\*1 If (s1)+0 is set to "0: Without arrival check", receive data is not set. Set 0 in (s1)+0 in the following cases:

- When a command that does not return a response message is used
- When a response message is not referred to

\*2 If operand (U) is specified as 3E0H, 1 to 9 can be specified.

\*3 If operand (U) is specified as 3E0H, it is fixed to 0000H.

\*4 Give the serial numbers when sending several request messages to the same SLMP-compatible device. Serial numbers to be given are automatically numbered by the system.

For the serial number, refer to the following.

 SLMP Reference Manual

## Request frame

## ■Response frame

| Operand: (d1) |                             |                                                                                                                                                                                                                     |               |        |
|---------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| Device        | Item                        | Description                                                                                                                                                                                                         | Setting range | Set by |
| +0            | Response data length        | The data length from the end code to the response data is stored. (In units of bytes)                                                                                                                               | 2 to 2000     | System |
| +1            | End code                    | The result of command processing is stored.<br>In normal end, 0 is stored. In abnormal end, an error code set by the external device is stored.                                                                     | —             | System |
| +2 to +□      | Response data <sup>*1</sup> | Sets execution results for the request data.<br>For details on the request data, refer to the following.<br> SLMP Reference Manual | —             | System |

<sup>\*1</sup> The response data is stored in units of bytes sequentially from lower bytes. When an odd number of bytes of response data is received, the last response data is stored in the lower byte of the last data storage area.

## Processing details

- This instruction sends the request frame in the device specified by (s2) and later to the external device specified by the external device IP address in the control data. When a response message is received from the external device, it is stored in the device specified by (d1).
- This instruction uses UDP communications. Set the external device to use UDP.
- This instruction communicates in binary code. Match the setting of the external device also with the binary code.
- The execution status and the completion status of this instruction can be checked with the completion device (d2)+0 specified by the setup data and the completion status indication device (d2)+1.
- Completion device (d2)+0

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d2)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- When an odd number of bytes of response data is received, invalid data is stored in the upper byte of the device where the last response data is stored.

### ■Message format (3E/4E frame)

The following figures show the request data of 3E/4E frame and the response data in normal/abnormal end.

- Request message

- Response message (in normal end)

- Response message (in abnormal end)

The network number, station number, request destination module I/O number, and multidrop station number are stored to the information of the error responding station.

■Message format (station number extension frame)

The following figures show the request data of station number extension frame and the response data in normal/abnormal end.

• Request message

• Response message (in normal end)

• Response message (in abnormal end)

The network number, station number, request destination module I/O number, multidrop station number, 00 (fixed value), and extension station number are stored to the information of the error responding station.

**Ex.**

When sending "Read (command: 0401H)" (reading in units of words) which reads the value in D100 to D102

- The following example shows that request data is stored in (s2)+2 and later (3E/4E frame).

- The following example shows that response data is stored in (d1)+2 and later (3E/4E frame).

- The following example shows that request data is stored in (s2)+2 and later (station number extension frame).

- The following example shows that response data is stored in (d1)+2 and later (station number extension frame).

## Precautions

- During the execution of the SLMPSEND instruction, if another SLMPSEND instruction specifying the same channel is executed, the later instruction is ignored. At this time, as long as the execution conditions of the instruction are met, the request is executed after the first instruction being executed completes. SM699 (Dedicated instruction skip flag) turns on while the request is ignored.
- Specify the arrival monitoring time ((s1)+11) of the control data and monitoring timer ((s2)+1) of the request frame so that the arrival monitoring time  $\geq$  monitoring timer.

- (1) Request message  
 (2) Processing request from external device to request destination  
 (3) Processing response from request destination to external device  
 (4) Response message

### Point

This instruction is successfully completed even if the target device returns an abnormal response. When this instruction is completed successfully, the response is whether normal or abnormal can be identified by the end code of the response frame. When an abnormal response is returned, check the manual of the SLMP-compatible device being used and take corrective action.

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port. |
| 3285H            | The value set to (s1)+2 as own station channel is out of the range.                     |
|                  | The value set to (s2)+0 as the request data length is 0 or exceeds 2000.                |

Upon completion with an error, the completion status indication device (d2)+1 is turned on and an error code is stored in the completion status (s1)+1. For the error code stored in the completion status (s1)+1, refer to the following.

User's manual for the controller used

# Sending an encrypted SLMP frame

## G(P).SLMPSNDC

Sends encrypted SLMP messages to the SLMP-compatible device.

This instruction can be used with the Ethernet port and extension modules.

\*1 If (s1)+0 is set to "0: Without arrival check", receive data is not set. Set 0 in (s1)+0 in the following cases:

- When a command that does not return a response message is used
- When a response message is not referred to

\*2 Give the serial numbers when sending several request messages to the same SLMP-compatible device. Serial numbers to be given are automatically numbered by the system.

For the serial number, refer to the following.

 SLMP Reference Manual

## ■Request frame

| Operand: (s2) |                     |                                                                                                                                                                                                                                                                         |               |        |

## ■Response frame

| Operand: (d1) |                             |                                                                                                                                                 |               |        |
|---------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| Device        | Item                        | Description                                                                                                                                     | Setting range | Set by |
| +0            | Response data length        | The data length from the end code to the response data is stored. (In units of bytes)                                                           | 2 to 2000     | System |
| +1            | End code                    | The result of command processing is stored.<br>In normal end, 0 is stored. In abnormal end, an error code set by the external device is stored. | —             | System |
| +2 to +□      | Response data <sup>*1</sup> | Sets execution results for the request data.<br>(Some commands do not return response data.)                                                    | —             | System |

\*1 The response data is stored in units of bytes sequentially from lower bytes. When an odd number of bytes of response data is received, the last response data is stored in the lower byte of the last data storage area.

## Processing details

- This instruction sends the request frame in the device specified by (s2) and later to the external device specified by the external device IP address in the control data. When a response message is received from the external device, it is stored in the device specified by (d1).
- This instruction uses DTLS communications. Set the external device to use DTLS.
- This instruction communicates in binary code. Match the setting of the external device also with the binary code.
- The execution status and the completion status of this instruction can be checked with the completion device (d2)+0 specified by the setup data and the completion status indication device (d2)+1.
- Completion device (d2)+0

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d2)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- When an odd number of bytes of response data is received, invalid data is stored in the upper byte of the device where the last response data is stored.

### ■Message format (3E/4E frame)

The following figures show the request data of 3E/4E frame and the response data in normal/abnormal end.

- Request message

- Response message (in normal end)

- Response message (in abnormal end)

The network number, station number, request destination module I/O number, and multidrop station number are stored to the information of the error responding station.

## ■ Message format (station number extension frame)

The following figures show the request data of station number extension frame and the response data in normal/abnormal end.

### • Request message

### • Response message (in normal end)

### • Response message (in abnormal end)

The network number, station number, request destination module I/O number, multidrop station number, 00 (fixed value), and extension station number are stored to the information of the error responding station.

**Ex.**

When sending "Read (command: 0401H)" (reading in units of words) which reads the value in D100 to D102

- The following example shows that request data is stored in (s2)+2 and later (3E/4E frame).

- The following example shows that response data is stored in (d1)+2 and later (3E/4E frame).

- The following example shows that request data is stored in (s2)+2 and later (station number extension frame).

- The following example shows that response data is stored in (d1)+2 and later (station number extension frame).

## Precautions

- When executing some of this instructions concurrently, be careful to set the channels of this instruction not to overlap. This instruction specifying the same channels cannot be used concurrently. When the execution conditions of this instruction in the same channel are satisfied in the same sequence scan, only this instruction that has been executed first is enabled and the subsequent instructions are not executed. In addition, any subsequent instruction of the same channel setting as this instruction being executed is not executed. If the controller does not execute the processing of this instruction, SM699 (Dedicated instruction skip flag) turns on.
- Specify the arrival monitoring time  $((s1)+11)$  of the control data and monitoring timer  $((s2)+1)$  of the request frame so that the arrival monitoring time  $\geq$  monitoring timer.

### Point

This instruction is successfully completed even if the target device returns an abnormal response. When this instruction is completed successfully, the response is whether normal or abnormal can be identified by the end code of the response frame. When an abnormal response is returned, check the manual of the SLMP-compatible device being used and take corrective action.

## Operation error

| Error code (SD0) | Description                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1193H            | Different channels where serial numbers are given, having the same own station port number                                                                  |
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port.                                                                     |
| 3285H            | The value set to $(s1)+2$ as own station channel is out of the range, 1 to 9.<br>The value set to $(s2)+0$ as the request data length is 0 or exceeds 2000. |

Upon completion with an error, the completion status indication device  $(d2)+1$  is turned on and an error code is stored in the completion status  $(s1)+1$ . For the error code stored in the completion status  $(s1)+1$ , refer to the following.

User's manual for the controller used

# 29.5 File Transfer Function Instructions

## Sending FTP client files

### GP.FTPCPUT, SP.FTPPUT

Sends files in the controller, which are specified by (s2), to the folder path of the FTP server, which is specified by (s3).

## Processing details

- Sends files in the controller, which are specified by (s2), to the folder path of the FTP server, which is specified by (s3). The controller opens a connection with the FTP server set in the module parameters ("FTP Client Settings") at execution of this instruction, and closes a connection after sending files. For details on the parameter setting, refer to the following.

User's manual for the controller used

- The total number of files to be transferred by this instruction is stored in (s1)+2, and the number of transferred files is stored in (s1)+3.
- Specify the transfer source drive number (2 to 4, or 6) of the controller, the folder path where the files are stored, and the file name (including a period and an extension) in (s2) in Unicode string in 64 characters or less. The maximum number of characters used in a file path is 255. The maximum number of characters used in a path, excluding the file name, is 246 (not including a delimiter). Use one-byte '\' or '/' as a delimiter to specify the boundaries between the elements in a file path.

\*1

(1) Drive numbers that can be specified are 2 to 4, or 6. ( User's manual for the controller used)

(2) Use one-byte '\' or '/' as a delimiter of the drive number.

(3) Use one-byte '\' or '/' as a delimiter of the folder path and file.

(4) The specified file name should include an extension.

\*1 A relative path cannot be specified for the FTP client path.

- Wild card characters (\*, ?) can be used in the file name or the extension specified in (s2).

| Symbol | Description                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------|
| *      | An asterisk '*' is replaced with any character or string (including none) in a file name.                           |
| ?      | A question mark '?' is replaced with a character (excluding none) in a file name. ('?' can be used multiple times.) |

Wild card characters do not recognize periods.

Using wild card characters in the following ways results in an error.

- Two or more asterisks '\*\*' are used in a file name (before the period) or an extension. (Example: \*abc\*.txt)
- An asterisk '\*' and a question mark '?' are used in a file name (before the period) or an extension. (Example: \*ab?.txt)

When any wild card character is used, the number of files that can be transferred is determined by the total size of the file names of the specified files. The specified files can be transferred when the number of these files and the total size of the file names satisfy the following condition. If a file transfer function instruction is executed without satisfying the following condition, the instruction completes with an error.

$$(F_i + N \cdot M) + 1 < 65536 \text{ [bytes]}$$

N: Total number of files that match the wild card specification

F<sub>i</sub>: Total size of the file names that match the wild card specification

M: Specific information size (Fixed value: 6 bytes)

- If an error occurs in any one of the files to be transferred during execution of this instruction, the transfer processing will be stopped upon detection of the error, and the rest of the target files will not be transferred.
- Untransferable files will not be transferred even though the wild card specification conditions are satisfied.
- If the number of characters in the file path which includes a file name and an extension exceeds 255, files will not be transferred even though the wild card specification conditions are satisfied.

- Specify the folder path of the transfer destination FTP server in (s3) in Unicode string. The specified folder path shall be a relative path from home directory of the FTP server. Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path. \*1 The maximum number of characters used in the folder path is 255. Note that the total number of characters in a folder path (including the delimiter at the end) and the file name specified in (s2) must be within the maximum path length supported by the transfer destination FTP server. The delimiter at the end of a string can be omitted. When omitted, '\' is assumed to be set at the end. If a nonexistent folder path is specified, a folder is automatically created by the system at execution of the instruction, and then the processing is performed. \*2

—[... "\database1\recipe\" ...]—

(1) (2)

(1) Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path. \*3

(2) The delimiter at the end of string can be omitted.

\*2 FTP server drive cannot be specified.

\*3 Note that '\' cannot be used as a delimiter for some FTP servers.

- If a NULL character is specified by (s3) or only "0000H" is specified for the device, the controller directly accesses under the home directory of the FTP server. For details, follow the FTP server specifications.
- If a file with the same name exists in the transfer destination, the file will be overwritten.
- The maximum size of a file that can be sent is 4G bytes.
- The execution status and the completion status of this instruction can be checked with the completion device (d) specified by the setup data and the completion status indication device (d)+1.

• Completion device (d)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

• Completion status indication device (d)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing. In addition, an error code is stored in the device specified by (s1)+1.

- The following figure shows the execution timing of this instruction.

(1) SM1392 turns on during the END processing after the controller is connected to the FTP server.

(2) Values are stored upon completion of the instruction.

(3) When all files have been transferred, SM1392 turns off.

- SM1392 (FTP client connection status) is on while the controller is connected to the FTP server, and SM1392 turns off when disconnected.
- SM753 (File being accessed) turns on while this instruction is being executed. While SM753 is on, this instruction cannot be executed. If executed, no processing is performed.
- If this instruction is executed while this instruction, GP.FTPCGET instruction or SP.FTPGET instruction is being executed, the instruction is ignored and not executed until the currently executing instruction completes. When this instruction is ignored, SM699 (Dedicated instruction skip flag) turns on.
- In the following cases, the instruction completes with an error: when there is no free space in the transfer destination; or when b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), but there is not enough free space for storing transfer-target files and a temporary file (same size as transfer-target files) in the transfer destination.
- Even though the operating status of the controller is switched RUN to STOP during the file transfer processing, the controller continues the processing until completed.

## Precautions

- If a cable is disconnected, power is shut off, or the controller is reset during the file transfer processing, delete unnecessary files (such as a temporary file and undefined files) on the FTP server as needed. Then, transfer files again.
- When b2 (Transfer completion file delete setting) of (s1)+0 is set to 1 (Delete), note the following.

| Item                                                      | Description                                                                                                                   |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| When files in the controller are transferred              | Files required for the controller to operate are also deleted. If deleted, operations of the controller cannot be guaranteed. |
| When wild card characters are used to specify a file name | Required files may be deleted unintentionally.                                                                                |

- When transfer source file access is restricted by the file password function, this instruction completes with an error. Note, however, that this instruction can be executed if b2 (Transfer completion file delete setting) of (s1)+0 is set to 0 (Do not delete) and the file password setting type is "Write Protection".
- When b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), a temporary file of up to 68 characters (transfer source file name including period and extension.TMP) will be created in the transfer destination. Therefore, set the transfer destination folder path so that the total number of characters in the folder path and the temporary file does not exceed the maximum path length supported by the destination FTP server.
- Do not use any unsupported characters. If an unsupported character is included in the file name or the folder name specified by (s2) and (s3), the character is converted to "\_" and processed. When wild card characters are used and an unsupported character is included in the name of files stored in the transfer source controller, the character is converted to "\_" and processed. For this reason, the corresponding file is transferred in the same way as files having the same file name or folder name after character conversion are transferred.

## Operation error

| Error code (SD0) | Description                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port.                                                                     |
| 2820H            | There is no NULL code (0000H) in the assignment range of the relevant device/label for the device number specified by (s2), (s3), and later.                |
| 3285H            | The number of characters in the string specified by (s2) exceeds 255.                                                                                       |
|                  | The number of characters in the path specified by (s2), excluding the file name, exceeds 246 (not including a delimiter).                                   |
|                  | The total number of characters in the strings specified by (s2) (only the file name part, excluding the drive number and folder path) and (s3) exceeds 255. |
|                  | The drive number specified by (s2) is out of range.                                                                                                         |
|                  | The number of characters of the file name specified by (s2) exceeds 64.                                                                                     |
| 3296H            | A file name is not specified by (s2).                                                                                                                       |
|                  | The file name that cannot be transferred is specified by (s2).                                                                                              |
|                  | The delimiter used to separate the drive number in (s2) is neither ':' nor '/'.                                                                             |
|                  | Two or more asterisks '*' are used in the file name (before the period) or the extension specified by (s2).                                                 |
|                  | An asterisk '*' and a question mark '?' are used in the file name (before the period) or the extension specified by (s2).                                   |
| 329BH            | Wild card characters, '*' and '?', are used in the string specified by (s3).                                                                                |
|                  | This instruction was executed without setting FTP client parameters.                                                                                        |

Upon completion with an error, the completion status indication device (d)+1 is turned on and an error code is stored in the completion status (s1)+1.

For the error code stored in the completion status (s1)+1, refer to the following.

 User's manual for the controller used

# Retrieving FTP client files

29

## GP.FTPCGET, SP.FTPGET

Retrieves files on the FTP server, which are specified by (s2), to the folder path of the controller, which is specified by (s3).

| Ladder | ST                                                                            |

| +2            | Total number of files to be transferred | The total number of files to be transferred by this instruction is stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | —                                  | System |
| +3            | Number of transferred files             | The number of transferred files is stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | —                                  | System |

## Processing details

- Retrieves files on the FTP server, which are specified by (s2), to the folder path of the controller, which is specified by (s3). The controller opens a connection with the FTP server set in the module parameters ("FTP Client Settings") at execution of this instruction, and closes a connection after retrieving files. For details on the parameter setting, refer to the following.

📖 User's manual for the controller used

- The total number of files to be transferred by this instruction is stored in (s1)+2, and the number of transferred files is stored in (s1)+3.
- Specify the folder path where the transfer source files are stored on the FTP server, and the file names (including a period and an extension) in (s2) in Unicode string in 64 characters or less. The maximum number of characters used in a file path is 255. The specified file path shall be a relative path from home directory of the FTP server. Use one-byte '\' or '/' as a delimiter to specify the boundaries between the folder path and the file name. \*1\*2

(1) Use one-byte '\' or '/' as a delimiter of the folder path or file.\*2

(2) The specified file name should include an extension.

\*1 FTP server drive cannot be specified.

\*2 Note that '\' cannot be used as a delimiter for some FTP servers.

- Wild card characters (\*, ?) can be used in the file name or the extension specified in (s2).

| Symbol | Description                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------|
| *      | An asterisk '*' is replaced with any character or string (including none) in a file name.                           |
| ?      | A question mark '?' is replaced with a character (excluding none) in a file name. ('?' can be used multiple times.) |

Wild card characters do not recognize periods.

Using wild card characters in the following ways results in an error.

- Two or more asterisks '\*\*' are used in a file name (before the period) or an extension. (Example: \*abc\*.txt)
- An asterisk '\*' and a question mark '?' are used in a file name (before the period) or an extension. (Example: \*ab?.txt)

Files in the subfolder cannot be transferred.

When any wild card character is used, files to be retrieved differ depending on the FTP server environment. Check the operating specifications of the FTP server.

When any wild card character is used, the number of files that can be transferred is determined by the total size of the file names of the specified files. The specified files can be transferred when the number of these files and the total size of the file names satisfy the following condition. If a file transfer function instruction is executed without satisfying the following condition, the instruction completes with an error.

$(Fi + NM) + 1 < 65536$  [bytes]

N: Total number of files that match the wild card specification

Fi: Total size of the file names that match the wild card specification

M: Specific information size (Fixed value: 6 bytes)

- If an error occurs in any one of the files to be retrieved during execution of this instruction, the transfer processing will be stopped upon detection of the error, and the rest of the target files will not be transferred.
- Untransferable files will not be transferred even though the wild card specification conditions are satisfied.
- If the number of characters in the file path which includes a file name and an extension exceeds 255, files will not be transferred even though the wild card specification conditions are satisfied.
- If only a file name is specified by (s2), the controller directly accesses under the home directory of the FTP server. When specifying only a file name, start with a delimiter. For details, follow the FTP server specifications.
- Specify the folder path of the transfer destination of the controller in (s3) in Unicode string. Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path. The maximum number of characters in the folder path is 247 (246 when a delimiter at the end of the string is omitted). Note that the total number of characters in a folder path (including the delimiter at the end) and the file name specified in (s2) must be within the maximum path length (255 characters) supported by the controller. The delimiter at the end of a string can be omitted. When omitted, '\' is assumed to be set at the end. If a nonexistent folder path is specified, a folder is automatically created by the system at execution of the instruction, and then the processing is performed. \*3

- (1) Drive numbers that can be specified are 2 to 4. (User's manual for the controller used)  
 (2) Use one-byte '\' or '/' as a delimiter of the drive number.  
 (3) Use one-byte '\' or '/' as a delimiter to specify the boundary of the folder path.  
 (4) The delimiter at the end of string can be omitted.

\*3 A relative path cannot be specified for the FTP client path.

- If a file with the same name exists in the transfer destination, the file will be overwritten.
- The maximum size of a file that can be retrieved is 4G bytes.
- The execution status and the completion status of this instruction can be checked with the completion device (d) specified by the setup data and the completion status indication device (d)+1.

- Completion device (d)

This device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing.

- Completion status indication device (d)+1

This device turns on or off depending on the completion status of this instruction.

Completed successfully: The device remains off.

Completed with an error: The device turns on during END processing of the scan where this instruction completes, and turns off during the next END processing. In addition, an error code is stored in the device specified by (s1)+1.

- The following figure shows the execution timing of this instruction.

- (1) SM1392 turns on during the END processing after the controller is connected to the FTP server.  
 (2) Values are stored upon completion of the instruction.  
 (3) When all files have been transferred, SM1392 turns off.

- SM1392 (FTP client connection status) is on while the controller is connected to the FTP server, and SM1392 turns off when disconnected.
- SM753 (File being accessed) turns on while this instruction is being executed. While SM753 is on, this instruction cannot be executed. If executed, no processing is performed.
- If this instruction is executed while GP.FTPCPUT instruction, SP.FTPPUT instruction, or this instruction is being executed, the instruction is ignored and not executed until the currently executing instruction completes. When this instruction is ignored, SM699 (Dedicated instruction skip flag) turns on.
- In the following cases, the instruction completes with an error: when there is no free space in the transfer destination; or when b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), but there is not enough free space for storing transfer-target files and a temporary file (same size as transfer-target files) in the transfer destination.
- Even though the operating status of the controller is switched RUN to STOP during the file transfer processing, the controller continues the processing until completed.

## Precautions

- If a cable is disconnected, power is shut off, or the controller is reset during the file transfer processing, transfer files again. In those cases, unnecessary files will be deleted in the following ways.

| Unnecessary file                                                   | Delete operation                                                                                                                        |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Temporary file (transfer source file name including extension.TMP) | A temporary file left in the FTP client will be automatically deleted at the start of next file transfer processing to the same folder. |
| Undefined transfer target file                                     | An undefined transfer target file left in the FTP client will be overwritten during next file transfer processing to the same file.     |

- When a file with the same name has already existed in the transfer destination and its access is restricted by the file password function, this instruction completes with an error.
- When b3 (Temporary file create setting) of (s1)+0 is set to 0 (Create), set the maximum number of characters in the folder path of the controller to 243 (242 when a delimiter at the end of the string is omitted). Since a temporary file of up to 68 characters (transfer source file name including period and extension.TMP) is created in the transfer destination, set the transfer destination folder path so that the total number of characters in the folder path and the temporary file does not exceed the maximum path length (255 characters) supported by the controller.
- Do not use any unsupported characters. If an unsupported character is included in the file name or the folder name specified by (s2) and (s3), the character is converted to "\_" and processed. For this reason, the corresponding file is transferred in the same way as files having the same file name or folder name after character conversion are transferred. When wild card characters are used and an unsupported character is included in the name of files stored in the transfer source FTP server, files cannot be retrieved properly. (How to treat unsupported characters depends on the specifications of the FTP server.)

