be received this time and issuing the SOCRCMODE instruction to specify the size of the data to be received next time, the SOCRCV instruction or SOCRCVS instruction can be used to read the data of this time. As a result, based on the data received this time, the size of data to be received next can be specified.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The connection number specified by (s1) is outside the range.                           |
| 3293H            | When the number of read data specified by (n) exceeds the maximum range.                |

When completed with an error, an error code is stored in the completion status (s2)+1.

For the error code stored in the completion status (s2)+1, refer to the following.

📖 User's manual for the controller used

# 29.3      Predefined Protocol Support Function Instruction

## Point

For connections where any of the following instructions is being executed, a request is ignored even if the following multiple instructions are attempted to be executed.

At this time, as long as the execution conditions of the instruction executed later are met, the request is executed after the first instruction being executed completes. SM699 (Dedicated instruction skip flag) turns on while the request is ignored.

- SOCOPEN instruction
- SOCCLOSE instruction
- SOCSND instruction
- SOCRCV instruction
- ECPRTCL instruction

## Executing the registered protocols

### GP.ECPRTCL, SP.ECPRTCL

This instruction executes the protocol registered using the engineering tool.

If the number of protocols executed is less than 8, "0" is stored. | 0, 1 to 16    | System |

## Processing details

- This instruction executes the protocol registered using the engineering tool. Using the connection specified by (s1), the instruction executes the protocol in accordance with the control data stored in the device specified by (s3) and later.
- The instruction continuously executes as many protocols as specified by (s2) (a maximum of 8 protocols) at one time.
- The number of executed protocols is stored in the device specified by (s3)+0.
- The protocol execution status can be checked with the predefined protocol support function execution status check area (Un\G350 to Un\G669). (User's manual for the controller used)
- The execution status and the completion status of this instruction can be checked with the completion device (d) specified by the setup data and the completion status indication device (d)+1.
- Completion device (d)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- The following figure shows the execution timing of this instruction.

- Protocol execution can be canceled by setting a protocol cancel request. The protocol cancel request is specified in the predefined protocol support function execution status check area (Un\G350 to Un\G669). (📖User's manual for the controller used)

- The following figure shows the protocol cancel operations from time to time.

- If a cancel request is issued before transmission

The following figure shows the operation when the protocol execution status is "1: Waiting for transmission".

- If a cancel request is issued before completion of transmission

The following figure shows the operation when transmission has not been completed while the protocol execution status is "2: Sending".

- If a cancel request is issued upon completion of transmission

The following figure shows the operation when transmission has been completed while the protocol execution status is "2: Sending".

- If a cancel request is issued while waiting for reception

The following figure shows the operation when the protocol execution status is "3: Waiting for data reception".

- If a cancel request is issued during receiving

The following figure shows the operation when the protocol execution status is "4: Receiving".

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | (s1) is outside the range.                                                              |

Upon completion with an error, the completion status indication device (d)+1 is turned on and an error code is stored in the completion status (s3)+1.

For the error code stored in the completion status (s3)+1, refer to the following.

 User's manual for the controller used

## Precautions

- If an error occurs in the mth protocol while multiple protocols are being executed, the instruction does not execute the "m+1"th protocol and after and is completed with an error.
- When a protocol including no-conversion variables is executed, the total data length of the variables used in one packet may exceed 1920 bytes. In this case, the instruction may obtain CPU device values over several scans. Therefore, do not change the CPU device values specified in non-conversion variables from the start of the instruction to the end of execution.
- Protocol cancellation
  - This instruction is completed with an error and stores the protocol cancel request error (C404H) in the device (completion status) specified by (s3)+1.
  - If a cancel request is issued while no protocol is being executed, the controller completes the cancel request without performing any processing.
  - While no communication protocol is used, any cancel request is ignored if issued.
  - When multiple protocols are executed continuously, a cancel request may be issued during execution of the nth protocol. In this case, the controller forcibly terminates the nth protocol and does not execute the subsequent protocols. Protocol number n being executed is stored in the device specified by ((s3)+0), the receive packet number successful in comparison match is stored in the device specified by 1 to (n-1), and the protocol cancel request error (C404H) is stored in the device specified by ((s3)+1).
  - The controller periodically checks for a cancel request. For this reason, it may take time until cancel processing is performed after a cancel request is issued.
- This instruction itself does not open/close a connection and therefore the SOCOPEN instruction/SOCCLOSE instructions need to be used to open/close the connection.

 Page 1146 GP.SOCOPEN, SP.SOCOPEN

 Page 1150 GP.SOCCLOSE, SP.SOCCLOSE

- If same instructions are executed for the same connection, the subsequent instruction is ignored and is not executed until the preceding instruction is completed.
- If the receive waiting time is set to "0: Infinite wait", this instruction is not completed until the data specified in the protocol setting is received.
- When "Send Only" is selected for the communication type, and data is sent to the external device by using TCP/IP protocol, the execution of this instruction is completed without checking the arrival of that data at the external device, and the completion status ((S3)+1) becomes completed successfully. Select "Send & Receive" for the communication type to check for the arrival of the sent data at the external device, so that a response from the external device is awaited before the instruction is completed.

# 29.4 SLMP Frame Send Instruction

## Sending an SLMP frame

### G(P).SLMPSND, J(P).SLMPSND, SP.SLMPSND

This instruction sends SLMP messages to the SLMP-compatible device.

- Point**
- The G(P).SLMPSND instruction can be used with the Ethernet port, CC-Link IE TSN port, and extension modules.
  - The J(P).SLMPSND instruction can be used with the CC-Link IE TSN port and extension modules.
  - The SP.SLMPSND instruction can be used only for the port for Ethernet.