## Operation error

| Error code (SD0) | Description                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 2802H            | The Ethernet function instruction is executed using the settings with no Ethernet port.                                                      |
| 2820H            | There is no NULL code (0000H) in the assignment range of the relevant device/label for the device number specified by (s2), (s3), and later. |
| 3285H            | The number of characters in the string specified by (s2) exceeds 255.                                                                        |
|                  | The number of characters in the path specified by (s2), excluding the file name, exceeds 246 (not including a delimiter).                    |
|                  | The total number of characters in the strings specified by (s3) and (s2) (only the file name part) exceeds 255.                              |
|                  | The drive number specified by (s3) is out of range.                                                                                          |
|                  | The number of characters of the file name specified by (s2) exceeds 64.                                                                      |
| 3296H            | A file name is not specified by (s2).                                                                                                        |
|                  | The file name that cannot be transferred is specified by (s2).                                                                               |
|                  | The delimiter used to separate the drive number in (s3) is neither ':' nor '/'.                                                              |
|                  | Two or more asterisks '**' are used in the file name (before the period) or the extension specified by (s2).                                 |
|                  | An asterisk '*' and a question mark '?' are used in the file name (before the period) or the extension specified by (s2).                    |
| 329BH            | Wild card characters, '**' and '?', are used in the string specified by (s3).                                                                |
|                  | This instruction was executed without setting FTP client parameters.                                                                         |

Upon completion with an error, the completion status indication device (d)+1 is turned on and an error code is stored in the completion status (s1)+1.

For the error code stored in the completion status (s1)+1, refer to the following.

 User's manual for the controller used

# 30 EXTERNAL DEVICE COMMUNICATION INSTRUCTIONS

## 30.1 Special Adapter Instruction

### ADPRW

This instruction allows communications (read/write data) with slave stations using a function code supported by the master.

\*1 T, ST, and C cannot be used.

\*2 FX and FY cannot be used.

## Processing details

- Function code (s2) is operated on Slave station No. (s1) according to Parameters (s3), (s4), (s5), and (d1). Use 0 as the Slave station No. (s1) for Broadcast commands. (Page 1216 Function codes and function parameters)
- The communication execution status (d2) is output according to the status of the ADPRW instruction such as communicating/completed normally/completed with an error. (Page 1218 Communication execution status output device)
- The ADPRW instruction is executed using the channel specified in the communication channel (n).

## ■Operations other than the normal execution

The operation during an online change differs depending on whether the program file to be rewritten contains a communicating instruction.

- Rewriting the program file containing a communicating instruction: The subsequent operations are taken over with the communication processing. Therefore, the MODBUS RTU communicating SM devices (SM8800, SM8810) remain 1 (communicating). Then, the MODBUS RTU communicating SM devices are turned off if the communication completes with the communication processing, also turned off during the instruction execution of the communication execution status output device, and turned on if the instruction completes with an error. Note that, when executing read commands, the read data is not stored in the devices. If the drive contact of the ADPRW instruction is turned off during at least one scan, the operation does not resume even if the contact turns on in later scans, unless the previous communication completes with the communication processing.
- Rewriting the other program file: The operation is continued.

## ■Function codes and function parameters

The parameter assignment of (s3), (s4), (s5), and (d1) by each function code (s2) is shown below.

| (s2): Function code | (s3): MODBUS address                                       | (s4): Access points         | (s5): Start device storing write data<br>(d1): Start device storing read data |                                                                                                                         |

|                                         |                                                            |                             | Number of occupied points                                                     | (s4) points                                                                                                             |

\*1 The fraction is ignored.

\*2 The bit is turned off when the least significant bit is 0 and is turned on when the least significant bit is 1.

► Target device table

| No. | Target device                                                         |
|-----|-----------------------------------------------------------------------|
| ❶   | T, ST, C, D, R, W, SW, SD, LT, LST, LC, Z, LZ, ZR, label device       |
| ❷   | T, ST, C, D, R, W, SW, SD, LT, LST, LC, Z, LZ, ZR, label device, K, H |
| ❸   | X, Y, M, L, B, F, SB, SM, V, label device                             |

## ■Communication execution status output device

The following table lists the timing of operation of the communication execution status output device (d2) according to each communication status, as well as the special relays that operate simultaneously.

| Operand              | Timing of operation                                                    | Special relays that operate simultaneously |
|----------------------|------------------------------------------------------------------------|--------------------------------------------|
| (d2)                 | ON during instruction operation, OFF during other states               | SM8800 (CH1), SM8810 (CH2)                 |
| (d2)+1 <sup>*1</sup> | ON upon normal instruction completion, OFF at start of communication   | —                                          |
| (d2)+2 <sup>*1</sup> | ON upon abnormal instruction completion, OFF at start of communication | —                                          |

\*1 Normal and abnormal states can be distinguished as (d2)+1 turns on when the instruction is completed normally and (d2)+2 turns on when the instruction is completed abnormally.

## Precautions

- For the target channel to which the ADPRW instruction is to be used, configure the MODBUS master settings using GX Works3. Otherwise, the operation will not be performed even when the ADPRW instruction is executed. An operation error (error code: 3600H) will occur.
- When the program stops due to an error, the device value is turned off if a non-latch device is specified as the communication status output device. Specify a latch device if the communication status output needs to be retained.

## 30.2 Serial Communication 2

30

### RS2

This instruction sends/receives data by non-protocol communication via the communication adapter mounted on the controller.

| Ladder | Structured text                 |
|--------|---------------------------------|
|        | ENO:=RS2(EN, s, n1, n2, n3, d); |

### FBD/LD

### Setting data

#### ■Descriptions, ranges, and data types

| Operand | Description                      | Range     | Data type              | Data type (label) |
|---------|----------------------------------|-----------|------------------------|-------------------|
| (s)     | Head device storing send data    | —         | Word                   | ANY16             |
| (n1)    | Number of send data points       | 0 to 4096 | 16-bit unsigned binary | ANY16_U           |
| (d)     | Head device storing receive data | —         | Word                   | ANY16             |
| (n2)    | Number of receive data points    | 0 to 4096 | 16-bit unsigned binary | ANY16_U           |
| (n3)    | Communication channel            | K1, K2    | 16-bit unsigned binary | ANY16_U           |
| EN      | Execution condition              | —         | Bit                    | BOOL              |
| ENO     | Execution result                 | —         | Bit                    | BOOL              |

\*1 T, ST, and C cannot be used.

\*2 FX and FY cannot be used.

## Processing details

This instruction sends/receives data by non-protocol communication via the communication adapter mounted on the controller. This instruction specifies the head device storing the data sent from the controller, the number of data points, the head device storing the received data, and the maximum number of data points that can be received.

### ■Operations other than the normal execution

The operation during an online change differs depending on whether the program file to be rewritten contains a communicating instruction.

- Rewriting the program file containing a communicating instruction: The execution of the RS2 instruction is stopped.
- Rewriting the other program file: The operation is continued.

## Precautions

When changing the header, terminator, or timeout time, change them before driving the RS2 instruction (while it is off).

Changes are applied when the RS2 instruction is driven. Do not change the header, terminator, or timeout time while the RS2 instruction is being driven.

# 31 TYPE CONVERSION FUNCTIONS

## 31.1 Converting BOOL to WORD

### BOOL\_TO\_WORD(\_E)

These functions convert a value from BOOL data type to WORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BOOL_TO_WORD(s);<br>[With EN/ENO]<br>d:=BOOL_TO_WORD_E(EN,ENO,s); |
|  |  |                                                                                          |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | WORD      |

#### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BOOL data type to WORD data type, and output the converted value from (d).
- When the input value is FALSE, 0H (WORD data type) is output.
- When the input value is TRUE, 1H (WORD data type) is output.

- Input a BOOL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

There is no operation error.

# 31.2 Converting BOOL to DWORD

31

## BOOL\_TO\_DWORD(\_E)

These functions convert a value from BOOL data type to DWORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BOOL_TO_DWORD(s);<br>[With EN/ENO]<br>d:=BOOL_TO_DWORD_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DWORD     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BOOL data type to DWORD data type, and output the converted value from (d).
- When the input value is FALSE, 0H (DWORD data type) is output.
- When the input value is TRUE, 1H (DWORD data type) is output.

- Input a BOOL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.3 Converting BOOL to INT

## BOOL\_TO\_INT(\_E)

These functions convert a value from BOOL data type to INT data type.

| Ladder, FBD/LD   |               | ST                                                                                     |
|------------------|---------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=BOOL_TO_INT(s);<br>[With EN/ENO]<br>d:=BOOL_TO_INT_E(EN,ENO,s); |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (IN)   | Input                                                           | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d        | Output                                                          | Output variable | INT       |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BOOL data type to INT data type, and output the converted value from (d).
- When the input value is FALSE, 0 (INT data type) is output.
- When the input value is TRUE, 1 (INT data type) is output.

- Input a BOOL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.4 Converting BOOL to DINT

31

## BOOL\_TO\_DINT(\_E)

These instructions convert a value from BOOL data type to DINT data type.

| Ladder, FBD/LD   |               | ST                                                                                       |
|------------------|---------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=BOOL_TO_DINT(s);<br>[With EN/ENO]<br>d:=BOOL_TO_DINT_E(EN,ENO,s); |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (IN)   | Input                                                           | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d        | Output                                                          | Output variable | DINT      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BOOL data type to DINT data type, and output the converted value from (d).
- When the input value is FALSE, 0 (DINT data type) is output.
- When the input value is TRUE, 1 (DINT data type) is output.

- Input a BOOL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.5 Converting BOOL to TIME

## BOOL\_TO\_TIME(\_E)

These functions convert a value from BOOL data type to TIME data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BOOL_TO_TIME(s);<br>[With EN/ENO]<br>d:=BOOL_TO_TIME_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (IN)   | Input                                                           | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d        | Output                                                          | Output variable | TIME      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BOOL data type to TIME data type, and output the converted value from (d).
- When the input value is FALSE, 0 (TIME data type) is output.
- When the value is TRUE, 1 (TIME data type) is output.

- Input a BOOL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  |                     | Operation result              |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.6 Converting BOOL to STRING

31

## BOOL\_TO\_STRING(\_E)

These functions convert a value from BOOL data type to STRING data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                           |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BOOL_TO_STRING(s);<br>[With EN/ENO]<br>d:=BOOL_TO_STRING_E(EN,ENO,s); |
|  |  |                                                                                              |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (IN)   | Input                                                           | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d        | Output                                                          | Output variable | STRING    |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BOOL data type to STRING data type, and output the converted value from (d).
- When the input value is FALSE, 0 (STRING data type) is output.
- When the input value is TRUE, 1 (STRING data type) is output.

- Input a BOOL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.7 Converting WORD to BOOL

## WORD\_TO\_BOOL(\_E)

These functions convert a value from WORD data type to BOOL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=WORD_TO_BOOL(s);<br>[With EN/ENO]<br>d:=WORD_TO_BOOL_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | WORD      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | BOOL      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from WORD data type to BOOL data type, and output the converted value from (d).
- When the input value is 0H, FALSE is output.
- When the input value is other than 0H, TRUE is output.

- Input a WORD data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.8 Converting WORD to DWORD

31

## WORD\_TO\_DWORD(\_E)

These functions convert a value from WORD data type to DWORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=WORD_TO_DWORD(s);<br>[With EN/ENO]<br>d:=WORD_TO_DWORD_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | WORD      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DWORD     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from WORD data type to DWORD data type, and output the converted value from (d).
- After the data type is converted, the upper 16 bits are filled with 0s.

- Input a WORD data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.9 Converting WORD to INT

## WORD\_TO\_INT(\_E)

These functions convert a value from WORD data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |

|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=WORD_TO_STRING(s);<br>[With EN/ENO]<br>d:=WORD_TO_STRING_E(EN,ENO,s); |
|  |  |                                                                                              |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | WORD      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | STRING(4) |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from WORD data type to STRING data type, and output the converted value from (d).

- Input a WORD data type value to (s).
- When SM701 (Number of output characters selection) is off, 00H is stored at the end of the string.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  |         | Operation result              |
|----------------------|---------|-------------------------------|
| EN                   | ENO     | (d)                           |
| TRUE (executed)      | TRUE    | Operation result output value |
| FALSE (not executed) | FALSE*1 | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.13 Converting DWORD to BOOL

## DWORD\_TO\_BOOL(\_E)

These functions convert a value from DWORD data type to BOOL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DWORD_TO_BOOL(s);<br>[With EN/ENO]<br>d:=DWORD_TO_BOOL_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DWORD     |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | BOOL      |

### Processing details

#### Operation processing

- These functions convert the value input to (s) from DWORD data type to BOOL data type, and output the converted value from (d).
- When the input value is 0H, FALSE is output.
- When the input value is other than 0H, TRUE is output.

- Input a DWORD data type value to (s).

#### Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.14 Converting DWORD to WORD

## DWORD\_TO\_WORD(\_E)

These functions convert a value from DWORD data type to WORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DWORD_TO_WORD(s);<br>[With EN/ENO]<br>d:=DWORD_TO_WORD_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DWORD     |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | WORD      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from DWORD data type to WORD data type, and output the converted value from (d).
- The upper 16-bit data of the input value (DWORD data type) are discarded. (Refer to (1) in the figure below.)

- Input a DWORD data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Point

When the DWORD\_TO\_WORD(\_E) function is executed, the upper 16-bit data of the input value (DWORD data type) are discarded.

## Operation error

There is no operation error.

# 31.15 Converting DWORD to INT

## DWORD\_TO\_INT(\_E)

These functions convert a value from DWORD data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DWORD_TO_INT(s);<br>[With EN/ENO]<br>d:=DWORD_TO_INT_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DWORD     |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | INT       |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from DWORD data type to INT data type, and output the converted value from (d).
- The upper 16-bit data of the input value (DWORD data type) are discarded. (Refer to (1) in the figure below.)

- Input a DWORD data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Point

When the DWORD\_TO\_INT(\_E) function is executed, the upper 16-bit data of the input value (DWORD data type) are discarded.

## Operation error

There is no operation error.

# 31.16 Converting DWORD to DINT

## DWORD\_TO\_DINT(\_E)

These functions convert a value from DWORD data type to DINT data type.

| Ladder, FBD/LD                                                                                        |                                                                                                    | ST                                                                                         |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DWORD     |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | STRING(8) |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from DWORD data type to STRING data type, and output the converted value from (d).

- Input a DWORD data type value to (s).
- When SM701 (Number of output characters selection) is off, 00H is stored at the end of the string.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.19 Converting INT to BOOL

## INT\_TO\_BOOL(\_E)

These functions convert a value from INT data type to BOOL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=INT_TO_BOOL(s);<br>[With EN/ENO]<br>d:=INT_TO_BOOL_E(EN,ENO,s); |
|  |  |                                                                                        |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | BOOL      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from INT data type to BOOL data type, and output the converted value from (d).
- When the value 0 is input, FALSE is output.
- When the value other than 0 is input, TRUE is output.

- Input an INT data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  |         | Operation result              |
|----------------------|---------|-------------------------------|
| EN                   | ENO     | (d)                           |
| TRUE (executed)      | TRUE    | Operation result output value |
| FALSE (not executed) | FALSE*1 | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.20 Converting INT to WORD

## INT\_TO\_WORD(\_E)

These functions convert a value from INT data type to WORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|

|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DWORD     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from INT data type to DWORD data type, and output the converted value from (d).
- After the data type is converted, the upper 16 bits are filled with 0s.

- Input an INT data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.22 Converting INT to DINT

## INT\_TO\_DINT(\_E)

These functions convert a value from INT data type to DINT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=INT_TO_DINT(s);<br>[With EN/ENO]<br>d:=INT_TO_DINT_E(EN,ENO,s); |

|  |  |                                                                                      |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | WORD      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from INT data type to BCD (WORD) data type, and output the converted value from (d).

(1) Make sure to set them to "0".

- Input an INT data type value to (s) within the range of 0 to 9999.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                       |
|------------------|---------------------------------------------------|
| 3281H            | Data input to (s) is out of the range, 0 to 9999. |

31

# 31.24 Converting INT to REAL

## INT\_TO\_REAL(\_E)

These functions convert a value from INT data type to REAL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |

| s (IN)   | Input                                                     | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | REAL      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from INT data type to REAL data type, and output the converted value from (d).

- Input an INT data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.25 Converting INT to LREAL

## INT\_TO\_LREAL(\_E)

These functions convert a value from INT data type to LREAL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=INT_TO_LREAL(s);<br>[With EN/ENO]<br>d:=INT_TO_LREAL_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | LREAL     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from INT data type to LREAL data type, and output the converted value from (d).

- Input an INT data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.26 Converting INT to TIME

## INT\_TO\_TIME(\_E)

These functions convert a value from INT data type to TIME data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.27 Converting INT to STRING

## INT\_TO\_STRING(\_E)

These functions convert a value from INT data type to STRING data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=INT_TO_STRING(s);<br/>[With EN/ENO]<br/>d:=INT_TO_STRING_E(EN,ENO,s);</div> |
|  |  |                                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | STRING(6) |

## Processing details

### ■Operation processing

- These functions convert the value input to (s) from INT data type to STRING data type, and output the converted value from (d).

- Input an INT data type value to (s).
- As sign data, 20H (space) is stored if the input value is positive, and 2DH (-) is stored if the value is negative.
- If the number of digits in the input value is less than the number of significant digits, 20H (space) is stored for the upper digit(s).

### Ex.

When the value -123 is input

- When SM701 (Number of output characters selection) is off, 00H is stored at the end of the string (4th word).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

# 31.28 Converting DINT to BOOL

31

## DINT\_TO\_BOOL(\_E)

These functions convert a value from DINT data type to BOOL data type.

| Ladder, FBD/LD   |               | ST                                                                                       |
|------------------|---------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=DINT_TO_BOOL(s);<br>[With EN/ENO]<br>d:=DINT_TO_BOOL_E(EN,ENO,s); |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DINT      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | BOOL      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from DINT data type to BOOL data type, and output the converted value from (d).
- When the value 0 is input, FALSE is output.
- When the value other than 0 is input, TRUE is output.

- Input a DINT data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.29 Converting DINT to WORD

## DINT\_TO\_WORD(\_E)

These functions convert a value from DINT data type to WORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_WORD(s);<br>[With EN/ENO]<br>d:=DINT_TO_WORD_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DINT      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | WORD      |

### Processing details

#### Operation processing

- These functions convert the value input to (s) from DINT data type to WORD data type, and output the converted value from (d).
- The upper 16-bit data of the input value (DINT data type) are discarded. (Refer to (1) in the figure below.)

- Input a DINT data type value to (s).

#### Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Point

When the DINT\_TO\_WORD(\_E) function is executed, the upper 16-bit data of the input value (DINT data type) are discarded.

## Operation error

There is no operation error.

# 31.30 Converting DINT to DWORD

## DINT\_TO\_DWORD(\_E)

These functions convert a value from DINT data type to DWORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |

| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.31 Converting DINT to INT

## DINT\_TO\_INT(\_E)

These functions convert a value from DINT data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_INT(s);<br>[With EN/ENO]<br>d:=DINT_TO_INT_E(EN,ENO,s); |
|  |  |                                                                                        |

### Setting data

#### Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DINT      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | INT       |

### Processing details

#### Operation processing

- These functions convert the value input to (s) from DINT data type to INT data type, and output the converted value from (d).

- Input a DINT data type value to (s).

#### Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                                                      |
|------------------|----------------------------------------------------------------------------------|
| 3281H            | The 32-bit signed binary data input to (s) is out of the range, -32768 to 32767. |

# 31.32 Converting DINT to BCD

## DINT\_TO\_BCD(\_E)

These functions convert a value from DINT data type to BCD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_BCD(s);<br>[With EN/ENO]<br>d:=DINT_TO_BCD_E(EN,ENO,s); |
|  |  |                                                                                        |

### Setting data

#### Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DINT      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_BIT   |

### Processing details

#### Operation processing

- These functions convert the value input to (s) from DINT data type to BCD (DWORD) data type, and output the converted value from (d).

(1) Make sure to set them to "0".

- Input a DINT data type value to (s). When (d) is of WORD data type, the input value range is 0 to 9999. When (d) is of DWORD data type, the input value range is 0 to 99999999.
- WORD or DWORD data type can be specified for (d). BOOL data type cannot be specified.

## ■ Operation result

### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (d) is of WORD data type

| Error code (SD0) | Description                                                                      |
|------------------|----------------------------------------------------------------------------------|
| 3281H            | The 32-bit signed binary data input to (s) is out of the range, -32768 to 32767. |
|                  | Data input to (s) is out of the range, 0 to 9999.                                |

- When (d) is of DWORD data type

| Error code (SD0) | Description                                                             |
|------------------|-------------------------------------------------------------------------|
| 3281H            | Data in the device specified by (s) is out of the range, 0 to 99999999. |

# 31.33 Converting DINT to REAL

## DINT\_TO\_REAL(\_E)

These functions convert a value from DINT data type to REAL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_REAL(s);<br>[With EN/ENO]<br>d:=DINT_TO_REAL_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DINT      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | REAL      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from DINT data type to REAL data type, and output the converted value from (d).

- Input a DINT data type value to (s).
- The number of significant digits is about seven because a REAL data type value is processed in 32-bit single precision.
- If the integer value exceeds the range of -16777216 to 16777215, a rounding error occurs in the converted value.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.34 Converting DINT to LREAL

31

## DINT\_TO\_LREAL(\_E)

These functions convert a value from DINT data type to LREAL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_LREAL(s);<br>[With EN/ENO]<br>d:=DINT_TO_LREAL_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | DINT      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | LREAL     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from DINT data type to LREAL data type, and output the converted value from (d).

- Input a DINT data type value to (s).
- The number of significant digits is about 15 because an LREAL data type value is processed in 64-bit double precision.
- If the integer value exceeds the range of -2147483648 to 2147483647, a rounding error occurs in the converted value.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.35 Converting DINT to TIME

## DINT\_TO\_TIME(\_E)

These functions convert a value from DINT data type to TIME data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_TIME(s);<br>[With EN/ENO]<br>d:=DINT_TO_TIME_E(EN,ENO,s); |

|----------|-----------------------------------------------------------|-----------------|------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL       |
| s (IN)   | Input                                                     | Input variable  | DINT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL       |
| d        | Output                                                    | Output variable | STRING(11) |

## Processing details

### ■Operation processing

- These functions convert the value input to (s) from DINT data type to STRING data type, and output the converted value from (d).

- Input a DINT data type value to (s).
- As sign data, 20H (space) is stored if the input value is positive, and 2DH (-) is stored if the value is negative.
- If the number of digits in the input value is less than the number of significant digits, 20H (space) is stored for the upper digit(s).

#### Ex.

When the value -123456 is input

- When SM701 (Number of output characters selection) is off, 00H is stored at the end of the string (upper bytes of the 6th word).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

# 31.37 Converting BCD to INT

## BCD\_TO\_INT(\_E)

These functions convert a value from BCD data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                 |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=BCD_TO_INT(s);<br/>[With EN/ENO]<br/>d:=BCD_TO_INT_E(EN,ENO,s);</div> |
|  |  |                                                                                                    |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | WORD      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | INT       |

## Processing details

### ■Operation processing

- These functions convert the value input to (s) from BCD (WORD) data type to INT data type, and output the converted value from (d).

- (1) Thousands place
- (2) Hundreds place
- (3) Tens place
- (4) Ones place
- (5) Always becomes "0".

- Input a WORD data type value to (s) within the range of 0H to 9999H (range of each digit: 0 to 9).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                              |
|------------------|--------------------------------------------------------------------------|
| 3281H            | A value other than 0 to 9 exists at any digit of the value input to (s). |

Turning on SM754 can prevent the above error from being issued. If the specified value is out of the valid range, the BCD\_TO\_INT(\_E) function is not executed regardless of the status (on/off) of SM754.

# 31.38 Converting BCD to DINT

## BCD\_TO\_DINT(\_E)

These functions convert a value from BCD data type to DINT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BCD_TO_DINT(s);<br>[With EN/ENO]<br>d:=BCD_TO_DINT_E(EN,ENO,s); |
|  |  |                                                                                        |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_BIT   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DINT      |

## Processing details

### ■Operation processing

- These functions convert the value input to (s) from BCD (WORD or DWORD) data type to DINT data type, and output the converted value from (d).
- When (s) is of WORD data type

(1) Always becomes "0".

- When (s) is of DWORD data type

(1) Always becomes "0".

- Input a WORD data type value within the range of 0H to 9999H (range of each digit: 0 to 9) or a DWORD data type value within the range of 0H to 99999999H (range of each digit: 0 to 9) to (s).
- WORD or DWORD data type can be specified for (s). BOOL data type cannot be specified.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

| Error code (SD0) | Description                                                              |
|------------------|--------------------------------------------------------------------------|
| 3281H            | A value other than 0 to 9 exists at any digit of the value input to (s). |

Turning on SM754 can prevent the above error from being issued. If the specified value is out of the valid range, the BCD\_TO\_DINT(\_E) function is not executed regardless of the status (on/off) of SM754.

# 31.39 Converting BCD to STRING

## BCD\_TO\_STRING(\_E)

These functions convert a value from BCD data type to STRING data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BCD_TO_STRING(s);<br>[With EN/ENO]<br>d:=BCD_TO_STRING_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_BIT   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | STRING(8) |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from BCD (WORD or DWORD) data type to STRING data type, and output the converted value from (d).
- When (s) is of WORD data type

- When (s) is of DWORD data type

- WORD or DWORD data type can be specified for (s). BOOL data type cannot be specified.
- When SM701 (Number of output characters selection) is off, 00H is stored at the end of the string.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  |                     | Operation result              |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s) is of WORD data type

| Error code (SD0) | Description                                       |
|------------------|---------------------------------------------------|
| 3281H            | Data input to (s) is out of the range, 0 to 9999. |

- When (s) is of DWORD data type

| Error code (SD0) | Description                                                             |
|------------------|-------------------------------------------------------------------------|
| 3281H            | Data in the device specified by (s) is out of the range, 0 to 99999999. |

# 31.40 Converting REAL to INT

## REAL\_TO\_INT(\_E)

These functions convert a value from REAL data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|

# 31.41 Converting REAL to DINT

## REAL\_TO\_DINT(\_E)

These functions convert a value from REAL data type to DINT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=REAL_TO_DINT(s);<br>[With EN/ENO]<br>d:=REAL_TO_DINT_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | REAL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DINT      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from REAL data type to DINT data type, and output the converted value from (d).

- Input a REAL data type value to (s) within the range of -2147483648 to 2147483647.
- After conversion, the first digit after the decimal point of the input value (REAL data type) is rounded off.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | The single-precision real number input to (s) is out of the range, -2147483648 to 2147483647.                                                                                                                                                                                                                                                                                                                                                                                                  |
| 3282H            | <ul style="list-style-type: none"> <li>An unusual number is set to (s).</li> <li>The single-precision real number input to (s) is not within the following range:<br/> <math>-2^{128} &lt; (s) \leq -2^{-126}</math>, 0, <math>2^{-126} \leq (s) &lt; 2^{128}</math><br/>           (E-3.40282347+38 to E-1.17549435-38, 0, E1.17549435-38 to E3.40282347+38)</li> <li>The value set to a device or label is -0, a subnormal number, NaN (not a number), or <math>\pm\infty</math>.</li> </ul> |

# 31.42 Converting REAL to LREAL

## REAL\_TO\_LREAL(\_E)

These functions convert a value from REAL data type to LREAL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=REAL_TO_LREAL(s);<br>[With EN/ENO]<br>d:=REAL_TO_LREAL_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | REAL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | LREAL     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from REAL data type to LREAL data type, and output the converted value from (d).

- Input a REAL data type value to (s).
- The number of significant digits is about seven because a REAL data type value is processed in 32-bit single precision.
- If the integer value exceeds the range of -16777216 to 16777215, a rounding error occurs in the converted value.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

| Error code<br>(SD0) | Description                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3282H               | The data input to (s) is -0 or out of the following range.<br>$-2^{128} < (s) \leq -2^{-126}$ , 0, $2^{-126} \leq (s) < 2^{128}$<br>(E-3.40282347+38 to E-1.17549435-38, 0, E1.17549435-38 to E3.40282347+38) |

# 31.43 Converting REAL to STRING

## REAL\_TO\_STRING(\_E)

These functions converts a REAL data type value to STRING data type (exponential form).

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=REAL_TO_STRING(s);</div> <div>[With EN/ENO]<br/>d:=REAL_TO_STRING_E(EN,ENO,s);</div> |
|  |  |                                                                                                                   |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type  |
|----------|-----------------------------------------------------------|-----------------|------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL       |
| s (IN)   | Input                                                     | Input variable  | REAL       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL       |
| d        | Output                                                    | Output variable | STRING(13) |

## Processing details

### ■Operation processing

- These functions convert the value input to (s) from REAL data type to STRING data type (exponential form), and output the converted value from (d).

- Input a REAL data type value to (s).
- The converted string data is output from (d) as follows.
  - The number of digits for an integral part, decimal part, and exponent is fixed, integral part: one digit; decimal part: five digits; exponent: two digits.
  - As the second byte, 20H (space) is stored; as the fourth byte, 2EH (.) is stored; and as the 10th byte, 45H (E) is stored automatically.

- As sign data (for integral part), 20H (space) is stored if the input value is positive, and 2DH (-) is stored if the input value is negative.
- The sixth and later digits of the decimal part are rounded off.

- If the number of digits in the input value is less than the number of significant digits, 30H (0) is stored in the decimal part.

- As sign data (for exponent), 2BH (+) is stored if the input value is positive, and 2DH (-) is stored if the input value is negative.
- When the exponent is one digit, 30H (0) is stored in the tens place of the exponent.

- The NULL code (00H) is automatically stored at the end (i.e. seventh word) of the converted string.

■Operation result

1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 3286H            | The entire string after conversion cannot be stored in the label or device area (between the specified device number and the last device number) specified by (d). (The number of required points is insufficient.)                                                                                                                                                                                                         |

# 31.44 Converting LREAL to INT

31

## LREAL\_TO\_INT(\_E)

These functions convert a value from LREAL data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=LREAL_TO_INT(s);<br>[With EN/ENO]<br>d:=LREAL_TO_INT_E(EN,ENO,s); |
|  |  |                                                                                          |

### Setting data

#### Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | LREAL     |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | INT       |

### Processing details

#### Operation processing

- These functions convert the value input to (s) from LREAL data type to INT data type, and output the converted value from (d).

- Input an LREAL data type value to (s).
- After conversion, the first digit after the decimal point of the input value (LREAL data type) is rounded off.

#### Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | LREAL     |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DINT      |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from LREAL data type to DINT data type, and output the converted value from (d).

- Input an LREAL data type value to (s).
- After conversion, the first digit after the decimal point of the input value (LREAL data type) is rounded off.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

# 31.49 Converting TIME to DWORD

## TIME\_TO\_DWORD(\_E)

These functions convert a value from TIME data type to DWORD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=TIME_TO_DWORD(s);<br>[With EN/ENO]<br>d:=TIME_TO_DWORD_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | TIME      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DWORD     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from TIME data type to DWORD data type, and output the converted value from (d).

- Input a TIME data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.50 Converting TIME to INT

31

## TIME\_TO\_INT(\_E)

These functions convert a value from TIME data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=TIME_TO_INT(s);<br>[With EN/ENO]<br>d:=TIME_TO_INT_E(EN,ENO,s); |
|  |  |                                                                                        |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (IN)   | Input                                                           | Input variable  | TIME      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d        | Output                                                          | Output variable | INT       |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from TIME data type to INT data type, and output the converted value from (d).

- Input a TIME data type value to (s).
- The upper 16-bit data of the input value (TIME data type) are discarded.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.51 Converting TIME to DINT

## TIME\_TO\_DINT(\_E)

These functions convert a value from TIME data type to DINT data type.

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from TIME data type to STRING data type, and output the converted value from (d).

- Input a TIME data type value to (s).
- When SM701 (Number of output characters selection) is off, 00H is stored at the end of the string.
- The operation result will be as follows.
  - As the first character, 20H (space) is stored if the output value is positive, and 2DH (-) is stored if the output value is negative.
  - At the left of the number of significant digits, 20H (space) is stored.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

## STRING\_TO\_DWORD(\_E)

These functions convert a value from STRING data type to DWORD data type.

| Ladder, FBD/LD   |               | ST                                                                                             |
|------------------|---------------|------------------------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=STRING_TO_DWORD(s);<br>[With EN/ENO]<br>d:=STRING_TO_DWORD_E(EN,ENO,s); |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | STRING(8) |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | DWORD     |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from STRING data type to DWORD data type, and output the converted value from (d).

- Input a STRING data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                                  |
|------------------|--------------------------------------------------------------|
| 3281H            | An ASCII code other than 30H to 39H and 41H to 46H is input. |

# 31.56 Converting STRING to INT

## STRING\_TO\_INT(\_E)

These functions convert a value from STRING data type to INT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=STRING_TO_INT(s);<br>[With EN/ENO]<br>d:=STRING_TO_INT_E(EN,ENO,s); |
|  |  |                                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | STRING(6) |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | INT       |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from STRING data type to INT data type, and output the converted value from (d).

- Input a STRING data type value to (s) within the following range.
  - ASCII code: 30H to 39H, 20H, 2DH, and 00H
  - STRING data type value: -32768 to 32767

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

| Error code (SD0) | Description                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | Invalid data that cannot be converted are input in (s). <ul style="list-style-type: none"> <li>• ASCII code: other than 30H to 39H, 20H, and 00H</li> <li>• STRING data type value: other than -32768 to 32767</li> </ul> |

# 31.57 Converting STRING to DINT

## STRING\_TO\_DINT(\_E)

These functions convert a value from STRING data type to DINT data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                           |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=STRING_TO_DINT(s);<br>[With EN/ENO]<br>d:=STRING_TO_DINT_E(EN,ENO,s); |
|  |  |                                                                                              |

### Setting data

#### Description, type, data type

| Argument | Description                                               | Type            | Data type  |
|----------|-----------------------------------------------------------|-----------------|------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL       |
| s (IN)   | Input                                                     | Input variable  | STRING(11) |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL       |
| d        | Output                                                    | Output variable | DINT       |

### Processing details

#### Operation processing

- These functions convert the value input to (s) from STRING data type to DINT data type, and output the converted value from (d).

- Input a STRING data type value to (s) within the following range.
- ASCII code: 30H to 39H, 20H, 2DH, and 00H
- STRING data type value: -2147483648 to 2147483647

#### Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

| Error code (SD0) | Description                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# 31.58 Converting STRING to BCD

## STRING\_TO\_BCD(\_E)

These functions convert a value from STRING data type to BCD data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=STRING_TO_BCD(s);<br/>[With EN/ENO]<br/>d:=STRING_TO_BCD_E(EN,ENO,s);</div> |
|  |  |                                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | STRING(8) |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_BIT   |

## Processing details

### ■Operation processing

- These functions convert the value input to (s) from STRING data type to BCD (WORD) data type, and output the converted value from (d).

- The ASCII code 20H (space) that exists in the string is ignored.
- The ASCII codes 20H (space) and 30H (0) that exist in the string are counted as one character as well.
- Input a STRING data type value to (s) within the following range.  
ASCII code: 30H to 39H, 20H, 00H
- If the string input has less than four characters, the string will be supplemented with zero(s). (Zero(s) is/are added at the end of the string.) For this reason, if a string shorter than four characters is to be converted, input a string padded with 0s (e.g. '0001' for '1').
- If the string length exceeds 4 characters, the four left characters are regarded as the targets to convert.

| Input string | Conversion target string | Output (BCD data type) |
|--------------|--------------------------|------------------------|
| '1'          | '1000'                   | 1000H (4096D)          |
| '12'         | '1200'                   | 1200H (4608D)          |
| '123'        | '1230'                   | 1230H (4656D)          |
| '1234'       | '1234'                   | 1234H (4660D)          |
| '12345'      | '1234'                   | 1234H (4660D)          |

- WORD or DWORD data type can be specified for (d). BOOL data type cannot be specified.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                |
|------------------|------------------------------------------------------------|
| 3281H            | An ASCII code other than 30H to 39H, 20H, or 00H is input. |

# 31.59 Converting STRING to REAL

## STRING\_TO\_REAL(\_E)

These functions convert a value from STRING data type to REAL data type.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=STRING_TO_REAL(s);</div> <div>[With EN/ENO]<br/>d:=STRING_TO_REAL_E(EN,ENO,s);</div> |
|  |  |                                                                                                                   |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type  |
|----------|-----------------------------------------------------------|-----------------|------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL       |
| s (IN)   | Input                                                     | Input variable  | STRING(24) |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL       |
| d        | Output                                                    | Output variable | REAL       |

## Processing details

### ■ Operation processing

- These functions convert the value input to (s) from STRING data type (decimal form/exponential form) to REAL data type, and output the converted value from (d).

- The STRING data type value both in decimal form and exponential form can be converted.
- When (s) is in decimal form

- When (s) is in exponential form

- The number of significant digits of the STRING data type value is six. (The sign, decimal point, and exponent are not included.) The seventh and later digits are rounded down when the data is converted.

- When (s) is in decimal form

- When (s) is in exponential form

- In decimal form, when 2BH (+) is specified as sign data or the sign data is omitted, the data is converted as a positive value. When 2DH (-) is specified, the data is converted as a negative value.
- In exponential form, when 2BH (+) is specified as sign data for the exponent or the sign data is omitted, the data is converted as a positive value. When 2DH (-) is specified, the data is converted as a negative value.
- The ASCII code 20H (space) or 30H (0) that exists before the first numerical value 0 in the STRING data type value is ignored.
- When (s) is in decimal form

- When (s) is in exponential form

- The ASCII code 30H (0) that exists between E and a numerical value in the STRING data type value is ignored (in exponential form only).

- The ASCII code 20H (space) that exists in the string is ignored.
- Up to 24 characters can be input. The ASCII codes 20H (space) and 30H (0) that exist in the string are counted as one character as well.
- Input a STRING data type value to (s) within the following range.
  - ASCII code: 30H to 39H, 45H, 2BH, 2DH, 2EH, 20H, and 00H

## ■ Operation result

### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# 31.60 Converting STRING to TIME

31

## STRING\_TO\_TIME(\_E)

These functions convert a value from STRING data type to TIME data type.

| Ladder, FBD/LD   |               | ST                                                                                           |
|------------------|---------------|----------------------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=STRING_TO_TIME(s);<br>[With EN/ENO]<br>d:=STRING_TO_TIME_E(EN,ENO,s); |
|                  |               |                                                                                              |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type  |
|----------|-----------------------------------------------------------|-----------------|------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL       |
| s (IN)   | Input                                                     | Input variable  | STRING(11) |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL       |
| d        | Output                                                    | Output variable | TIME       |

### Processing details

#### ■Operation processing

- These functions convert the value input to (s) from STRING data type to TIME data type, and output the converted value from (d).

- Input a STRING data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | An ASCII code other than 30H to 39H, 20H, and 00H is input.<br>The STRING data type value input is out of the following range:<br>-2147483648 to 2147483647 |

# 31.61 Converting Bit Array to INT

## BITARR\_TO\_INT(\_E)

These functions convert the specified number of bits in a bit array to an INT data type value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                             |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=BITARR_TO_INT(s,n);<br>[With EN/ENO]<br>d:=BITARR_TO_INT_E(EN,ENO,s,n); |
|  |  |                                                                                                |

### Setting data

#### ■Description, type, data type

| Argument   | Description                                                     | Type            | Data type             |
|------------|-----------------------------------------------------------------|-----------------|-----------------------|
| EN         | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL                  |
| s (BitArr) | Input (An element can be specified by a variable.)              | Input variable  | Boolean array element |
| n          | Number of bits (4, 8, 12, or 16)                                | Input variable  | INT                   |
| ENO        | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL                  |
| d          | Output                                                          | Output variable | ANY16                 |

### Processing details

#### ■Operation processing

- These functions convert the number of bits specified by (n) starting from the bit array element input to (s) to ANY16 type data, and output the converted value from (d).
- Zeros (0s) are set for all the bits exceeding the specified number of bits.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.62 Converting Bit Array to DINT

31

## BITARR\_TO\_DINT(\_E)

These functions convert the specified number of bits in a bit array to a DINT data type value.

| Ladder, FBD/LD   |               | ST                                                                                                                        |
|------------------|---------------|---------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br><code>d:=BITARR_TO_DINT(s,n)</code><br>[With EN/ENO]<br><code>d:=BITARR_TO_DINT_E(EN,ENO,s,n);</code> |

### Setting data

#### ■Description, type, data type

| Argument   | Description                                                     | Type            | Data type             |
|------------|-----------------------------------------------------------------|-----------------|-----------------------|
| EN         | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL                  |
| s (BitArr) | Input (An element can be specified by a variable.)              | Input variable  | Boolean array element |
| n          | Number of bits (4, 8, 12, 16, 20, 24, 28, or 32)                | Input variable  | INT                   |
| ENO        | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL                  |
| d          | Output                                                          | Output variable | ANY32                 |

### Processing details

#### ■Operation processing

- These functions convert the number of bits specified by (n) starting from the bit array element input to (s) to ANY32 type data, and output the converted value from (d).
- Zeros (0s) are set for all the bits exceeding the specified number of bits.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.63 Converting INT to Bit Array

## INT\_TO\_BITARR(\_E)

These functions output the lower n bits of the INT data type value to the bit array.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                             |

### Processing details

#### ■Operation processing

- These functions output the lower (n) bits of ANY16 type data specified by (s) to (d).
- The output bits beyond the specified number of bits are not changed.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.64 Converting DINT to Bit Array

## DINT\_TO\_BITARR(\_E)

These functions output the lower n bits of the DINT data type value to the bit array.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                               |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DINT_TO_BITARR(s,n);<br>[With EN/ENO]<br>d:=DINT_TO_BITARR_E(EN,ENO,s,n); |
|  |  |                                                                                                  |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type             |
|----------|-----------------------------------------------------------------|-----------------|-----------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL                  |
| s        | Input                                                           | Input variable  | ANY32                 |
| n        | Number of bits (4, 8, 12, 16, 20, 24, 28, or 32)                | Input variable  | BOOL                  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL                  |
| d        | Output (An element can be specified by a variable.)             | Output variable | Boolean array element |

### Processing details

#### ■Operation processing

- These functions output the lower (n) bits of ANY32 type data specified by (s) to (d).
- The output bits beyond the specified number of bits are not changed.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.65 Copying the Bit Array

## CPY\_BITARR(\_E)

These functions copy the bit array by the specified number of bits.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=CPY_BITARR(s,n);<br>[With EN/ENO]<br>d:=CPY_BITARR_E(EN,ENO,s,n); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument    | Description                                                     | Type            | Data type             |
|-------------|-----------------------------------------------------------------|-----------------|-----------------------|

| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

# 31.66 Reading the Specified Bit of the Word Label

31

## GET\_BIT\_OF\_INT(\_E)

These functions read a value from the specified bit of a word label.

| Ladder <sup>*1</sup>                                                              |                                                                                   | ST                                                                                               |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=GET_BIT_OF_INT(s,n);<br>[With EN/ENO]<br>d:=GET_BIT_OF_INT_E(EN,ENO,s,n); |
|  |  |                                                                                                  |

\*1 FBD/LD is not supported. For FBD/LD, use the bit specification of labels.

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type         |
|----------|-----------------------------------------------------------------|-----------------|-------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL              |
| s        | Input                                                           | Input variable  | INT <sup>*1</sup> |
| n        | Number of bits (0 to 15)                                        | Input variable  | INT               |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL              |
| d        | Output                                                          | Output variable | BOOL              |

\*1 Digit-specified labels and devices cannot be used.

### Processing details

#### ■Operation processing

These functions output a value in the (n)th bit of (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

There is no operation error.

By using the bit specification of labels, a concise program having the same operation as GET\_BIT\_OF\_INT can be created.

The following example reads the value in bit 5 (b5) of g\_int1 into g\_bool1 the same as when GET\_BIT\_OF\_INT is used.

Ladder

ST

```
g_bool1 := g_int1.5;
```

FBD/LD

# 31.67 Writing the Specified Bit of the Word Label

## SET\_BIT\_OF\_INT(\_E)

These functions write a value to the specified bit of a word label.

| Ladder <sup>*1</sup>                                                              |                                                                                   | ST                                                                                               |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=SET_BIT_OF_INT(s,n);<br>[With EN/ENO]<br>d:=SET_BIT_OF_INT_E(EN,ENO,s,n); |
|  |  |                                                                                                  |

\*1 FBD/LD is not supported. For FBD/LD, use the bit specification of labels.

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type                  | Data type         |
|----------|-----------------------------------------------------------------|-----------------------|-------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable        | BOOL              |
| s        | Input                                                           | Input variable        | BOOL              |
| n        | Number of bits (0 to 15)                                        | Input variable        | INT               |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable       | BOOL              |
| d        | Input/output                                                    | Input/output variable | INT <sup>*1</sup> |

\*1 Digit-specified labels and devices cannot be used.

### Processing details

#### ■Operation processing

These functions write a BOOL data type value specified by (s) to the (n)th bit of (d).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Precautions

When using SET\_BIT\_OF\_INT(\_E) in ST, create a program which assigns the return value to a variable.

//The return value of SET\_BIT\_OF\_INT is assigned to a variable and used.

```
g_int1 := SET_BIT_OF_INT(TRUE, 0);
```

```
g_bool1 := GET_BIT_OF_INT(g_int1, 0);
```

The return value of SET\_BIT\_OF\_INT(\_E) also works as input/output. Do not directly assign it to the input argument of another instruction, function, or function block.

//In the following program, the value of the first argument of GET\_BIT\_OF\_INT is undefined.

```
g_bool1 := GET_BIT_OF_INT( SET_BIT_OF_INT(TRUE, 0), 0);
```

## Operation error

There is no operation error.

### Point

By using the bit specification of labels, a concise program having the same operation as SET\_BIT\_OF\_INT can be created.

The following example changes the value in bit 5 (b5) of g\_int1 to the value of g\_bool1 the same as when SET\_BIT\_OF\_INT is used.

Ladder

ST

```
g_int1.5 := g_bool1;
```

FBD/LD

# 31.68 Copying the Specified Bit of the Word Label

31

## CPY\_BIT\_OF\_INT(\_E)

These functions copy the specified bit of the word label to the specified bit of another word label.

| Ladder <sup>*1</sup> |               | ST                                                                                                       |
|----------------------|---------------|----------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]     | [With EN/ENO] | [Without EN/ENO]<br>d:=CPY_BIT_OF_INT(s,n1,n2);<br>[With EN/ENO]<br>d:=CPY_BIT_OF_INT_E(EN,ENO,s,n1,n2); |
|                      |               |                                                                                                          |

\*1 FBD/LD is not supported. For FBD/LD, use the bit specification of labels.

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type                  | Data type         |
|----------|-----------------------------------------------------------------|-----------------------|-------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable        | BOOL              |
| s        | Input                                                           | Input variable        | INT <sup>*1</sup> |
| n1       | Number of bits in input variable (0 to 15)                      | Input variable        | INT               |
| n2       | Number of bits in output variable (0 to 15)                     | Input variable        | INT               |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable       | BOOL              |
| d        | Input/output                                                    | Input/output variable | INT <sup>*1</sup> |

\*1 Digit-specified labels and devices cannot be used.

### Processing details

#### ■Operation processing

These functions copy the value in the (n1)th bit of the word specified by (s) to the (n2)th bit of (d).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Precautions

When using CPY\_BIT\_OF\_INT(\_E) in ST, create a program which assigns the return value to a variable.

//The return value of CPY\_BIT\_OF\_INT is assigned to a variable and used.

```
g_int2 := CPY_BIT_OF_INT(g_int1,5,3);
```

```
g_bool1 := GET_BIT_OF_INT(g_int2,3);
```

The return value of CPY\_BIT\_OF\_INT(\_E) also works as input/output. Do not directly assign it to the input argument of another instruction, function, or function block.

//In the following program, the value of the first argument of GET\_BIT\_OF\_INT is undefined.

```
g_bool1 := GET_BIT_OF_INT( CPY_BIT_OF_INT(g_int1,5,3), 3);
```

## Operation error

There is no operation error.

### Point

By using the bit specification of labels, a concise program having the same operation as CPY\_BIT\_OF\_INT can be created.

The following example changes the value in bit 3 (b3) of g\_int2 to the value of bit 5 (b5) of g\_int1 the same as when CPY\_BIT\_OF\_INT is used.

Ladder

ST

```
g_int2.3 := g_int1.5;
```

FBD/LD

# 31.69 Getting the Start Data

## GET\_BOOL\_ADDR, GET\_INT\_ADDR, GET\_WORD\_ADDR

These functions output the start data of the specified array as BOOL, INT, or WORD type data.

| Ladder, FBD/LD                                                                    | ST                                                                 |
|-----------------------------------------------------------------------------------|--------------------------------------------------------------------|
|  | d:=GET_BOOL_ADDR(s)<br>d:=GET_INT_ADDR(s);<br>d:=GET_WORD_ADDR(s); |

### Setting data

#### ■Description, type, data type

| Argument | Description | Type            | Data type     |
|----------|-------------|-----------------|---------------|
| s        | Input       | Input variable  | ANY           |
| d        | Output      | Output variable | BOOL/INT/WORD |

### Processing details

#### ■Operation processing

- The GET\_BOOL\_ADDR function outputs the start data of the array specified by (s) as BOOL type data.
- The GET\_INT\_ADDR function outputs the start data of the array specified by (s) as INT type data. When the data type whose bit length is 32 bits or longer is specified, the lower 16 bits are acquired.
- The GET\_WORD\_ADDR function outputs the start data of the array specified by (s) as WORD type data. When the data type whose bit length is 32 bits or longer is specified, the lower 16 bits are acquired.

| Standard function | Input data type                                                                                                                              | Output data type |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| GET_BOOL_ADDR     | BOOL<br>ARRAY OF BOOL                                                                                                                        | BOOL             |
| GET_INT_ADDR      | INT                                                                                                                                          | INT              |
| GET_WORD_ADDR     | DINT<br>WORD<br>REAL<br>TIME<br>STRING<br>ARRAY OF INT<br>ARRAY OF DINT<br>ARRAY OF WORD<br>ARRAY OF DWORD<br>ARRAY OF REAL<br>ARRAY OF TIME | WORD             |

#### ■Operation result

The operation processing is performed. The operation result is output from (d).

### Operation error

There is no operation error.

# 32 SINGLE VARIABLE FUNCTIONS

## 32.1 Calculating the Absolute Value

### ABS(\_E)

These functions output the absolute value of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=ABS(s);<br>[With EN/ENO]<br>d:=ABS_E(EN,ENO,s); |
|  |  |                                                                        |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_NUM   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_NUM   |

#### Processing details

#### ■Operation processing

- These functions output the absolute value of the INT, DINT, REAL, or LREAL data type value input to (s), in the same type of data as (s), from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = |A|$
- Input an INT, DINT, REAL, or LREAL data type value to (s).
- If -32768 in INT data type is input to (s), (d) will output -32768.
- If -2147483648 in DINT data type is input to (s), (d) will output -2147483648. (No operation error occurs. When ABS\_E is used, ENO outputs TRUE.)

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s) is of REAL data type

| Error code (SD0) | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| 3282H            | The value output from (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |

- When (s) is of LREAL data type

| Error code (SD0) | Description                                                                               |
|------------------|-------------------------------------------------------------------------------------------|
| 3282H            | The value output from (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |

## 32.2 Calculating the Square Root

### SQRT(\_E)

These functions calculate the square root of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=SQRT(s);<br>[With EN/ENO]<br>d:=SQRT_E(EN,ENO,s); |
|  |  |                                                                          |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

#### Processing details

#### ■Operation processing

- These functions calculate the square root of the REAL/LREAL data type value input to (s) and store the operation result in (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:

$$B = \sqrt{A}$$

- Input a positive REAL/LREAL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

| Error code (SD0) | Description                  |
|------------------|------------------------------|
| 3285H            | The input value is negative. |

## 32.3 Calculating the Natural Logarithm

32

### LN(\_E)

These functions output the natural logarithm (logarithm with base e) of an input value.

| Ladder, FBD/LD   |               | ST                                                                   |
|------------------|---------------|----------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=LN(s);<br>[With EN/ENO]<br>d:=LN_E(EN,ENO,s); |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

#### Processing details

#### ■Operation processing

- These functions calculate the natural logarithm of the REAL/LREAL data type value input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = \log_e A$
- Natural logarithm operation is performed with the base (e) defined as 2.71828.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

| Error code (SD0) | Description                       |
|------------------|-----------------------------------|
| 3285H            | The input value is 0 or negative. |

## 32.4 Calculating the Common Logarithm

### LOG(\_E)

These functions output the common logarithm (logarithm with base 10) of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=LOG(s);<br>[With EN/ENO]<br>d:=LOG_E(EN,ENO,s); |
|  |  |                                                                        |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

### Processing details

#### ■Operation processing

- These functions calculate the common logarithm with base 10 of the REAL or LREAL data type value input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  

$$B = \log_{10} A$$
- Input a REAL or LREAL data type value to (s).
- Input a positive value only. (Calculation cannot be performed with a negative value.)
- If the operation result is -0 or an underflow occurs, 0 will be output as the operation result.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s) is of REAL data type

| Error code (SD0) | Description                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                                                                              |
| 3285H            | Out-of-range data is set to (s). <ul style="list-style-type: none"> <li>• The specified value is a negative number.</li> <li>• The specified value is 0.</li> </ul> |

- When (s) is of LREAL data type

| Error code (SD0) | Description                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                                                                              |
| 3285H            | Out-of-range data is set to (s). <ul style="list-style-type: none"> <li>• The specified value is a negative number.</li> <li>• The specified value is 0.</li> </ul> |

## 32.5 Calculating the Exponent

### EXP(\_E)

These functions output the exponent of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=EXP(s);<br>[With EN/ENO]<br>d:=EXP_E(EN,ENO,s); |
|  |  |                                                                        |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

### Processing details

#### ■Operation processing

- These functions calculate the exponent of the REAL/LREAL data type value input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  

$$B = e^A$$
- Exponent operation is performed with the base (e) defined as 2.71828.
- Input a REAL or LREAL data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .               |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ d  < 2^{128}$ |

## 32.6 Calculating the Sine

32

### SIN(\_E)

These functions output the sine of an input value.

| Ladder, FBD/LD   |               | ST                                                                     |
|------------------|---------------|------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=SIN(s);<br>[With EN/ENO]<br>d:=SIN_E(EN,ENO,s); |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

#### Processing details

#### ■Operation processing

- These functions calculate the sine of the REAL data type value (angle) input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:

$$B = \sin A$$

- Input a REAL data type value to (s). Input a value (angle) in radians ( $\text{angle} \times \pi / 180$ ).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

| Error code (SD0) | Description                      |
|------------------|----------------------------------|
| 3282H            | The data specified by (s) is -0. |

## 32.7 Calculating the Cosine

### COS(\_E)

These functions output the cosine of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=COS(s);<br>[With EN/ENO]<br>d:=COS_E(EN,ENO,s); |
|  |  |                                                                        |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

#### Processing details

#### ■Operation processing

- These functions calculate the cosine of the REAL data type value (angle) input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = \cos A$
- Input a REAL data type value to (s). Input a value (angle) in radians ( $\text{angle} \times \pi / 180$ ).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

| Error code (SD0) | Description                      |
|------------------|----------------------------------|
| 3282H            | The data specified by (s) is -0. |

## 32.8 Calculating the Tangent

### TAN(\_E)

These functions output the tangent of an input value.

| Ladder, FBD/LD   |               | ST                                                                     |
|------------------|---------------|------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=TAN(s);<br>[With EN/ENO]<br>d:=TAN_E(EN,ENO,s); |

#### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

#### Processing details

#### ■Operation processing

- These functions calculate the tangent of the REAL data type value (angle) input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = \tan A$
- Note that even if the input value is  $\pi/2$  radian or  $(3/2)\pi$  radian, no error will be issued because of the truncation error in the radian value.
- Input a REAL data type value to (s). Input a value (angle) in radians ( $\text{angle} \times \pi / 180$ ).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

| Error code (SD0) | Description                      |
|------------------|----------------------------------|
| 3282H            | The data specified by (s) is -0. |

## 32.9 Calculating the Arc Sine

### ASIN(\_E)

These functions output the arc sine ( $\text{SIN}^{-1}$ ) of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=ASIN(s);<br>[With EN/ENO]<br>d:=ASIN_E(EN,ENO,s); |
|  |  |                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

### Processing details

#### ■Operation processing

- These functions calculate the arc sine ( $\text{SIN}^{-1}$ ) of the REAL data type value input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = \text{SIN}^{-1} A$
- Input a REAL data type value to (s) within the following range.  
 ASIN(\_E): -1.0 to 1.0
- The value (angle) is output from (d) in radians ( $\text{angle} \times \pi / 180$ ).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                              |
|------------------|----------------------------------------------------------|
| 3282H            | The data specified by (s) is -0.                         |
| 3285H            | The value input with ASIN(_E) is other than -1.0 to 1.0. |

## 32.10 Calculating the Arc Cosine

32

### ACOS(\_E)

These functions output the arc cosine ( $\text{COS}^{-1}$ ) of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=ACOS(s);<br>[With EN/ENO]<br>d:=ACOS_E(EN,ENO,s); |
|  |  |                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

### Processing details

#### ■Operation processing

- These functions calculate the arc cosine ( $\text{COS}^{-1}$ ) of the REAL data type value input to (s), and output the operation result from (d).

- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = \text{COS}^{-1} A$

- Input a REAL data type value to (s) within the following range.

ACOS(\_E): -1.0 to 1.0

- The value (angle) is output from (d) in radians ( $\text{angle} \times \pi / 180$ ).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                                              |
|------------------|----------------------------------------------------------|
| 3282H            | The data specified by (s) is -0.                         |
| 3285H            | The value input with ACOS(_E) is other than -1.0 to 1.0. |

# 32.11 Calculating the Arc Tangent

## ATAN(\_E)

These functions output the arc tangent ( $\text{TAN}^{-1}$ ) of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=ATAN(s);<br>[With EN/ENO]<br>d:=ATAN_E(EN,ENO,s); |
|  |  |                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_REAL  |

### Processing details

#### ■Operation processing

- These functions calculate the arc tangent ( $\text{TAN}^{-1}$ ) of the REAL data type value input to (s), and output the operation result from (d).
- When the input value is defined as A and the output value is defined as B, the relationship of A and B will be as follows:  
 $B = \text{TAN}^{-1} A$
- Input a REAL data type value to (s) within the following range.  
 $\text{ATAN}(\_E): \pm 1.17549 \times 10^{-38} \text{ to } \pm 3.40282 \times 10^{38}$
- The value (angle) is output from (d) in radians ( $\text{angle} \times \pi / 180$ ).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

### Operation error

| Error code (SD0) | Description                      |
|------------------|----------------------------------|
| 3282H            | The data specified by (s) is -0. |

# 33 ARITHMETIC OPERATION FUNCTIONS

33

## 33.1 Addition

### ADD(\_E)

These functions output the sum of input values  $((s1)+(s2)+\dots+(s28))$ .

| Ladder, FBD/LD <sup>*1</sup>                                                      |                                                                                   | ST <sup>*1</sup>                                                                                         |

## Processing details

### ■Operation processing

- These functions add the INT, DINT, WORD, DWORD, REAL, or LREAL data type values input to (s1) to (s28) ((s1)+(s2)+...+(s28)), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: INT

- Input an INT, DINT, WORD, DWORD, REAL, or LREAL data type value to (s1) to (s28).
- If an underflow or overflow occurs in the operation result, the output from (d) will be as follows.

| Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INT       | <p>Even if an underflow or overflow occurs, no operation error is issued. When ADD_E is used, ENO outputs TRUE.</p> <p>[Example 1]</p> <p>32767+2=-32767<br/>(7FFFH)+(0002H)=(8001H)<br/>A negative value results because the most significant bit is 1.</p> <p>[Example 2]</p> <p>-32767+(-2)=32766<br/>(8000H)+(FFFEH)=(7FFEH)<br/>A positive value results because the most significant bit is 0.</p>                                         |
| DINT      | <p>Even if an underflow or overflow occurs, no operation error is issued. When ADD_E is used, ENO outputs TRUE.</p> <p>[Example 1]</p> <p>2147483647+2=-2147483647<br/>(7FFFFFFFH)+(00000002H)=(80000001H)<br/>A negative value results because the most significant bit is 1.</p> <p>[Example 2]</p> <p>-2147483648+(-2)=2147483646<br/>(80000000H)+(FFFEH)=(7FFFFFFEH)<br/>A positive value results because the most significant bit is 0.</p> |

| REAL      | An operation error occurs and an undefined value is output.                                                                                                                                                                                                                                                                                                                                                                                      |
| LREAL     |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s1) to (s28) are of REAL data type

| Error code (SD0) | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) to (s28) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .              |
|                  | The value output from (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                     |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ (\text{d})  < 2^{128}$ |

- When (s1) to (s28) are of LREAL data type

| Error code (SD0) | Description                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) to (s28) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .               |
|                  | The value output from (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .                      |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ (\text{d})  < 2^{1024}$ |

# 33.2 Multiplication

## MUL(\_E)

These functions output the product of input values ((s1)×(s2)×...×(s28)).

| Ladder, FBD/LD*1                                                                  |                                                                                   | ST*1                                                                           |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=MUL(s1,s2);<br>[With EN/ENO]<br>d:=MUL_E(EN,ENO,s1,s2); |
|  |  |                                                                                |

\*1 The input variable s can be changed within the range from 2 to 28.

| REAL<br>LREAL | An operation error occurs and an undefined value is output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### ■ Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

If the operation result is outside the data type range, convert the input value as appropriate before operation.

## Operation error

- When (s1) to (s28) are of REAL data type

| Error code (SD0) | Description                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) to (s28) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .         |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ < d >  < 2^{128}$ |

- When (s1) to (s28) are of LREAL data type

| Error code (SD0) | Description                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) to (s28) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .          |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ < d >  < 2^{1024}$ |

# 33.3 Subtraction

## SUB(\_E)

These functions output the difference between input values ((s1)-(s2)).

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                  |

### Setting data

#### ■Description, type, data type

| Argument           | Description                                               | Type            | Data type |
|--------------------|-----------------------------------------------------------|-----------------|-----------|
| EN                 | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1), s2 (IN2) | Input                                                     | Input variable  | ANY_NUM   |
| ENO                | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d                  | Output                                                    | Output variable | ANY_NUM   |

## Processing details

### ■Operation processing

- These functions perform subtraction between the INT, DINT, WORD, DWORD, REAL, or LREAL data type values input to (s1) and (s2) ((s1)-(s2)), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: INT

- Input an INT, DINT, WORD, DWORD, REAL, or LREAL data type value to (s1) and (s2).
- If an underflow or overflow occurs in the operation result, the output from (d) will be as follows.

| Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INT       | <p>Even if an underflow or overflow occurs, no operation error is issued. When SUB_E is used, ENO outputs TRUE.</p> <p>[Example 1]</p> <p>32767-(-2)=-32767<br/>(7FFFH)-(FFFEH)=(8001H)<br/>A negative value results because the most significant bit is 1.</p> <p>[Example 2]</p> <p>-32767-2=32766<br/>(8000H)-(0002H)=(7FFE H)<br/>A positive value results because the most significant bit is 0.</p>                                            |
| DINT      | <p>Even if an underflow or overflow occurs, no operation error is issued. When SUB_E is used, ENO outputs TRUE.</p> <p>[Example 1]</p> <p>2147483647-(-2)=-2147483647<br/>(7FFFFFFFH)-(0000FFFEH)=(80000001H)<br/>A negative value results because the most significant bit is 1.</p> <p>[Example 2]</p> <p>-2147483648-2=2147483646<br/>(80000000H)-(00000002H)=(7FFFFFFEH)<br/>A positive value results because the most significant bit is 0.</p> |
| WORD      | <p>Even if an underflow occurs, no operation error is issued. When ADD_E is used, ENO outputs TRUE.</p> <p>[Example]</p> <p>0 - 1 = 65535<br/>(0000H) - (0001H) = (FFFFH)</p>                                                                                                                                                                                                                                                                        |
| DWORD     | <p>Even if an underflow occurs, no operation error is issued. When ADD_E is used, ENO outputs TRUE.</p> <p>[Example]</p> <p>0 - 1 = 4294967295<br/>(00000000H) - (00000001H) = (FFFFFFFFH)</p>                                                                                                                                                                                                                                                       |
| REAL      | An operation error occurs and an undefined value is output.                                                                                                                                                                                                                                                                                                                                                                                          |
| LREAL     |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s1) and (s2) are of REAL data type

| Error code (SD0) | Description                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .              |
|                  | The value input to (s2) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .              |
|                  | The value output from (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .            |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ d  < 2^{128}$ |

- When (s1) and (s2) are of LREAL data type

| Error code (SD0) | Description                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .               |
|                  | The value input to (s2) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .               |
|                  | The value output from (d) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ .             |
| 3283H            | The data output from (d) exceeds the following range. (An overflow has occurred.)<br>$ d  < 2^{1024}$ |

# 33.4 Division

## DIV(\_E)

These functions output the quotient of input values ((s1)÷(s2)).

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                             |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=DIV(s1,s2);<br>[With EN/ENO]<br>d:=DIV_E(EN,ENO,s1,s2); |
|  |  |                                                                                |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1) | Dividend                                                  | Input variable  | ANY_NUM   |
| s2 (IN2) | Divisor                                                   | Input variable  | ANY_NUM   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_NUM   |

### Processing details

#### ■Operation processing

- These functions perform division between the INT, DINT, WORD, DWORD, REAL, or LREAL data type values input to (s1) and (s2) ((s1)÷(s2)), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: INT

- Input an INT, DINT, WORD, DWORD, REAL, or LREAL data type value to (s1) and (s2). (Note that the value input to (s2) shall be other than 0.)

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s1) and (s2) are of INT or WORD data type

| Error code (SD0) | Description                             |
|------------------|-----------------------------------------|
| 3280H            | The value (divisor) input to (s2) is 0. |

- When (s1) and (s2) are of DINT or DWORD data type

| Error code (SD0) | Description                             |
|------------------|-----------------------------------------|
| 3280H            | The value (divisor) input to (s2) is 0. |

- When (s1) and (s2) are of REAL data type

| Error code (SD0) | Description                                                                                                                                                                        |

## Setting data

### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1) | Dividend                                                  | Input variable  | ANY_INT   |
| s2 (IN2) | Divisor                                                   | Input variable  | ANY_INT   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_INT   |

## Processing details

### ■ Operation processing

- These functions perform division between the INT, DINT, WORD, or DWORD data type values input to (s1) and (s2) ((s1)÷(s2)), and output the remainder of the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: INT

- Input an INT, DINT, WORD, or DWORD data type value to (s1) and (s2). (Note that the value input to (s2) shall be other than 0.)

### ■ Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s1) and (s2) are of INT or WORD data type

| Error code (SD0) | Description                             |
|------------------|-----------------------------------------|
| 3280H            | The value (divisor) input to (s2) is 0. |

- When (s1) and (s2) are of DINT or DWORD data type

| Error code (SD0) | Description                             |
|------------------|-----------------------------------------|
| 3280H            | The value (divisor) input to (s2) is 0. |

# 33.6 Exponentiation

## EXPT(\_E)

These functions output the exponentiation of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                    |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=EXPT(s1,s2);</div> <div>[With EN/ENO]<br/>d:=EXPT_E(EN,ENO,s1,s2);</div> |
|  |  |                                                                                                       |

## Setting data

### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1) | Base                                                      | Input variable  | ANY_REAL  |
| s2 (IN2) | Exponent (power)                                          | Input variable  | ANY_NUM   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_REAL  |

## Processing details

### ■Operation processing

These functions exponentiate the REAL or LREAL data type value input to (s1) with the exponent (INT, DINT, REAL, or LREAL data type) input to (s2), and output the operation result from (d).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------|
| 3282H            | The value input to (s1) or (s2) is -0, a subnormal number, NaN (not a number), or $\pm\infty$ . |

# 33.7 Assignment (Move Operation)

## MOVE(\_E)

These functions output the assignment value of an input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=MOVE(s);<br>[With EN/ENO]<br>d:=MOVE_E(EN,ENO,s); |
|  |  |                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY       |

## Processing details

### ■Operation processing

- These functions assign the value of the input variable specified by (s) to the output variable specified by (d).
- Input a BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, TIME, structure, or array data type value to (s) and (d). The values input to (s) and (d) must be of the same data type.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 3285H            | The number of characters in the string input to (s) exceeds 16383.                                                                                                                             |
| 3286H            | From the device numbers specified in (d) onward, the specified string cannot be fully stored in each setting area of the device/label memory. (The number of required points is insufficient.) |

# 34 BIT SHIFT FUNCTIONS

## 34.1 Shifting Data to the Left by n Bit(s)

### SHL(\_E)

These functions shift the input value to the left by (n) bit(s), and output the operation result.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=SHL(s,n);<br/>[With EN/ENO]<br/>d:=SHL_E(EN,ENO,s,n);</div> |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_BIT   |
| n (N)    | Number of bits to be shifted                              | Input variable  | ANY_BIT   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_BIT   |

## Processing details

### ■Operation processing

- These functions shift the 16-bit data or 32-bit data (WORD or DWORD data type value) input to (s) to the left by (n) bit(s), and output the operation result, in the same data type as (s), from (d).
- Specify the number of bits to be shifted in (n).

**Ex.**

Data type of (s): 16-bit data (WORD data type), Value input to (n): 8

- The (n) bit(s) from the least significant bit is/are filled with 0(s).
- Input a 16-bit data or 32-bit data (WORD or DWORD data type value) to (s).
- Input a value to (n) (Number of bits to be shifted) within the following range.

| Data type of (s): 16-bit data (WORD data type)                                                                            | Data type of (s): 32-bit data (DWORD data type)                                                                            |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Range: 0 to 15<br>The lower 4-bit data is used.<br>[Example]<br>If the input value is 6: 6<br>If the input value is 22: 6 | Range: 0 to 31<br>The lower 5-bit data is used.<br>[Example]<br>If the input value is 6: 6<br>If the input value is 22: 22 |

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

# 34.2 Shifting Data to the Right by n Bit(s)

## SHR(\_E)

These functions shift the input value to the right by (n) bit(s), and output the operation result.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                         |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_BIT   |
| n (N)    | Number of bits to be shifted                              | Input variable  | ANY_BIT   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_BIT   |

## Processing details

### ■Operation processing

- These functions shift the 16-bit data or 32-bit data (WORD or DWORD data type value) input to (s) to the right by (n) bit(s), and output the operation result, in the same data type as (s), from (d).
- Specify the number of bits to be shifted in (n).

**Ex.**

Data type of (s): 16-bit data (WORD data type), Value input to (n): 8

- The (n) bit(s) from the most significant bit is/are filled with 0(s).
- Input a 16-bit data or 32-bit data (WORD or DWORD data type value) to (s).
- Input a value to (n) (Number of bits to be shifted) within the following range.

| Data type of (s): 16-bit data (WORD data type)                                                                            | Data type of (s): 32-bit data (DWORD data type)                                                                            |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Range: 0 to 15<br>The lower 4-bit data is used.<br>[Example]<br>If the input value is 6: 6<br>If the input value is 22: 6 | Range: 0 to 31<br>The lower 5-bit data is used.<br>[Example]<br>If the input value is 6: 6<br>If the input value is 22: 22 |

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

# 34.3 Rotating Data to the Left by n Bit(s)

## ROL(\_E)

These functions rotate the input value to the left by (n) bit(s), and output the operation result.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                         |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=ROL(s,n);<br>[With EN/ENO]<br>d:=ROL_E(EN,ENO,s,n); |
|  |  |                                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s (IN)   | Input                                                     | Input variable  | ANY_BIT   |
| n (N)    | Number of bits to be shifted                              | Input variable  | ANY_BIT   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY_BIT   |

## Processing details

### ■Operation processing

- These functions rotate the 16-bit data or 32-bit data (WORD or DWORD data type value) input to (s) to the left by (n) bit(s), and output the operation result, in the same data type as (s), from (d).
- Specify the number of bits to be rotated in (n).

#### Ex.

Data type of (s): 16-bit data (WORD data type), Value input to (n): 3 (The data rotates to the left by 3 bits.)

- Input a 16-bit data or 32-bit data (WORD or DWORD data type value) to (s).
- Input a value to (n) (Number of bits to be shifted) within the following range.

| Data type of (s): 16-bit data (WORD data type)                                                                            | Data type of (s): 32-bit data (DWORD data type)                                                                            |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Range: 0 to 15<br>The lower 4-bit data is used.<br>[Example]<br>If the input value is 6: 6<br>If the input value is 22: 6 | Range: 0 to 31<br>The lower 5-bit data is used.<br>[Example]<br>If the input value is 6: 6<br>If the input value is 22: 22 |

|  |  |                                                                                                                                                                                      |

\*1    The input variable s can be changed within the range from 2 to 28.

### Setting data

#### ■Description, type, data type

| Argument               | Description                                               | Type            | Data type |
|------------------------|-----------------------------------------------------------|-----------------|-----------|
| EN                     | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1) to s28 (IN28) | Input                                                     | Input variable  | ANY_BIT   |
| ENO                    | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d                      | Output                                                    | Output variable | ANY_BIT   |

## Processing details

### ■ Operation processing

#### 1. AND(\_E)

These functions perform an AND operation (bit-by-bit) on the BOOL, WORD, or DWORD data type values input to (s1) to (s28), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: WORD

#### 2. OR(\_E)

These functions perform an OR operation (bit-by-bit) on the BOOL, WORD, or DWORD data type values input to (s1) to (s28), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: WORD

#### 3. XOR(\_E)

- These functions perform an XOR operation (bit-by-bit) on the BOOL, WORD, or DWORD data type values input to (s1) to (s28), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: WORD

- If three or more (s) settings exist, (s3) will be XORed with the result of XOR between (s1) and (s2). In addition, if (s4) exists, (s4) will be XORed with the result of XOR for (s3). After this, XOR will repeat for the number of (s) settings.

**Ex.**

Data type: BOOL

- Number of s's: 3
- Number of s's: 4
- Number of s's: 5
- The XOR operation is repeated by the number of s's.

## ■Operation result

### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

## 35.2 NOT Operation

### NOT(\_E)

These functions output the logical NOT of input values.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <p>[Without EN/ENO]<br/>The function is described as an operator. \*1 DX cannot be used.

#### Processing details

#### ■Operation processing

- These functions perform a NOT operation (bit-by-bit) on the BOOL, WORD, or DWORD data type value input to (s), and output the operation result, in the same data type as (s), from (d).

**Ex.**

Data type: WORD

|     |     |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|-----|-----|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| (s) | 0   | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 |
|     | NOT |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| (d) | 1   | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |

- Input a BOOL, WORD, or DWORD data type value to (s).

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

#### Operation error

There is no operation error.

# 36 SELECTION FUNCTIONS

## 36.1 Selecting a Value

### SEL(\_E)

These functions output the selected input value.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                 |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=SEL(s1,s2,s3);<br/>[With EN/ENO]<br/>d:=SEL_E(EN,ENO,s1,s2,s3);</div> |
|  |  |                                                                                                    |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (G)   | Output condition (TRUE: s3 output, FALSE: s2 output)      | Input variable  | BOOL      |
| s2 (IN0) | Input                                                     | Input variable  | ANY       |
| s3 (IN1) |                                                           |                 |           |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | ANY       |

## Processing details

### ■ Operation processing

- These functions output either the (s2) or (s3) input value, in the same data type as (s2) or (s3), from (d) according to the value input to (s1).
- If the value input to (s1) is FALSE (=0), the (s2) input value is output from (d).
- If the value input to (s1) is TRUE (=1), the (s3) input value is output from (d).

#### Ex.

Data type of (s2) and (s3): INT (Argument names (s2) and (s3) correspond to the bit value (0 or 1) of (s1).)

- Input a BOOL data type value to (s1).
- Input a BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, TIME, structure, or array data type value to (s2) and (s3).

### ■ Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s2) and (s3) are of STRING data type

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (00H) in the label or device area (between the specified device number and the last device number) specified by (s2).<br>There is no NULL code (00H) in the label or device area (between the specified device number and the last device number) specified by (s3). |
| 3286H            | The entire string cannot be stored in the label or device area (between the specified device number and the last device number) specified by (d). (The number of required points is insufficient.)                                                                                         |

# 36.2     Selecting the Maximum/Minimum Value

## MAX(\_E), MIN(\_E)

- MAX(\_E): These functions output the maximum input value.
- MIN(\_E): These functions output the minimum input value.

| Ladder, FBD/LD*1                                                                                                  |                                                                                                                | ST                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <div>[Without EN/ENO]<br/></div> | <div>[With EN/ENO]<br/></div> | <div>[Without EN/ENO]<br/>d:=MAX(s1,s2);<br/>d:=MIN(s1,s2);<br/>[With EN/ENO]<br/>d:=MAX_E(EN,ENO,s1,s2);<br/>d:=MIN_E(EN,ENO,s1,s2);</div> |

\*1 The input variable s can be changed within the range from 2 to 28.

## Setting data

### ■Description, type, data type

| Argument               | Description                                               | Type            | Data type      |
|------------------------|-----------------------------------------------------------|-----------------|----------------|
| EN                     | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL           |
| s1 (IN1) to s28 (IN28) | Input                                                     | Input variable  | ANY_ELEMENTARY |
| ENO                    | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL           |
| d                      | Output                                                    | Output variable | ANY_ELEMENTARY |

## Processing details

### ■ Operation processing

#### • MAX(\_E)

These functions output the maximum value of the BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, or TIME data type values input to (s1) to (s28), in the same data type as (s), from (d).

**Ex.**

Data type: INT

#### • MIN(\_E)

These functions output the minimum value of the BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, or TIME data type values input to (s1) to (s28), in the same data type as (s), from (d).

**Ex.**

Data type: INT

• Input a BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, or TIME data type value to (s1) to (s28).

• Conditions for comparing the STRING data type values are as follows:

Match:

• All characters matched

Bigger string:

• The one having a character with a bigger code (when strings consist of different characters)  
• The one having a longer length (when strings are of different lengths)

Smaller string:

• The one having a character with a smaller code (when strings consist of different characters)  
• The one having a shorter length (when strings are of different lengths)

### ■ Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | From the device numbers specified by (s1) through (s28) onward, there is no NULL code (00H) in each setting area of the device/label memory.                                                   |
| 3285H            | The number of characters in the strings input to (s1) to (s28) exceeds 16383.                                                                                                                  |
| 3286H            | From the device numbers specified in (d) onward, the specified string cannot be fully stored in each setting area of the device/label memory. (The number of required points is insufficient.) |

# 36.3 Controlling the Upper/Lower Limit

## LIMIT(\_E)

These functions output an input value that has been controlled in terms of the upper and lower limits.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=LIMIT(s1,s2,s3);<br>[With EN/ENO]<br>d:=LIMIT_E(EN,ENO,s1,s2,s3); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                  | Type            | Data type      |
|----------|--------------------------------------------------------------|-----------------|----------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)    | Input variable  | BOOL           |
| s1(MN)*1 | Lower limit value (minimum output threshold value)           | Input variable  | ANY_ELEMENTARY |
| s2(IN)*1 | Input value to be controlled with the upper and lower limits | Input variable  | ANY_ELEMENTARY |
| s3(MX)*1 | Upper limit value (maximum output threshold value)           | Input variable  | ANY_ELEMENTARY |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)                | Output variable | BOOL           |
| d        | Output                                                       | Output variable | ANY_ELEMENTARY |

\*1 DX cannot be used.

## Processing details

### ■ Operation processing

- These functions output the value, in the same data type as (s1), (s2), or (s3), from (d) according to the BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, or TIME data type value input to (s1), (s2), and (s3).
- If the input values are  $(s2) > (s3)$ , the value input to (s3) is output from (d).
- If the input values are  $(s2) < (s1)$ , the value input to (s1) is output from (d).
- If the input values are  $(s1) \leq (s2) \leq (s3)$ , the value input to (s2) is output from (d).

**Ex.**

Data type: INT

- Input a BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, or TIME data type value to (s1), (s2), and (s3), provided that the input value is  $(s1) < (s3)$ .
- Conditions for comparing the STRING data type values are as follows:
  - Match:
    - All characters matched
  - Bigger string:
    - The one having a character with a bigger code (when strings consist of different characters)
    - The one having a longer length (when strings are of different lengths)
  - Smaller string:
    - The one having a character with a smaller code (when strings consist of different characters)
    - The one having a shorter length (when strings are of different lengths)

### ■ Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s1), (s2), and (s3) are of INT or WORD data type

| Error code (SD0) | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| 3285H            | The lower limit value specified by (s1) is greater than the upper limit value specified by (s2). |

- When (s1), (s2), and (s3) are of DINT, DWORD, or TIME data type

| Error code (SD0) | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| 3285H            | The lower limit value specified by (s1) is greater than the upper limit value specified by (s2). |

- When (s1), (s2), or (s3) are of BOOL data type

| Error code (SD0) | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| 3285H            | The lower limit value specified by (s1) is greater than the upper limit value specified by (s3). |

- When (s1), (s2), and (s3) are of REAL data type

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

\*1 The input variable s can be changed within the range from 2 to 28.

## Setting data

### ■Description, type, data type

| Argument               | Description                                               | Type            | Data type |
|------------------------|-----------------------------------------------------------|-----------------|-----------|
| EN                     | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| n(K)                   | Output value selection                                    | Input variable  | ANY_INT   |
| s1 (IN0) to s28 (IN27) | Input                                                     | Input variable  | ANY       |
| ENO                    | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d                      | Output                                                    | Output variable | ANY       |

## Processing details

### ■Operation processing

- These functions output one of the values input to (s1) to (s28), in the same data type as (s), from (d) according to the value input to (n).
- If the (n) input value is 0, the value input to (s1) is output from (d).
- If the (n) input value is (n)-1, the value input to (sn) is output from (d).

**Ex.**

Data type: INT

- If a value outside the range of the number of pins in (s) is input to (n), an undefined value is output from (d). (No operation error occurs. When MUX\_E is used, ENO outputs FALSE.)
- Input an INT, DINT, WORD, DWORD data type value to (n) within the range of 0 to 27, provided that it is within the range of the number of pins in (s).
- Input a BOOL, INT, DINT, WORD, DWORD, REAL, LREAL, STRING, TIME, structure, or array data type value to (s).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                    |

# 37 COMPARISON FUNCTIONS

37

## 37.1 Comparing Data

### GT(\_E), GE(\_E), EQ(\_E), LE(\_E), LT(\_E)

These functions output the comparison result of input values.

| Ladder, FBD/LD <sup>*1</sup> |               | ST <sup>*1</sup>                                                                                                                                                                                                                                         |
|------------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]             | [With EN/ENO] | [Without EN/ENO]<br>d:=GT(s1,s2);<br>d:=GE(s1,s2);<br>d:=EQ(s1,s2);<br>d:=LE(s1,s2);<br>d:=LT(s1,s2);<br>[With EN/ENO]<br>d:=GT_E(EN,ENO,s1,s2);<br>d:=GE_E(EN,ENO,s1,s2);<br>d:=EQ_E(EN,ENO,s1,s2);<br>d:=LE_E(EN,ENO,s1,s2);<br>d:=LT_E(EN,ENO,s1,s2); |

\*1 The input variable s can be changed within the range from 2 to 28.

### Setting data

#### ■Description, type, data type

| Argument                             | Description                                               | Type            | Data type      |
|--------------------------------------|-----------------------------------------------------------|-----------------|----------------|
| EN                                   | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL           |
| s1 (IN1) to s28 (IN28) <sup>*1</sup> | Input                                                     | Input variable  | ANY_ELEMENTARY |
| ENO                                  | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL           |
| d                                    | Output (TRUE, FALSE)                                      | Output variable | BOOL           |

\*1 DX cannot be used.

## Processing details

### ■Operation processing

- These functions perform comparison operation between the input values to (s), and output the operation result, in the BOOL data type, from (d).
- GT(\_E): Performs comparison of  $[(s1) > (s2)] \& [(s2) > (s3)] \& \dots \& [(s)_{(n-1)} > (s)_{(n)}]$ .
  - If all values satisfy  $(s)_{(n-1)} > (s)_{(n)}$ , TRUE is output.
  - If one of the values satisfies  $(s)_{(n-1)} \leq (s)_{(n)}$ , FALSE is output.
- GE(\_E): Performs comparison of  $[(s1) \geq (s2)] \& [(s2) \geq (s3)] \& \dots \& [(s)_{(n-1)} \geq (s)_{(n)}]$ .
  - If all values satisfy  $(s)_{(n-1)} \geq (s)_{(n)}$ , TRUE is output.
  - If one of the values satisfies  $(s)_{(n-1)} < (s)_{(n)}$ , FALSE is output.
- EQ(\_E): Performs comparison of  $[(s1) = (s2)] \& [(s2) = (s3)] \& \dots \& [(s)_{(n-1)} = (s)_{(n)}]$ .
  - If all values satisfy  $(s)_{(n-1)} = (s)_{(n)}$ , TRUE is output.
  - If one of the values satisfies  $(s)_{(n-1)} \neq (s)_{(n)}$ , FALSE is output.
- LE(\_E): Performs comparison of  $[(s1) \leq (s2)] \& [(s2) \leq (s3)] \& \dots \& [(s)_{(n-1)} \leq (s)_{(n)}]$ .
  - If all values satisfy  $(s)_{(n-1)} \leq (s)_{(n)}$ , TRUE is output.
  - If one of the values satisfies  $(s)_{(n-1)} > (s)_{(n)}$ , FALSE is output.
- LT(\_E): Performs comparison of  $[(s1) < (s2)] \& [(s2) < (s3)] \& \dots \& [(s)_{(n-1)} < (s)_{(n)}]$ .
  - If all values satisfy  $(s)_{(n-1)} < (s)_{(n)}$ , TRUE is output.
  - If one of the values satisfies  $(s)_{(n-1)} \geq (s)_{(n)}$ , FALSE is output.
- Input an INT, DINT, REAL, LREAL, BOOL, WORD, DWORD, TIME, or STRING type data value to (s). No WSTRING type Unicode string can be specified.
- Conditions for comparing the STRING data type values are as follows:
  - Match:
    - All characters matched
  - Bigger string:
    - The one having a character with a bigger code (when strings consist of different characters)
    - The one having a longer length (when strings are of different lengths)
  - Smaller string:
    - The one having a character with a smaller code (when strings consist of different characters)
    - The one having a shorter length (when strings are of different lengths)

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | From the device numbers specified by (s1) through (s28) onward, there is no NULL code (00H) in each setting area of the device/label memory.                                                   |
| 3285H            | The number of characters in the strings input to (s1) to (s28) exceeds 16383.                                                                                                                  |
| 3286H            | From the device numbers specified in (d) onward, the specified string cannot be fully stored in each setting area of the device/label memory. (The number of required points is insufficient.) |

## 37.2 Comparing Data

37

### NE(\_E)

These functions output the comparison result of input values.

| Ladder, FBD/LD   |               | ST                                                                           |
|------------------|---------------|------------------------------------------------------------------------------|
| [Without EN/ENO] | [With EN/ENO] | [Without EN/ENO]<br>d:=NE(s1,s2);<br>[With EN/ENO]<br>d:=NE_E(EN,ENO,s1,s2); |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type      |
|----------|-----------------------------------------------------------|-----------------|----------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL           |
| s1, s2   | Input                                                     | Input variable  | ANY_ELEMENTARY |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL           |
| d        | Output (TRUE, FALSE)                                      | Output variable | BOOL           |

### Processing details

#### ■Operation processing

- These functions perform comparison operation between the input values to (s), and output the operation result, in the BOOL data type, from (d).
- NE(\_E): Performs comparison of [(s1)≠(s2)].
  - If (s1)≠(s2), TRUE is output.
  - If (s1)=(s2), FALSE is output.
- Input an INT, DINT, REAL, LREAL, BOOL, WORD, DWORD, TIME, or STRING type data value to (s). No WSTRING type Unicode string can be specified.
- Conditions for comparing the STRING data type values are as follows:
  - Match:
    - All characters matched
  - Bigger string:
    - The one having a character with a bigger code (when strings consist of different characters)
    - The one having a longer length (when strings are of different lengths)
  - Smaller string:
    - The one having a character with a smaller code (when strings consist of different characters)
    - The one having a shorter length (when strings are of different lengths)

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | From the device numbers specified in (s) onward, there is no NULL code (00H) in each setting area of the device/label memory.                                                                  |
| 3285H            | The number of characters in the string input to (s) exceeds 16383.                                                                                                                             |
| 3286H            | From the device numbers specified in (d) onward, the specified string cannot be fully stored in each setting area of the device/label memory. (The number of required points is insufficient.) |

# 38 STRING FUNCTIONS

38

## 38.1 Detecting a String Length

### LEN(\_E)

These functions detect and output the length of the string input.

| Ladder, FBD/LD                                                                 | ST                                                                                                            |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <div> <div>[Without EN/ENO]</div> </div> <div> <div>[With EN/ENO]</div> </div> | <div>[Without EN/ENO]</div> <code>d:=LEN(s);</code> <div>[With EN/ENO]</div> <code>d:=LEN_E(EN,ENO,s);</code> |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type        |
|----------|-----------------------------------------------------------|-----------------|------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s (IN)   | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d        | Output                                                    | Output variable | INT              |

### Processing details

#### ■Operation processing

- These functions detect the length of the string input to (s), and output the length from (d).

- Input a STRING data type value to (s) within the range of 0 to 255 bytes.

#### ■Operation result

##### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

##### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE*1          | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | From the device numbers specified in (s) onward, there is no NULL code (00H) in each setting area of the device/label memory. |
| 3285H            | The number of characters in the string input to (s) exceeds 16383.                                                            |

## 38.2 Extracting String Data From the Left/Right

38

### LEFT(\_E), RIGHT(\_E)

- LEFT(\_E): These functions extract and output the specified number of characters, starting from the left end of the string input.
- RIGHT(\_E): These functions extract and output the specified number of characters, starting from the right end of the string input.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                        |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=LEFT(s,n);<br>d:=RIGHT(s,n);<br>[With EN/ENO]<br>d:=LEFT_E(EN,ENO,s,n);<br>d:=RIGHT_E(EN,ENO,s,n); |
|  |  |                                                                                                                           |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type        |
|----------|-----------------------------------------------------------|-----------------|------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s (IN)   | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| n (L)    | Number of characters to be extracted                      | Input variable  | INT              |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d        | Output                                                    | Output variable | ANYSTRING_SINGLE |

## Processing details

### ■Operation processing

#### • LEFT(\_E)

These functions extract the specified number of characters, starting from the left end of the string input to (s), and output the operation result from (d).

Specify the number of characters to be extracted in (n).

**Ex.**

When (n)=7

#### • RIGHT(\_E)

These functions extract the specified number of characters, starting from the right end of the string input to (s), and output the operation result from (d).

Specify the number of characters to be extracted in (n).

**Ex.**

When (n)=5

- Input a STRING data type value to (s) within the range of 0 to 255 bytes.
- Input an INT data type value to (n) within the range of 0 to 255, provided that it is within the number of characters in the string input to (s).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

38

| Error code (SD0) | Description                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | From the device numbers specified in (s) onward, there is no NULL code (00H) in each setting area of the device/label memory. |
| 3285H            | The number of characters in the string input to (s) exceeds 16383.                                                            |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type        |
|----------|-----------------------------------------------------------|-----------------|------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s (IN)   | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| n1 (L)   | Number of characters to be extracted                      | Input variable  | INT              |
| n2 (P)   | Extraction target character start position                | Input variable  | INT              |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d        | Output                                                    | Output variable | ANYSTRING_SINGLE |

## Processing details

### ■Operation processing

- These functions extract the specified number of characters, starting from the specified position of the string input to (s), and output the operation result from (d).
- Specify the number of characters to be extracted in (n1).
- Specify the start position of the string to be extracted in (n2).

**Ex.**

When (n1)=5, (n2)=5

- Input a STRING data type value to (s) within the range of 0 to 255 bytes.
- Input an INT data type value to (n1) within the range of 0 to 255, provided that it is within the number of characters in the string input to (s).
- Input an INT data type value to (n2) within the range of 1 to 255, provided that it is within the number of characters in the string input to (s).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | From the device numbers specified in (s) onward, there is no NULL code (00H) in each setting area of the device/label memory.                                                                                                                                                                                                                                                                                                                                                    |
| 3285H            | <p>The number of characters in the string input to (s) exceeds 16383.</p> <p>Out-of-range data is set to (n1) or (n2).</p> <ul style="list-style-type: none"> <li>• The value input to (n1) or (n2) is 0 or smaller.</li> <li>• The value input to (n2) is other than the valid values (-1, 0, 1 or bigger).</li> <li>• The value input to (n1) exceeds the number of characters in (s).</li> <li>• The sum of (n1) and (n2) exceeds the number of characters in (s).</li> </ul> |

# 38.4 Concatenating String Data

## CONCAT(\_E)

These functions concatenate strings, and output the operation result.

| Ladder, FBD/LD <sup>*1</sup>                                                      |                                                                                   | ST <sup>*1</sup>                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=CONCAT(s1,s2);<br>[With EN/ENO]<br>d:=CONCAT_E(EN,ENO,s1,s2); |
|  |  |                                                                                      |

<sup>\*1</sup> The input variable s can be changed within the range from 2 to 28.

### Setting data

#### ■Description, type, data type

| Argument               | Description                                               | Type            | Data type        |
|------------------------|-----------------------------------------------------------|-----------------|------------------|
| EN                     | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s1 (IN1) to s28 (IN28) | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| ENO                    | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d                      | Output                                                    | Output variable | ANYSTRING_SINGLE |

### Processing details

#### ■Operation processing

- These functions concatenate the strings input to (s2) to (s28) to the end of the string input to (s1), and output the operation result from (d).
- The (s2) to (s28) strings are concatenated successively, ignoring 00H, which indicates the end of the (s1) string.
- If the string after concatenation exceeds 255 bytes, the substring up to the 255th byte will be output.

| (s1)<br><u>ABCDE</u> |            |            | + | (s2)<br><u>123456</u> |            |            | ⇒ | (d)<br><u>ABCDE123456</u> |            |            |

| ENO                | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d                  | Output                                                    | Output variable | ANYSTRING_SINGLE |

## Processing details

### ■Operation processing

- These functions insert the string input to (s2) into the insertion start position, i.e. the 'n'th character position from the beginning of the string input to (s1), and output the operation result from (d).
- After the (s2) string is inserted into the (s1) string, 00H, which indicates the end of the (s2) string, is ignored.
- If the string after insertion exceeds 255 bytes, the substring up to the 255th byte will be output.

**Ex.**

When (n)=4

- Input a STRING data type value to (s1) and (s2) within the range of 0 to 255 bytes.
- Input an INT data type value to (n) within the range of 1 to 255, provided that it is within the number of characters in the string input to (s1).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type        |
|----------|-----------------------------------------------------------|-----------------|------------------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s (IN)   | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| n1 (L)   | Number of characters to be deleted                        | Input variable  | INT              |
| n2 (P)   | Deletion target character start position                  | Input variable  | INT              |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d        | Output                                                    | Output variable | ANYSTRING_SINGLE |

## Processing details

### ■Operation processing

- These functions delete the specified number of characters, starting from the desired position of the string input to (s), and output the remaining substring from (d).
- Specify the number of characters to be deleted in (n1).
- Specify the start position of the string to be deleted in (n2).

**Ex.**

When (n1)=5, (n2)=5

- Input a STRING data type value to (s) within the range of 0 to 255 bytes.
- Input an INT data type value to (n1) within the range of 0 to 255, provided that it is within the number of characters in the string input to (s).
- Input an INT data type value to (n2) within the range of 1 to 255, provided that it is within the number of characters in the string input to (s).

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | There is no NULL code (00H) in the label or device area (between the specified device number and the last device number) specified by (s).                                |
| 3285H            | The number of characters in the string input to (s) exceeds 255.                                                                                                          |
|                  | The value input to (n1) is out of the range, 0 to 255.                                                                                                                    |
|                  | The value input to (n2) is out of the range, 1 to 255.                                                                                                                    |
|                  | The value input to (n1) exceeds the number of characters in (s).                                                                                                          |
|                  | The value input to (n2) exceeds the number of characters in (s).                                                                                                          |
| 3286H            | The entire string after delete processing cannot be stored in the label or device area (between the specified device number and the last device number) specified by (d). |

# 38.7 Replacing String Data

## REPLACE(\_E)

These functions replace the specified range in a string, and output the operation result.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                               |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=REPLACE(s1,s2,n1,n2);<br/>[With EN/ENO]<br/>d:=REPLACE_E(EN,ENO,s1,s2,n1,n2);</div> |
|  |  |                                                                                                                  |

### Setting data

#### ■Description, type, data type

| Argument           | Description                                               | Type            | Data type        |
|--------------------|-----------------------------------------------------------|-----------------|------------------|
| EN                 | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s1 (IN1), s2 (IN2) | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| n1 (L)             | Number of characters to be replaced                       | Input variable  | INT              |
| n2 (P)             | Replacement target character start position               | Input variable  | INT              |
| ENO                | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d                  | Output                                                    | Output variable | ANYSTRING_SINGLE |

## Processing details

### Operation processing

- These functions replace the specified number of characters starting from the desired position of the string input to (s1) with the string input to (s2), and output the operation result from (d).
- Specify the number of characters to be replaced in (n1).
- Specify the start position of the string to be replaced in (n2).

**Ex.**

When (n1)=5, (n2)=5

- Input a STRING data type value to (s1) and (s2) within the range of 0 to 255 bytes.
- Input an INT data type value to (n1) within the range of 0 to 255, provided that it is within the number of characters in the string input to (s1).
- Input an INT data type value to (n2) within the range of 1 to 255, provided that it is within the number of characters in the string input to (s1).

### Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# 38.8 Searching String Data

## FIND(\_E)

These functions search a string, and output the operation result.

| Ladder, FBD/LD                                                                                        |                                                                                                    | ST                                                                               |
|-------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| [Without EN/ENO]<br> | [With EN/ENO]<br> | [Without EN/ENO]<br>d:=FIND(s1,s2);<br>[With EN/ENO]<br>d:=FIND_E(EN,ENO,s1,s2); |

### Setting data

#### ■Description, type, data type

| Argument           | Description                                               | Type            | Data type        |
|--------------------|-----------------------------------------------------------|-----------------|------------------|
| EN                 | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL             |
| s1 (IN1), s2 (IN2) | Input                                                     | Input variable  | ANYSTRING_SINGLE |
| ENO                | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL             |
| d                  | Output                                                    | Output variable | INT              |

## Processing details

### ■Operation processing

- These functions search the string input to (s2) from the beginning of the string input to (s1), and output the search result from (d).
- The start character position of the first string found is output as the search result.
- If the (s2) string is not found in the (s1) string, 0 will be output.

- Input a STRING data type value to (s1) and (s2) within the range of 0 to 255 bytes.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

\*1 If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0) | Description                                                                                                                    |

# 39 TIME DATA TYPE FUNCTIONS

## 39.1 Addition

### ADD\_TIME(\_E)

These functions output the sum ((s1)+(s2)) of the TIME data type input values.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=ADD_TIME(s1,s2);<br/>[With EN/ENO]<br/>d:=ADD_TIME_E(EN,ENO,s1,s2);</div> |
|  |  |                                                                                                        |

### Setting data

#### ■Description, type, data type

| Argument           | Description                                               | Type            | Data type |
|--------------------|-----------------------------------------------------------|-----------------|-----------|
| EN                 | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1), s2 (IN2) | Input                                                     | Input variable  | TIME      |
| ENO                | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d                  | Output                                                    | Output variable | TIME      |

## Processing details

### ■Operation processing

- These functions perform addition of the TIME data type values input to (s1) and (s2) ((s1)+(s2)), and output the operation result, in the TIME data type, from (d).

**Ex.**

When (s1)=T#1d2h33m44s55ms (1 day, 2 hours, 33 minutes, 44 seconds, 55 milliseconds) and (s2)=T#2ms (2 milliseconds)

- Input a TIME data type value to (s1) and (s2).
- Even if an underflow or overflow occurs in the operation result, no operation error is issued. The following is output to (d).  
When ADD\_TIME\_E is used, ENO outputs TRUE.

**Ex.**

Overflow

A negative time value results because the most significant bit is 1.

**Ex.**

Underflow

A positive time value results because the most significant bit is 0.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

# 39.2 Subtraction

## SUB\_TIME(\_E)

These functions output the difference ((s1)-(s2)) between the TIME data type input values.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                     |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>d:=SUB_TIME(s1,s2);<br/>[With EN/ENO]<br/>d:=SUB_TIME_E(EN,ENO,s1,s2);</div> |
|  |  |                                                                                                        |

### Setting data

#### ■Description, type, data type

| Argument           | Description                                               | Type            | Data type |
|--------------------|-----------------------------------------------------------|-----------------|-----------|
| EN                 | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1), s2 (IN2) | Input                                                     | Input variable  | TIME      |
| ENO                | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d                  | Output                                                    | Output variable | TIME      |

## Processing details

### ■Operation processing

- These functions perform subtraction between the TIME data type values input to (s1) and (s2) ((s1)-(s2)), and output the operation result, in the TIME data type, from (d).

**Ex.**

When (s1)=T#1d2h33m44s55ms (1 day, 2 hours, 33 minutes, 44 seconds, 55 milliseconds) and (s2)=T#2ms (2 milliseconds)

- Input a TIME data type value to (s1) and (s2).
- Even if an underflow or overflow occurs in the operation result, no operation error is issued. The following is output to (d).  
When SUB\_TIME\_E is used, ENO outputs TRUE.

**Ex.**

Overflow

A negative time value results because the most significant bit is 1.

**Ex.**

Underflow

A positive time value results because the most significant bit is 0.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

There is no operation error.

# 39.3 Multiplication

## MUL\_TIME(\_E)

These functions output the product ((s1)×(s2)) of the TIME data type input values.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                       |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>d:=MUL_TIME(s1,s2);<br>[With EN/ENO]<br>d:=MUL_TIME_E(EN,ENO,s1,s2); |
|  |  |                                                                                          |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1) | Input                                                     | Input variable  | TIME      |
| s2 (IN2) | Input                                                     | Input variable  | ANY_NUM   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | TIME      |

## Processing details

### ■Operation processing

- These functions perform multiplication between the TIME data type values input to (s1) and (s2) ((s1)×(s2)), and output the operation result, in the TIME data type, from (d).

**Ex.**

When (s1)=T#1d2h33m44s55ms (1 day, 2 hours, 33 minutes, 44 seconds, 55 milliseconds) and (s2)=2

- Input a TIME data type value to (s1).
- Input an INT, DINT, REAL, or LREAL data type value to (s2).
- Even if an underflow or overflow occurs in the operation result, no operation error is issued. The following is output to (d).  
 When MUL\_TIME\_E is used, ENO outputs TRUE. (In this case, the output value is of TIME data type with the upper 32 bits deleted although the operation result is 64-bit data.)

**Ex.**

Overflow

A negative time value results because the most significant bit is 1.

**Ex.**

Underflow

A positive time value results because the most significant bit is 0.

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

- When (s2) is of LREAL data type

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                         |

|  |  |                                                                                                        |

### Setting data

#### ■Description, type, data type

| Argument | Description                                               | Type            | Data type |
|----------|-----------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed) | Input variable  | BOOL      |
| s1 (IN1) | Input                                                     | Input variable  | TIME      |
| s2 (IN2) | Input                                                     | Input variable  | ANY_NUM   |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal)             | Output variable | BOOL      |
| d        | Output                                                    | Output variable | TIME      |

## Processing details

### ■Operation processing

- These functions perform division between the TIME data type values input to (s1) and (s2) ((s1)÷(s2)), and output the operation result, in the TIME data type, from (d). The remainder is rounded down.

**Ex.**

When (s1)=T#1d2h33m44s55ms (1 day, 2 hours, 33 minutes, 44 seconds, 55 milliseconds) and (s2)=2

- Input a TIME data type value to (s1).
- Input an INT, DINT, REAL, or LREAL data type value to (s2). (Note that the value input to (s2) shall be other than 0.)

### ■Operation result

#### 1. Function without EN/ENO

The operation processing is performed. The operation result is output from (d).

#### 2. Function with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result    |                               |
|----------------------|---------------------|-------------------------------|
| EN                   | ENO                 | (d)                           |
| TRUE (executed)      | TRUE                | Operation result output value |
| FALSE (not executed) | FALSE <sup>*1</sup> | Undefined value               |

<sup>\*1</sup> If the value FALSE is output from ENO, the output data from (d) will be undefined. Create a program so that the undefined value will not be used in operations.

## Operation error

| Error code (SD0)                  | Description                                                                                                                                                                                                                                            |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3280H                             | The value input to (s2) is 0. (The value is divided by zero.)                                                                                                                                                                                          |

# 40 BISTABLE FUNCTION BLOCKS

## 40.1 Bistable Function Block (Set-dominant)

### SR(\_E)

These function blocks discriminate between two input values, and output 1 (TRUE) or 0 (FALSE).

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                                          |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>Instance name(S1:=s1,R:=s2,Q1:=d);<br/>[With EN/ENO]<br/>Instance name(EN:=en,ENO:=eno,S1:=s1,R:=s2,Q1:=d);</div> |
|  |  |                                                                                                                                             |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s1 (S1)  | Set command                                                     | Input variable  | BOOL      |
| s2 (R)   | Reset command                                                   | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d (Q1)   | Output                                                          | Output variable | BOOL      |

## Processing details

### ■ Operation processing

- When (s1) turns on, (d) is set. Turning on (s2) while (s1) is off resets (d).
- Even when (s2) turns on while (s1) is on, (d) is not reset.

### ■ Operation result

#### 1. Function block without EN/ENO

The operation processing is performed. The operation result is output from (d).

- Timing chart

- (1) When (s1) turns on, (d) turns on.  
 (2) When (s2) turns on while (s1) is off, (d) turns off.

#### 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE            | Previous output value         |

- Timing chart

- (1) When (s1) turns on while EN is on, (d) turns on.  
 (2) When (s2) turns on while EN is on and (s1) is off, (d) turns off.

## Operation error

There is no operation error.

# 40.2 Bistable Function Block (Reset-dominant)

## RS(\_E)

These function blocks discriminate between two input values, and output 1 (TRUE) or 0 (FALSE).

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                            |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>Instance name(S:=s1,R1:=s2,Q1:=d);<br>[With EN/ENO]<br>Instance name(EN:=en,ENO:=eno,S:=s1,R1:=s2,Q1:=d); |
|  |  |                                                                                                                               |

## Setting data

### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s1 (S)   | Set command                                                     | Input variable  | BOOL      |
| s2 (R1)  | Reset command                                                   | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d (Q1)   | Output                                                          | Output variable | BOOL      |

## Processing details

### ■ Operation processing

- When (s1) turns on, (d) is set. When (s2) turns on, (d) is reset.
- Even when (s1) turns on while (s2) is on, (d) is not set.

### ■ Operation result

#### 1. Function block without EN/ENO

The operation processing is performed. The operation result is output from (d).

- Timing chart

(1) When (s2) turns off while (s1) is on, (d) turns on.

(2) When (s2) turns on, (d) turns off.

#### 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE            | Previous output value         |

- Timing chart

(1) When (s2) turns off while EN is on and (s1) is on, (d) turns on.

(2) When (s2) turns on while EN is on, (d) turns off.

## Operation error

There is no operation error.

# 41 EDGE DETECTION FUNCTION BLOCKS

## 41.1 Detecting a Rising Edge

### R\_TRIG(\_E)

These function blocks detect a signal rising edge, and outputs the pulse signal.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                            |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>Instance name(CLK:=s,Q:=d);<br/>[With EN/ENO]<br/>Instance name(EN:=en,ENO:=eno,CLK:=s,Q:=d);</div> |
|  |  |                                                                                                                               |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (CLK)  | Rising edge detection input                                     | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d (Q)    | Output                                                          | Output variable | BOOL      |

## Processing details

### ■ Operation processing

When (s) turns on, (d) turns on only for one scan.

### ■ Operation result

#### 1. Function block without EN/ENO

The operation processing is performed. The operation result is output from (d).

- Timing chart

(1) (d) turns on at the rising edge of (s).

(2) (d) turns off in the next scan.

#### 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE            | Previous output value         |

- Timing chart

(1) (d) turns on at the rising edge of (s) while EN is on.

(2) (d) turns off in the next scan.

(3) If EN is off, (d) holds the output value of the last scan.

## Operation error

There is no operation error.

# 41.2 Detecting a Falling Edge

## F\_TRIG(\_E)

These function blocks detect a signal falling edge, and outputs the pulse signal.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                               |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | [Without EN/ENO]<br>Instance name(CLK:=s,Q:=d);<br>[With EN/ENO]<br>Instance name(EN:= en,ENO:=eno,CLK:=s,Q:=d); |
|  |  |                                                                                                                  |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (CLK)  | Falling edge detection input                                    | Input variable  | BOOL      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d (Q)    | Output                                                          | Output variable | BOOL      |

## Processing details

### ■ Operation processing

When (s) turns off, (d) turns on only for one scan.

### ■ Operation result

#### 1. Function block without EN/ENO

The operation processing is performed. The operation result is output from (d).

- Timing chart

(1) (d) turns on at the falling edge of (s).

(2) (d) turns off in the next scan.

#### 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d)                           |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE            | Previous output value         |

- Timing chart

(1) (d) turns on at the falling edge of (s) while EN is on.

(2) (d) turns off in the next scan.

(3) If EN is off, (d) holds the output value of the last scan.

## Operation error

There is no operation error.

# 42 COUNTER/TIMER FUNCTION BLOCKS

## 42.1 Up Counter

### CTU(\_E)

These function blocks count up the number of rising edges of a signal.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                                                                    |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [Without EN/ENO]                                                                  | [With EN/ENO]                                                                     | <div>[Without EN/ENO]<br/>Instance name(CU:=s1,R:=s2,PV:=n,Q:=d1,CV:=d2);<br/>[With EN/ENO]<br/>Instance name(EN:=en,ENO:=eno,CU:=s1,R:=s2,PV:=n,Q:=d1,CV:=d2);</div> |
|  |  |                                                                                                                                                                       |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s1 (CU)  | Count signal input                                              | Input variable  | BOOL      |
| s2 (R)   | Count value reset                                               | Input variable  | BOOL      |
| n (PV)   | Maximum count value                                             | Input variable  | INT       |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d1 (Q)   | End of count                                                    | Output variable | BOOL      |
| d2 (CV)  | Count value                                                     | Output variable | INT       |

### Processing details

#### ■Operation processing

##### 1. Counting up

- When (s1) changes from off to on, the value in (d2) is counted up by one.
- When (d2) reaches the (n) value, (d1) turns on and the counting stops.
- Set the maximum counter value to (n). When (s2) turns on, (d1) turns off and (d2) is set to 0.

##### 2. Maximum count value

The valid setting range of (n) is 0 to 32767.

## ■Operation result

## 1. Function block without EN/ENO

The operation processing is performed. The operation result is output from (d1) and (d2).

- Timing chart

When  $(n)=3$

- (1) When (s1) turns on, the value in (d2) is counted up.
- (2) When (s2) turns on, the value in (d2) is initialized.

## 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d1), (d2)                    |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE            | Previous output value         |

- Timing chart

When  $(n)=3$

- (1) When (s1) turns on while EN is on, the value in (d2) is counted up.
- (2) When (s2) turns on while EN is on, the value in (d2) is initialized.

## Operation error

There is no operation error.

## 42.2 Down Counter

### CTD(\_E)

These function blocks count down the number of rising edges of a signal.

| Ladder, FBD/LD                                                                    |                                                                                   | ST                                                                                                                                                        |

## Processing details

### ■ Operation processing

In (n), set the maximum count value for up count and the start count value for down count. The valid range of (n) is 0 to 32767.

#### 1. Counting up

- When (s1) changes from off to on, the value in (d3) is counted up by one.
- When (d3) reaches the (n) value, (d1) turns on and the counting stops.
- When (s3) turns on, (d1) turns off and (d3) is set to 0.

#### 2. Counting down

- When (s2) changes from off to on, the value in (d3) is counted down by one.
- When (d3) is 0, (d2) turns on and the counting stops.
- When (s4) turns on, (d2) turns off and (n) is set to (d3).

#### 3. Others

- When (s1) and (s2) change from off to on simultaneously, the value in (d3) is counted up by one with priority given to (s1).
- When (s3) and (s4) turn on simultaneously, (d3) is set to 0 with priority given to (s3).

### ■ Operation result

#### 1. Function block without EN/ENO

The operation processing is performed. The operation result is output from (d1), (d2), and (d3).

- Timing chart

When (n)=3

- (1) When (s1) turns on, the value in (d3) is counted up.
- (2) When (s3) turns on, the value in (d3) is initialized.
- (3) When (s2) turns on, the value in (d3) is counted down.
- (4) When (s4) turns on, the value in (d3) is initialized.

## 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result |                               |
|----------------------|------------------|-------------------------------|
| EN                   | ENO              | (d1), (d2), (d3)              |
| TRUE (executed)      | TRUE             | Operation result output value |
| FALSE (not executed) | FALSE            | Previous output value         |

### • Timing chart

When (n)=3

- (1) When (s1) turns on while EN is on, the value in (d3) is counted up.
- (2) When (s3) turns on while EN is on, the value in (d3) is initialized.
- (3) When (s2) turns on while EN is on, the value in (d3) is counted down.
- (4) When (s4) turns on while EN is on, the value in (d3) is initialized.

### Operation error

There is no operation error.

# 42.4 Counter Function Block

## COUNTER\_FB\_M

This function block starts counting up when the execution condition is satisfied.

| Ladder, FBD/LD                                                                    | ST                                                                      |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------|
|  | Instance name(Coil:=s1,Preset:=s2,ValueIn:=s3,ValueOut:=d1,Status:=d2); |

### Setting data

| d2 (Status)   | Output                                                    | Output variable | BOOL      |

## Processing details

### ■ Operation processing

- The number of rising edges (status changes (off to on)) of (s1) is counted. Counting is not performed while (s1) remains on. The counting starts from the (s3) value. When it reached the (s2) value, (d2) turns on. The current value is stored in (d1).
- The valid setting range of (s2) is 0 to 32767.
- The valid setting range of (s3) is -32768 to 32767. Note that if a negative value is specified, 0 will be used as the initial value.
- To reset the current value (d1), reset (s1) of FB directly.

### Processing details

#### ■Operation processing

##### 1. Output

- When (s) turns on, (d1) turns on for the period of time set by (n). The time elapsed after (d1) turns on is set to (d2).
- Use the long timer to count the elapsed time.

##### 2. End of output

- Once the elapsed time reaches the setting time, (d1) turns off.
- If (s) is off after (d1) turns off, the elapsed time is reset.
- Even when (s) turns off while (d1) is on, (d1) does not turn off.

##### 3. Output time setting

The valid setting range of (n) is T#1ms to T#2147483ms. Note that the valid setting range will be as follows by changing the timer limit setting using the engineering tool.

| Minimum value                                                                                                                                                               | Maximum value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Identical to the long timer setting value [ms] in the timer limit setting.<br>Note that if the long timer setting value is smaller than 1ms, the minimum value will be 1ms. | The time satisfying the following condition is used.<br>Note that the maximum value is a value that can be included within the range of time type because the output time setting value is of time type (32-bit value). <ul style="list-style-type: none"> <li>Output time setting value [ms] ≤ 2147483647 [ms] × Long timer setting value in the timer limit setting [ms]</li> </ul> [Example] <ul style="list-style-type: none"> <li>If the long timer setting value is 0.001ms: T#1ms to T#2147483ms</li> <li>If the long timer setting value is 1000ms: T#1000ms to T#2147483000ms</li> </ul> |

The value at the rising edge (off to on) of (d1) is used for the setting value of (n). When the (n) value is changed when (d1) is on, the new value will be enabled at the next output start timing.

## ■Operation result

### 1. Function block without EN/ENO

The operation result will be as follows.

| Operation result   | (d1), (d2)                    |
|--------------------|-------------------------------|
| No operation error | Operation result output value |
| Operation error    | Undefined value               |

#### • Timing chart

When  $n=T\#5s$  (5s)

(1) When (s) turns on, (d1) turns on. When (s) turns on, (d2) starts measuring time.

(2) When the time measured in (d2) reaches the time set in (n), (d1) turns off.

(3) When both (s) and (d1) are off, the value in (d2) is initialized.

### 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result          |                               |
|----------------------|---------------------------|-------------------------------|
| EN                   | ENO                       | (d1), (d2)                    |
| TRUE (executed)      | TRUE (no operation error) | Operation result output value |
|                      | FALSE (operation error)   | Undefined value               |
| FALSE (not executed) | FALSE                     | Previous output value         |

#### • Timing chart

When  $n=T\#5s$  (5s)

(1) When (s) turns on while EN is on, (d1) turns on. When (s) turns on while EN is on, (d2) starts measuring time.

(2) While EN is on, the time value is incremented by 1.

(3) When the time measured in (d2) reaches the time set in (n), (d1) turns off.

(4) When EN is on and both (s) and (d1) are off, the value in (d2) is initialized.

## Operation error

| Error code (SD0) | Description                                            |
|------------------|--------------------------------------------------------|
| 3281H            | The output time setting value exceeds the valid range. |

### Setting data

#### ■Description, type, data type

| Argument | Description                                                     | Type            | Data type |
|----------|-----------------------------------------------------------------|-----------------|-----------|
| EN       | Execution condition (TRUE: Executed, FALSE: Not executed)       | Input variable  | BOOL      |
| s (IN)   | Time measurement                                                | Input variable  | BOOL      |
| n (PT)   | Delay time setting value                                        | Input variable  | TIME      |
| ENO      | Output status (TRUE: Normal, FALSE: Abnormal or operation stop) | Output variable | BOOL      |
| d1 (Q)   | Output                                                          | Output variable | BOOL      |
| d2 (ET)  | Elapsed time                                                    | Output variable | TIME      |

### Processing details

#### ■Operation processing

##### 1. Output

- When (s) turns on, (d1) turns on after the time that was set by (n). The delay time elapsed after (d1) turns on is set to (d2).
- When (s) turns off, (d1) turns off and the delay elapsed time is also reset.
- Use the long timer to count the elapsed time.

##### 2. Delay time setting

The valid setting range of (n) is T#1ms to T#2147483ms. Note that the valid setting range will be as follows by changing the timer limit setting using the engineering tool.

| Minimum value                                                                                                                                                               | Maximum value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Identical to the long timer setting value [ms] in the timer limit setting.<br>Note that if the long timer setting value is smaller than 1ms, the minimum value will be 1ms. | The time satisfying the following condition is used.<br>Note that the maximum value is a value that can be included within the range of time type because the delay time setting value is of time type (32-bit value). <ul style="list-style-type: none"> <li>• Delay time setting value [ms] <math>\leq</math> 2147483647 [ms] <math>\times</math> Long timer setting value of in the timer limit setting [ms]</li> </ul> [Example] <ul style="list-style-type: none"> <li>• If the long timer setting value is 0.001ms: T#1ms to T#2147483ms</li> <li>• If the long timer setting value is 1000ms: T#1000ms to T#2147483000ms</li> </ul> |

The value at the rising edge (off to on) of (d) is used for the setting value of (n). When the (n) value is changed while (s) is on, the new value will be enabled at the next rising edge of (s).

## ■ Operation result

### 1. Function block without EN/ENO

The operation result will be as follows.

| Operation result   | (d1), (d2)                    |
|--------------------|-------------------------------|
| No operation error | Operation result output value |
| Operation error    | Undefined value               |

#### • Timing chart

When  $n=T\#5s$  (5s)

- (1) When (s) turns on, (d2) starts measuring time.  
 (2) When the time measured in (d2) reaches the time set in (n), (d1) turns on.  
 (3) When both (s) and (d1) turn off, the value in (d2) is initialized.

### 2. Function block with EN/ENO

The execution conditions and operation results will be as follows.

| Execution condition  | Operation result          |                               |
|----------------------|---------------------------|-------------------------------|
| EN                   | ENO                       | (d1), (d2)                    |
| TRUE (executed)      | TRUE (no operation error) | Operation result output value |
|                      | FALSE (operation error)   | Previous output value         |
| FALSE (not executed) | FALSE                     | Previous output value         |

#### • Timing chart

When  $n=T\#5s$  (5s)

- (1) When (s) turns on while EN is on, (d2) starts measuring time.  
 (2) When the time measured in (d2) reaches the time set in (n), (d1) turns on.  
 (3) When both (s) and (d1) turn off while EN is on, the value in (d2) is initialized.

## Operation error

| Error code (SD0) | Description                                            |
|------------------|--------------------------------------------------------|
| 3281H            | The output time setting value exceeds the valid range. |

## 42.7 Off Delay Timer

### TOF(\_E)

These function blocks turn off a signal after the specified period of time.

| Ladder, FBD/LD   |               | ST                                                                                                                                        |

### Processing details

#### ■TIMER\_10\_FB\_M

- When (s1) turns on, measurement of the current value starts. The measurement starts from (s3)×10ms. When the value reaches (s2)×10ms, (d2) turns on. The measured current value is output to (d1).
- When (s1) turns off, the current value (d1) becomes 0, and (d2) also turns off.
- If the unit of measurement of the high-speed timer (in the timer limit setting) is changed from the default value using the engineering tool, a warning will be issued during conversion of modified or newly added programs or all programs in a project.
- The valid setting range of (s2) is 0 to 32767.
- The valid setting range of (s3) is -32768 to 32767. Note that if a negative value is specified, 0 will be used as the initial value.

Ex.

[Ladder example]

[Timing chart]

## ■TIMER\_100\_FB\_M

- When (s1) turns on, measurement of the current value starts. The measurement starts from (s3)×100ms. When the value reaches (s2)×100ms, (d2) turns on. The measured current value is output to (d1).
- When (s1) turns off, the current value (d1) becomes 0, and (d2) also turns off.
- If the unit of measurement of the low-speed timer (in the timer limit setting) is changed from the default value using the engineering tool, a warning will be issued during conversion of modified or newly added programs or all programs in a project.
- The valid setting range of (s2) is 0 to 32767.
- The valid setting range of (s3) is -32768 to 32767. Note that if a negative value is specified, 0 will be used as the initial value.

**Ex.**

[Ladder example]

[Timing chart]

## ■TIMER\_HIGH\_FB\_M

- This is a high-speed timer whose unit of measurement is 0.1 to 100ms. When (s1) turns on, measurement of the current value starts. The measurement starts from (s3)×0.1 to 100ms (variable; set in parameter). When the value reaches (s2)×0.1 to 100ms, (d2) turns on. The measured current value is output to (d1).
- When (s1) turns off, the current value (d1) becomes 0, and (d2) also turns off.
- The unit of measurement of the high-speed timer is 10ms by default. The unit can be changed in the range from 0.01 to 100ms.
- The valid setting range of (s2) is 0 to 32767.
- The valid setting range of (s3) is -32768 to 32767. Note that if a negative value is specified, 0 will be used as the initial value.

**Ex.**

[Ladder example]

[Timing chart]

## ■TIMER\_LOW\_FB\_M

- This is a low-speed timer whose unit of measurement is 1 to 1000ms. When (s1) turns on, measurement of the current value starts. The measurement starts from (s3)×1 to 1000ms (variable; set in parameter). When the value reaches (s2)×1 to 1000ms, (d2) turns on. The measured current value is output to (d1).
- When (s1) turns off, the current value (d1) becomes 0, and (d2) also turns off.
- The unit of measurement of the low-speed timer is 100ms by default. The unit can be changed in the range from 1 to 1000ms (in increments of 1ms).
- The valid setting range of (s2) is 0 to 32767.
- The valid setting range of (s3) is -32768 to 32767. Note that if a negative value is specified, 0 will be used as the initial value.

**Ex.**

[Ladder example]

[Timing chart]

## ■TIMER\_CONT\_FB\_M/TIMER\_CONTHFB\_M

- This is a retentive timer that measures the on time of a variable. When (s1) turns on, measurement of the current value starts. There are two retentive timers: low-speed (TIMER\_CONT\_FB\_M) and high-speed (TIMER\_CONTHFB\_M) retentive timers.
- The measurement starts from (s3)×1 to 1000ms (0.1 to 100ms for the high-speed retentive timer) (variable; set in parameter). When the value reaches (s2)×1 to 1000ms (0.1 to 100ms for the high-speed retentive timer), (d2) turns on. The measured current value is output to (d1).
- Even when (s1) is off, the on/off states of (d1) and (d2) are held. When (s1) turns on again, the measurement resumes with the measured value that has been held.
- The unit of measurement (time limit) for the retentive timers is common to both the low-speed timer (TIMER\_LOW\_FB\_M) and high-speed timer (TIMER\_HIGH\_FB\_M).
  - Low-speed retentive timer: Low-speed timer
  - High-speed retentive timer: High-speed timer
- The valid setting range of (s2) is 0 to 32767.
- The valid setting range of (s3) is -32768 to 32767. Note that if a negative value is specified, 0 will be used as the initial value.
- To reset (d1) of a retentive timer, reset (s1) of FB directly.

# 43 MOTION CONTROL FB OVERVIEW

This chapter describes how to use motion control FBs and the specifications.

The motion control FB includes FBs established by PLCopen®. The basic specifications of I/O signals follow the PLCopen® motion control FBs.

For the common specifications of the function block, refer to the following.

☞ Page 66 Function Blocks (FB)

## 43.1 Motion Control FBs

This section describes the Motion control FBs.

### How to use Motion control FBs

The procedure for using Motion control FBs is described below.

1. Create the motion control FB instance (global label or local label) using the engineering tool.
2. Create a program which sets the I/O argument for the Motion control FB instance.
3. The control will be executed when Execution command (Execute) or Enable (Enable) of the Motion control FB is set to TRUE.

#### Point

- When one Motion control FB instance is being executed (including during buffering), the instance cannot be executed on multiple axes by changing the axis input (AXIS\_REF input or AXES\_GROUP\_REF input). The axis input of the Motion control FB can only be changed when an instance is not being executed. When the axis input is changed while an instance is being executed, a warning will occur and the change will be ignored. Therefore, ensure that the number of Motion control FB instances created is equal to the number of axes being controlled at the same time.
- Do not allow one motion control FB instance to be called from multiple programs (programs to be executed in parallel, including interrupt programs) at the same time. Operation when an instance is called at the same time cannot be guaranteed.

### Operation of motion control FBs for each system status

Motion control FBs can only be executed during RUN.

○: Available, ×: Not available

| System status  | Operation availability |
|----------------|------------------------|
| STOP           | ×                      |
| RUN            | ○                      |
| Moderate error | ×                      |
| Major error    | ×                      |

## Motion control FB types

Motion control FBs are classified according the operation details and the execution method.

### Administrative FBs/Motion related FBs/Standard FBs

Motion control FBs are classified into the following types according to the operation details.

| Type              | Operation details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Administrative FB | <ul style="list-style-type: none"> <li>• A motion control FB that takes an axis or an axes group for the argument and does not change the axis status or the axes group status by execution. (There are some exceptions.)</li> <li>• In most cases, an administrative FB can execute multiple instances to an axis or an axes group at the same time.</li> <li>• When multiple instances are executed for an axis or an axes group at the same time, control is preferentially performed from the one whose priority by which to execute the motion control FB is high.</li> </ul>                                                                                                                                                                                                                                              |
| Motion related FB | <ul style="list-style-type: none"> <li>• A motion control FB that takes an axis or an axes group for the argument and changes the axis status or the axes group status by execution.</li> <li>• In most cases, a motion FB can be executed to only one axis or axes group. However, some motion control FBs can be executed at the same time.</li> <li>• In most cases, the axis status or the axes group status will not be changed even if an administrative FB is executed while a motion related FB is being executed. However, some motion control FBs can cause a specific state transition.</li> <li>• When multiple instances are executed for an axis or an axes group at the same time, control is preferentially performed from the one whose priority by which to execute the motion control FB is high.</li> </ul> |
| Standard FB       | <ul style="list-style-type: none"> <li>• A motion control FB that does not take an axis or axes group for the argument.</li> <li>• A standard FB can execute multiple instances at the same time. Since it is not related to the axis, it does not affect either motion related FBs or administrative FBs.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The following table lists the priority by which to execute motion control FBs.

—: No priority assignment

| Priority              | Motion control FB |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Execution command (Execute) type/Enable (Enable) type

Some motion control FBs are executed with Execution command (Execute), while others are executed with Enable (Enable).

| Type              | Execution command (Execute) type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Enable (Enable) type                                                                                                                                                                                                                                                                                                                                                                                                                                 | Other types     |

The basic operation of each motion control FB by Execution command (Execute command) and Enable (Enable) is shown below. Note that some motion control FBs have different specifications.

## ■ Basic operation of Execution command (Execute) type motion control FBs

- Execution command (Execute) type FBs read the input parameters at the rising edge of Execution command (Execute) and then start operation. Once operation has started, the operation will be continued until it is completed even if Execution command (Execute) is set to FALSE.
- When operation has started, only one output variable among Executing (Busy), Execution completion (Done), Error (Error), and Abortion of execution (CommandAborted) becomes TRUE.
- Execution completion (Done), Error (Error), Error code (ErrorID), and Abortion of execution (CommandAborted) are reset at the falling edge of Execution command (Execute). Executing (Busy) and Controlling (Active) are not affected.
- When changing the input parameter during operation, the change is reflected at restart (retrigger) of Execution command (Execute) or by continuous update using Continuous update (ContinuousUpdate).
- Analyzing (AxisName.Md.Analyzing/AxesGroupName.Md.Analyzing) becomes TRUE from the rising edge of Executing (Busy), and Analyzing (AxisName.Md.Analyzing/AxesGroupName.Md.Analyzing) becomes FALSE after starting the operation.
- When Execution command (Execute) is used in pulse, Execution completion (Done) becomes TRUE for one cycle only.

**Ex.**

The timing chart for Execution command (Execute) type motion control FBs is shown below.

- When the FB is normal

- When the I/O variables are abnormal

- When the input variables are abnormal

\*1 The following operation is performed when the termination condition of the motion control FB (Execution command (Execute) is FALSE) is met. For motion control FBs not related to the axis or motion control FBs which do not stop with decelerating, Error (Error) becomes TRUE for one cycle only and Error code (ErrorID) is output. For motion control FBs that need to perform a deceleration stop, Error (Error) becomes TRUE until the stop with decelerating and Error code (ErrorID) is maintained. At stop completion of the axis, Error (Error) becomes FALSE and Error code (ErrorID) is cleared.

## ■ Basic operation of Enable (Enable) type motion control FBs

- Enable (Enable) type motion control FBs are continuously executed while Enable (Enable) is TRUE.
- Output value valid (Valid) indicates that the output is a valid value. After Output value valid (Valid) becomes FALSE, each output does not change.
- Only one output variable among Output value valid (Valid)/Enabled (Enabled)/Executing (Busy), Error (Error), and Abortion of execution (CommandAborted) becomes TRUE.
- Analyzing (AxisName.Md.Analyzing/AxesGroupName.Md.Analyzing) becomes TRUE from the rising edge of Executing (Busy), and Analyzing (AxisName.Md.Analyzing/AxesGroupName.Md.Analyzing) becomes FALSE after starting the operation.
- Output variables not listed above are reset on the falling edge of Enable (Enable). (The reset timing is the same as Output value valid (Valid)/Enabled (Enabled)/Executing (Busy), Error (Error), and Abortion of execution (CommandAborted).)

### Ex.

The timing chart for Enable (Enable) type motion control FBs is shown below.

- When the FB is normal

- When the I/O variables are abnormal

- When the input variables are abnormal

## Motion control types

The following types of axis and axes group control can be executed by motion related motion control FBs.

| Large classification | Middle classification | Small classification | Description                                                                                                                                                                                                                                                              |
|----------------------|-----------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Axis control         | Single axis control   | Positioning control  | Control in which Axis status ( <u>AxisName</u> .Md.AxisStatus) is set to "5: During positioning operation (DiscreteMotion)" and the axis is moved to the target position.                                                                                                |
|                      |                       | Continuous control   | Control in which Axis status ( <u>AxisName</u> .Md.AxisStatus) is set to "6: During continuous operation (ContinuousMotion)" and continuous control is performed for the axis.                                                                                           |
|                      |                       | Synchronous control  | Control which has Master axis (Master) and Slave axis (Slave) as I/O variables and performs synchronous control for the axis with the Axis status ( <u>AxisName</u> .Md.AxisStatus) of Slave axis (Slave) set to "7: During synchronous operation (SynchronizedMotion)". |
|                      |                       | Manual control       | Positioning control FBs, continuous control FBs, and synchronous control FBs whose type is Enable (Enable) and whose output variable is Execution completion (Done)                                                                                                      |
|                      |                       | Homing control       | Control in which Axis status ( <u>AxisName</u> .Md.AxisStatus) is set to "3: During home position return (Homing)" and continuous control is performed for the axis.                                                                                                     |
| Axes group control   | Multiple axes control | Positioning control  | Control in which Axes group status ( <u>AxesGroupName</u> .Md.GroupStatus) is set to "5: Operating (GroupMoving)" and the axis is moved to the target position.                                                                                                          |

## Error processing

If an error occurs while the motion control FB is executed, Error (Error) becomes TRUE and the error code is output to Error code (ErrorID). At this time, for an axis, Axis status (AxisName.Md.AxisStatus) transitions to "1: Stopping on error (ErrorStop)", and for an axes group, Axes group status (AxesGroupName.Md.GroupStatus) transitions to "1: Stopping on error (GroupErrorStop)".

When the axis status of an available axis transits to the "1: Stopping on error (ErrorStop)" status, all buffering FBs are aborted. Error (Error) of the aborted motion control FBs becomes TRUE.

After that, an error reset needs to be executed to start the axis or axes group.

For how to check errors of the axis or axes group and how to reset the error, refer to the following.

 User's manual for the controller used

### Point

One of the following values is output to Error code (ErrorID). (The value output depends on the control.) However, event codes are not output.

- Axis error code (AxisName.Md.ErrorID)
- Axes group error code (AxesGroupName.Md.ErrorID)
- Latest motion system error code (MotionSystem.Md.ErrorID)

## Units used in control

Units for the position, velocity, acceleration/deceleration, and jerk that are used in the Motion system follow the technical units of the axis to be used.

The following types exist for the control values, such as the position and the velocity, that are used in the Motion system.

For details on the axis technical units and control values related to the position and the velocity, refer to the following.

 User's manual for the controller used

| Type            | Description                                                                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Commanded value | A value (target value) based on an input to the motion control FB.<br>(Such as commanded position and commanded velocity)                                                               |
| Set value       | The current control value that is generated by Motion operation.<br>(Such as set position and set velocity)                                                                             |
| Actual value    | A value obtained by converting the actual value received from the device station by the real axis into the technical unit of the axis.<br>(Such as actual position and actual velocity) |

## I/O variables used in motion control FBs

This section describes the I/O variables used in motion control FBs.

For motion control FBs, the I/O variables, input variables, and output variables must be defined.

### I/O variables

These variables set the axis and axes group of the drive unit to be controlled, including Axis information (Axis) and Axes group information (AxesGroup).

Axes and axes groups are generated/initialized by setting axis settings and the axes group setting in the engineering tool.

The set axis and axes group are assigned as an axis variable or an axes group variable in the global label data.

For details on the axis and axes groups, refer to the following.

 User's manual for the controller used

### Input variable

These variables set operation conditions such as the target position and the command velocity.

### Output variable

These variables output the motion control FB status, drive unit status, whether there is an error, or other status.

### Class

The following are the classes of the I/O variables, input variables, and output variables.

| Variable        | Class      |
|-----------------|------------|
| I/O variable    | VAR_IN_OUT |
| Input variable  | VAR_INPUT  |
| Output variable | VAR_OUTPUT |

### Data types

Variables are classified into different types based on their bit length, processing method, value range, or others.

For details on data types, refer to the following.

 Page 30 Data Specification Method

### Omission of input arguments

When omitting motion control FB inputs, the default value that is defined for each motion control FB is applied. For details on the default values, refer to the section for the motion control FB to be used.

When omitting inputs such as the velocity in the multiple start motion control FB, the input value of the previous motion control FB is carried over.

### Refresh timing of inputs/outputs

Each argument of the motion control FB is refreshed at the call timing of the motion control FB. To control the input/output of the motion control FB synchronizing with the operation cycle, call the motion control FB from a fixed cycle program whose cycle is the same as the operation cycle.

Specification of I/O No.

When using a motion control FB, the I/O No. must be set in the I/O variables that are used in the motion control FB (example: I/O No. (AxisName.AxisRef.StartIO)). (For input/output variables used in motion control FBs (example: I/O No. (AxisName.AxisRef.StartIO)), only the default value can be used.)

When setting the I/O No., AXIS\_REF of the axis variables or axes group variables (AxisName.AxisRef for axis variables and AxesGroupName.AxesGroupRef for axes group variables) is used.

The members (Axis No. (AxisNo), Axes group No. (GroupNo), I/O No. (StartIO)) in AXIS\_REF of the axis variables and axes group variables already have the I/O No. specified as a structure, so the I/O No. can be set without specification by just setting the axis label.

When setting the I/O No., using the Axis information (AxisName.AxisRef) label to perform the setting is recommended. In addition, any Axis information (AxisName.AxisRef) label can be set.

Ex.

When the label for Axis 1 (Axis0001) is used and MCv\_AllPower (All Axes Operation Available) is executed

\*1 Information for the following members is included in the Axis information (AxisName.AxisRef) label.

| Name          | Setting value | Label name               |
|---------------|---------------|--------------------------|
| Axis No.      | 1             | Axis0001.AxisRef.AxisNo  |
| Start I/O No. | 3E00H         | Axis0001.AxisRef.StartIO |

## Precautions for the motion control FB

- I/O arguments of the motion control FB are refreshed at the call timing of the motion control FB, but the cycle that the control is actually executed in differs depending on the motion control FB. For example, motion related FBs perform the control at the operation cycle regardless of the motion control FB call task (normal/fixed cycle). For details, refer to the section for the motion control FB to be used.
- The timing for refreshing the output arguments of the motion control FBs differs from the timing for refreshing axis variables and other related labels. For this reason, the timing chart provided for each function may not always match the actual signal changes. Create a program considering the refresh cycle of each signal.
- For motion control FBs in operation (Executing (Busy) is TRUE), call the motion control FB. If the motion control FB is not called into the program, control continues. However, changes to the input variable values will not be reflected in control, and it will no longer be possible to update output variables such as errors and Execution Completion.
- Do not use the motion control FB in an initial execution type program as an FB call may stop while the motion control FB is in operation.
- When used between the FOR and NEXT instructions or in combination with a control syntax (IF statement, FOR statement, and CASE statement), check Executing (Busy) and Execution completion (Done) so that the motion control FB is called before the execution of the motion control FB is complete.
- The motion control FB imports input values when Execution command (Execute) or Enable (Enable) is set to TRUE. Therefore, set input values before setting Execution command (Execute) or Enable (Enable) to TRUE. In addition, when changing multiple input arguments by a retrigger/continuous update of the motion control FB, change them by the same task as the motion control FB call task to match the import timing of each argument.
- When changing Execution command (Execute) to FALSE after it has been set to TRUE, wait until after Executing (Busy) has changed to the TRUE status before setting Execution command (Execute) to FALSE.
- The motion control function uses real number data (floating-point data) for the axis current position, motion control FB target position, or others. Therefore, it may include a truncation error. For example, when repeatedly executing positioning in relative position specification, such as with MC\_MoveRelative (Relative Value Positioning), the truncation error may cumulate between the set position and the specified movement value. If the truncation error is a problem, execute positioning in absolute position specification, such as with MC\_MoveAbsolute (Absolute Value Positioning). In addition, the truncation error that occurs in the real number data processing within the function can be suppressed by setting real number type parameters related to the Motion control function so that there is no number after the decimal point. For details on the real number data (floating-point data) used in motion control FBs, refer to the following.

 Page 39 Real number data (floating-point data)

- Do not allow one motion control FB instance to be called from multiple programs (programs to be executed in parallel, including interrupt programs) at the same time. Operation when an instance is called at the same time cannot be guaranteed.

# 43.2 Motion Control FB Configuration

This section describes how to write each program language for the motion control FB.

## Ladder

In the ladder language, the motion control FB is arranged as follows.

Ex.

If MC\_Power (Operation Available)

| Name            | Description                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instance name   | The instance name assigned to each FB.<br>The instance name can be changed.                                                                                                                                                                           |
| I/O variable    | These variables set the axis variable names of the drive unit (or other devices) to be controlled, including Axis information (Axis) and Axes group information (AxesGroup).                                                                          |
| Input variable  | These variables set operation conditions such as the target position and the command velocity.<br>The setting of these variables can be omitted. When omitted, the default value is used.                                                             |
| Output variable | These variables output the FB status and drive unit status.                                                                                                                                                                                           |
| Data type       | Displays the data type of I/O variables, input variables, and output variables.<br>For details on the data type of I/O variables, input variables, and output variables, refer to the following.<br><a href="#">Page 30 Data Specification Method</a> |

## FBD/LD (Function block diagram/ladder)

In the FBD/LD language, the motion control FB is arranged as follows.

**Ex.**

If MC\_Power (Operation Available)

| Name            | Description                                                                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instance name   | The instance name assigned to each FB.<br>The instance name can be changed.                                                                                                               |
| I/O variable    | These variables set the axis variable names of the drive unit (or other devices) to be controlled, including Axis information (Axis) and Axes group information (AxesGroup).              |
| Input variable  | These variables set operation conditions such as the target position and the command velocity.<br>The setting of these variables can be omitted. When omitted, the default value is used. |
| Output variable | These variables output the FB status and drive unit status.                                                                                                                               |

## ST (Structured text)

In the ST language, the Motion control FB is arranged as follows.

**Ex.**

If MC\_Power (Operation Available)

| Name            | Description                                                                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instance name   | The instance name assigned to each FB.<br>The instance name can be changed.                                                                                                               |
| I/O variable    | These variables set the axis variable names of the drive unit (or other devices) to be controlled, including Axis information (Axis) and Axes group information (AxesGroup).              |

# 44 LIST OF MOTION CONTROL FUNCTION BLOCK VARIABLES

This chapter describes the list of variables used in motion control FBs.

## 44.1 List of Variables

The following types of variables are handled in Motion control.

| Variable                              |                          | Description                                                                                                                                             | Reference                                                         |
|---------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| Axis variable                         |                          | Variables for axes configured with parameter data such as the axis type or monitor data such as the axis current position.                              | Page 1444 Axis variables                                          |
| Axes group variable                   |                          | Variables for axes groups configured with parameter data such as configuration axes or monitor data such as the axis group status.                      | Page 1468 Axes group variables                                    |
| System variable                       |                          | Variables for systems configured with parameter data relating to add-ons or monitor data such as the operation cycle.                                   | Page 1475 System variables                                        |
| Advanced synchronous control variable | Input axis variable      | Variables for input axes configured with parameter data for advanced synchronous control input axes or monitor data such as the axis current position   | Page 1479 Input axis variable                                     |
|                                       | Output axis variable     | Variables for output axes configured with parameter data for advanced synchronous control output axes or monitor data such as the axis current position | Page 1481 Output axis variable                                    |
|                                       | System variable          | Variables for systems configured with parameter data relating to advanced synchronous control add-ons or monitor data                                   | Page 1486 System variable (Advanced synchronous control)          |
|                                       | Other structure variable | Variables for structures used in advanced synchronous control that are classified outside those listed above                                            | Page 1507 Other structure variable (Advanced synchronous control) |
| Other structure variable              |                          | Variables for structures in a classification not listed above.                                                                                          | Page 1487 Other structure variables                               |

In this manual, variables listed with a portion of the variable underlined indicates that the variable name is defined by the user.

AxisName.AxisRef.AxisNo

A variable to be defined by the user

## How to read the list of variables

Each item in the list of variables has the following meaning.

### ■Import

| Item                                     | Description                                                                                                                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operation cycle                          | The timing for executing each operation cycle                                                                                                                                                 |
| Normal                                   | The timing for executing normal tasks of the Motion system                                                                                                                                    |
| Service                                  | The timing for executing the motion service processing control                                                                                                                                |
| Immediately                              | When an event occurs                                                                                                                                                                          |
| At start                                 | When the FB starts                                                                                                                                                                            |
| At stop                                  | When the FB stops                                                                                                                                                                             |
| At system start                          | When the Motion system starts                                                                                                                                                                 |
| When connecting device                   | When a device station is connected                                                                                                                                                            |
| Ready ON                                 | When "PLC Ready (MotionSystem.Cd.SequenceReady)" is turned on                                                                                                                                 |
| System basic cycle                       | The timing for executing the system basic cycle processing                                                                                                                                    |
| Operation cycle (GroupEnable)            | The timing for executing each operation cycle (GroupEnable)                                                                                                                                   |
| When axes group is valid                 | The timing when the axes group becomes valid                                                                                                                                                  |
| Operation cycle (FB is starting)         | The timing for executing operation cycle processing (FB is starting)                                                                                                                          |
| When the 0th point of cam data is passed | When the current position of one cycle passes the 0th point of the cam data currently being executed <example><br>The timing of when the 0th point position was passed for cam resolution 512 |

### ■Attribute

| Display         | Description                                           |
|-----------------|-------------------------------------------------------|
| LIST_WRITE_BACK | Label list (Write back to initial value possible)     |
| LIST_READ_ONLY  | Label list (Write back to initial value not possible) |

# Axis variables

Axis variables are assigned the following data types based on the axis type.

| Axis type            | Data type            |
|----------------------|----------------------|
| Real drive axis      | AXIS_REAL            |
| Real encoder axis    | AXIS_ENCODER         |
| Virtual drive axis   | AXIS_VIRTUAL         |
| Virtual encoder axis | AXIS_VIRTUAL_ENCODER |
| Virtual link axis    | AXIS_VIRTUAL_LINK    |

The axis variables that can be set differ depending on the axis type used. ( Page 1463 Variables settable as the axis variable for each axis type)

Each axis data type has the following members.

| Member name | Data type <sup>*1*2</sup> | Description                                                                                                                                                                                                                                         | Reference                                                              |
|-------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| AxisRef     | AXIS_REF                  | The data structure for input/output of the Motion control FBs.<br>The type is fixed regardless of the axis type.                                                                                                                                    | Page 1444 <a href="#">AxisName.AxisRef</a> . (Axis information)        |
| PrConst     | AXIS_□_PRM_CONST          | Stores the axis parameter data (constant).<br>Opens the setting value at the axis variable initialization.<br>Reload to the control is not executed after the axis variable initialization.                                                         | Page 1445 <a href="#">AxisName.PrConst</a> . (Axis parameter constant) |
| Pr          | AXIS_□_PRM                | Stores the axis parameter data.<br>Opens the default value at the axis variable initialization.<br>Reload to the control is executed after the axis variable initialization.<br>The fetch timing to the control changes depending on the parameter. | Page 1449 <a href="#">AxisName.Pr</a> . (Axis parameter)               |
| Md          | AXIS_□_MONI               | Stores the axis monitor data.<br>Executes refresh in the fixed cycle for each monitor data.                                                                                                                                                         | Page 1453 <a href="#">AxisName.Md</a> . (Axis monitor data)            |
| Cd          | AXIS_□_CMD                | Stores the axis control command data.<br>Acquires the latest value every control operation cycle and uses it for the control.                                                                                                                       | Page 1462 <a href="#">AxisName.Cd</a> . (Axis control data)            |

\*1 □: The data type of each axis type

\*2 The members of the data type differ depending on the axis type.

## AxisName.AxisRef. (Axis information)

| Variable name | Name     | Import | Data type  | Attribute           | Description                                                                                                                                                               |
|---------------|----------|--------|------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AxisNo        | Axis No. | —      | WORD(UINT) | LIST_WRIT<br>E_BACK | The axis No. is set.<br>• 0: Not set<br>• 1 to 10000: Set axis No.                                                                                                        |
| StartIO       | I/O No.  | —      | WORD(HEX)  | LIST_WRIT<br>E_BACK | The I/O No. is set.<br>By default, 3E0H is automatically input.<br>• 000H to 0FFH: The start I/O number (the first three digits when expressed in four-digit hexadecimal) |

## AxisName.PrConst. (Axis parameter constant)

## Variables settable as the axis variable for each axis type

The variables that can be set and used as the axis variable differ for each axis type.

The variables that can be set for each axis type are shown below.

### ■AxisName.AxisRef. (Axis information)

○: Can be set, ×: Cannot be set

| Variable name | Name     | Axis type       |                   |                    |                      |                   |
|---------------|----------|-----------------|-------------------|--------------------|----------------------|-------------------|
|               |          | Real drive axis | Real encoder axis | Virtual drive axis | Virtual encoder axis | Virtual link axis |
| AxisNo        | Axis No. | ○               | ○                 | ○                  | ○                    | ○                 |
| StartIO       | I/O No.  | ○               | ○                 | ○                  | ○                    | ○                 |

### ■AxisName.PrConst. (Axis parameter constant)

○: Can be set, ×: Cannot be set

| Variable name                | Name                                          | Axis type       |                   |                    |                      |                   |
|------------------------------|-----------------------------------------------|-----------------|-------------------|--------------------|----------------------|-------------------|
|                              |                                               | Real drive axis | Real encoder axis | Virtual drive axis | Virtual encoder axis | Virtual link axis |
| AddressOfStation             | Station address setting                       | ○               | ○                 | ×                  | ×                    | ×                 |
| AxisType                     | Axis type setting                             | ○               | ○                 | ○                  | ○                    | ○                 |
| Encoder_AxisType             | Real encoder axis type setting                | ×               | ○                 | ×                  | ×                    | ×                 |
| Encoder_CounterDisableSignal | Counter disabling signal                      | ×               | ○                 | ×                  | ○                    | ×                 |
| Encoder_RingCout_LowerValue  | Encoder ring counter lower limit value        | ×               | ×                 | ×                  | ○                    | ×                 |
| Encoder_RingCout_UpperValue  | Encoder ring counter upper limit value        | ×               | ×                 | ×                  | ○                    | ×                 |
| HwStrokeLimit_FlsSignal      | Upper limit signal                            | ○               | ×                 | ○                  | ×                    | ×                 |
| HwStrokeLimit_RlsSignal      | Lower limit signal                            | ○               | ×                 | ○                  | ×                    | ×                 |
| OperationCycle               | Control cycle setting                         | ○               | ○                 | ○                  | ○                    | ○                 |
| PosRestoration_AbsPosEnable  | Absolute position control setting             | ○               | ○                 | ○                  | ○                    | ○                 |
| RingCount_Enable             | Ring counter enabled selection                | ○               | ○                 | ○                  | ○                    | ○                 |
| RingCount_LowerValue         | Ring counter lower limit value                | ○               | ○                 | ○                  | ○                    | ○                 |

# Axes group variables

The data type of axes group variables is expressed as AXES\_GROUP.

Each axes group data type has the following members.

| Member name  | Data type            | Description                                                                                                                                                                                                                                                  | Reference                                                                            |
|--------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| AxesGroupRef | AXES_GROUP_REF       | The data structure for input/output of the Motion control FBs.                                                                                                                                                                                               | Page 1468<br><a href="#">AxesGroupName.AxesGroupRef</a> . ## System variables

The data type of system variables is expressed as MT\_SYSTEM type.

The system data type has the following members.

| Member name | Data type | Description                                                                                                                                                                                             | Reference                                                          |

## Input axis variable

The data type of input axis variables to be used for advanced synchronous control is expressed as the ADV\_INPUT type. Each input axis data type has the following members.

| Member name | Data type           | Description                                                                                                                                                                                                                                                                                   | Reference                                                                        |
|-------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| LabelID     | WORD (UINT)         | The input axis label ID is set.                                                                                                                                                                                                                                                               | Page 1479 <a href="#">AdvInputName</a> . (Input axis setting)                    |
| Axis        | AXIS_REF            | The axis to be the input axis for advanced synchronous control is set. An identical axis cannot be specified for multiple input axis information.                                                                                                                                             |                                                                                  |
| PrConst     | ADV_INPUT_PRM_CONST | The parameter data (constant) of the axis to be the input axis is stored. The setting value at the input axis variable initialization is opened. Reload to the control is not executed after the input axis variable initialization.                                                          | Page 1480 <a href="#">AdvInputName.PrConst</a> . (Input axis parameter constant) |
| Pr          | ADV_INPUT_PRM       | The parameter data of the axis to be the input axis is stored. The default value at the input axis variable initialization is opened. Reload to the control is not executed after the input axis variable initialization. The fetch timing to the control changes depending on the parameter. | Page 1480 <a href="#">AdvInputName.Pr</a> . (Input axis parameter)               |
| Md          | ADV_INPUT_MONI      | The monitor data of the axis to be the input axis is stored. Refresh in the fixed cycle is executed for each monitor data.                                                                                                                                                                    | Page 1480 <a href="#">AdvInputName.Md</a> . (Input axis monitor data)            |

| Axis          | Axis information | At system start | AXIS_REF<br> Page 1444<br><a href="#">AxisName.AxisRef</a> . (Axis information) | LIST_WRITE<br>_BACK | Axis information ( <a href="#">AxisName.AxisRef</a> ) of an axis to be the input axis for advanced synchronous control is set. The maximum number of input axes that can be generated is 256. An identical axis cannot be set for the axis information on different input axes. If it is set, Advanced Synchronous Control Input Axis Incorrect (error code: 1A0EH) will occur. Do not set Axis information ( <a href="#">AxisName.AxisRef</a> ) to an axis defined with a local label. Doing so prevents the input axis from being generated. |

## AdvInputName.PrConst. (Input axis parameter constant)

| Variable name                 | Name                             | Import          | Data type                                                                                                                                        | Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| CumulativePosition         | Cumulative current position         | Operation cycle | LREAL     | LIST_READ<br>_ONLY | The position unit of the input axis whose cumulative current position is set to Axis information (AdvInputName.Axis) on the input axis is set.<br>The current position of the input axis is a value after smoothing processing, phase compensation processing, and moving direction restriction processing. |
| SetVelocity                | Set velocity                        | Operation cycle | LREAL     | LIST_READ<br>_ONLY | The speed unit of the input axis whose speed is set to Axis information (AdvInputName.Axis) on the input axis is stored.<br>The speed of the input axis is a value after smoothing processing, phase compensation processing, and moving direction restriction processing.                                  |
| PhaseCompensationAmount    | Phase compensation amount           | Operation cycle | LREAL     | LIST_READ<br>_ONLY | The position command unit of the input axis whose phase compensation amount is set to Axis information (AdvInputName.Axis) on the input axis is stored.<br>The phase compensation amount of the input axis is a value after smoothing processing and phase compensation processing.                         |
| DirectionRestrictionAmount | Moving direction restriction amount | Operation cycle | LREAL     | LIST_READ<br>_ONLY | The position unit of the axis whose cumulative value of the input movement amount in the direction opposite to the permitted direction is set to the input axis when the moving direction of the input axis is restricted is stored.                                                                        |

## Output axis variable

The data type of output axis variables to be used for advanced synchronous control is expressed as the ADV\_OUTPUT type. Each output axis data type has the following members.

| Member name | Data type            | Description                                                                                                                                                                                                                                                                                  | Reference                                                                 |
|-------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| LabelID     | WORD (UINT)          | The output axis label ID is set.                                                                                                                                                                                                                                                             | Page 1481 <u>AdvOutputName</u> . (Output axis setting)                    |
| AxisRef     | AXIS_REF             | The axis to be the output axis for advanced synchronous control is set. An identical axis cannot be specified for multiple output axis information.                                                                                                                                          |                                                                           |
| PrConst     | ADV_OUTPUT_PRM_CONST | The parameter data (constant) of the axis to be the output axis is stored. The setting value at the output axis variable initialization is opened. Reload to the control is not executed after the output axis variable initialization.                                                      | Page 1482 <u>AdvOutputName.PrConst</u> . (Output axis parameter constant) |
| Pr          | ADV_OUTPUT_PRM       | The parameter data of the axis to be the output axis is stored. The default value at the output axis variable initialization is opened. Reload to the control is executed after the output axis variable initialization. The fetch timing to the control changes depending on the parameter. | Page 1483 <u>AdvOutputName.Pr</u> . (Output axis parameter)               |
| Md          | ADV_OUTPUT_MONI      | The monitor data of the axis to be the output axis is stored. Refresh in the fixed cycle is executed for each monitor data.                                                                                                                                                                  | Page 1485 <u>AdvOutputName.Md</u> . (Output axis monitor data)            |
| Cd          | ADV_OUTPUT_CMD       | The output axis control command data is stored. The latest value is acquired for every control operation cycle and used for the control.                                                                                                                                                     | Page 1485 <u>AdvOutputName.Cd</u> . (Output axis control data)            |

| Axis          | Axis information | At system start | AXIS_REF<br> Page 1444<br><u>AxisName.AxisRef</u> . (Axis information) | LIST_WRITE _BACK | Axis information ( <u>AxisName.AxisRef</u> ) of an axis to be the output axis for advanced synchronous control is set. The maximum number of output axes that can be generated is 256. An identical axis cannot be set for the axis information on different output axes. If it is set, Advanced Synchronous Control Output Axis Incorrect (error code: 1A0FH) will occur. Do not set Axis information ( <u>AxisName.AxisRef</u> ) to an axis defined with a local label. Doing so prevents the output axis from being generated. The axis types that can be set as output axes are real drive axes, virtual drive axes, and virtual linked axes. If an unavailable axis is set, Advanced Synchronous Control Output Axis Incorrect (error code: 1A0FH) will occur. |

## AdvOutputName.PrConst. (Output axis parameter constant)

| Variable name                              | Name                                                     | Import          | Data type   | Attribute       | Description                                                                                                                                                                                                                                                                                                                                          |

## System variable (Advanced synchronous control)

The data type of system variables is expressed as SYSTEM type.

The system data type has the following members.

| Member name | Data type | Description                                                                                                                                                                                             | Reference                                                         |
|-------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| PrConst     | SYS_CONST | Stores the parameter data (constant) for the system.<br>Opens the setting value at system variable initialization.<br>Does not execute reimporting to the control after system variable initialization. | Page 1486 AddonSystem.PrConst. (Add-on system parameter constant) |
| Md          | SYS_MONI  | Stores the monitor data for the system.<br>Executes refresh in the fixed cycle for each monitor data.                                                                                                   | Page 1486 AddonSystem.Md. (Add-on system monitor data)            |

| [CONST]        | Constant                                                                    | [CONST]Constant<br>[CONST]0xConstant | <p>Sets a floating decimal (E format is also available), decimal integer, or hexadecimal integer.</p> <p>* This data cannot be written.</p>                                                                                                                                                                                                                                            | <p>[CONST]1000</p> <p>[CONST]0x100</p>                                                                 |

\*2 This is written when explicitly setting the data type. The following data types can be set.  
When "(BOOL)" is specified for data set in Classification having a data type other than BOOL type, it will be handled as though 0 was specified for the specification target bit number.

| Type    |
|---------|
| (BOOL)  |
| (INT)   |
| (DINT)  |
| (WORD)  |
| (DWORD) |
| (REAL)  |
| (LREAL) |

\*3 When the bit position is added to data of the [Classification] shown below, the data is handled as though it is BOOL type.  
When (Type) and the bit position are both set, the setting for (Type) is ignored and the data becomes BOOL type data.

| Classification                                          | Bit position setting range |
|---------------------------------------------------------|----------------------------|
| [OBJ]                                                   | 0 to F                     |
| [VAR] (only WORD type, DWORD type, INT type, DINT type) |                            |
| [DEV]                                                   |                            |

\*4 The auxiliary information used for specifying the data is set. The details differ depending on the set [Classification].  
Certain functions that use signals require the target modification to be set. When specifying the target modification for data types and functions that do not require it, the specification will be ignored.

| Classification | Target modification                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Setting example                                         |

| [CONST]        | @+adding value<br>@-subtracting value | <p>Used to change the read value each time the value is referred.<br/>Setting the target modification allows the value to be changed each cycle.<br/>When the data type is REAL or LREAL, this setting is invalid.</p>                                                                                                                                                                                                                                                                                                  | <p>[CONST](INT)0@-10*6<br/>[CONST](BOOL)0x00.3@+1*7</p> |

\*5 The following enumerators can be set.

○: Can be set, ×: Cannot be set

| MC_SOURCE type enumerator                      | Description                              | Modification |                |
|------------------------------------------------|------------------------------------------|--------------|----------------|
|                                                |                                          | @Position    | @CumulativePos |
| 1: Set value (mcSetValue)                      | Set value of previous operation cycle    | ○            | ○              |
| 2: Actual value (mcActualValue)                | Actual value of previous operation cycle | ○            | ×              |
| 101: Latest set value (mcLatestSetValue)       | Set value of latest operation cycle      | ○            | ○              |
| 102: Latest actual value (mcLatestActualValue) | Actual value of latest operation cycle   | ○            | ×              |

\*6 The referred value will be as "0, -10, -20, -30, ...".

\*7 The referred value switches between TRUE/FALSE every eight (2<sup>3</sup>) cycles. (Adds 1 byte value "+1" every cycle, then retrieves the status of bit 3.)  
Values from 0 to 7 can be used for bit specification for [CONST].

\*8 When setting to a format with more than 63 characters, use WSTRING type labels and use the following method to perform the setting.  
(1) Declare the WSTRING type global label in the Motion system, and store the following portion: Data name.Bit position@Target modification.  
(2) Set the label name from (1) as the WSTRING type label of TARGET\_REF. (Add "^" to the end of the name to indicate reference.)

## ■List of supported devices for [DEV] type

A list of supported devices for [DEV] type is shown below.

R: Only read is available, RW: Read and write are available, —: Not supported

| Device type                     | Device name                                 | Symbol | Supported          |
|---------------------------------|---------------------------------------------|--------|--------------------|
| User device                     | Input                                       | X      | RW <sup>*1,2</sup> |
|                                 | Direct access input                         | DX     | —                  |
|                                 | Output                                      | Y      | RW <sup>*1,2</sup> |
|                                 | Direct access output                        | DY     | —                  |
|                                 | Internal relay                              | M      | RW <sup>*2</sup>   |
|                                 | Latch relay                                 | L      | RW <sup>*2</sup>   |
|                                 | Link relay                                  | B      | RW <sup>*2</sup>   |
|                                 | Link special relay                          | SB     | RW <sup>*2</sup>   |
|                                 | Annunciator                                 | F      | R                  |
|                                 | Edge relay                                  | V      | —                  |
|                                 | Timer                                       | T      | R <sup>*3</sup>    |
|                                 | Retentive timer                             | ST     | R <sup>*3</sup>    |
|                                 | Long timer                                  | LT     | R <sup>*3</sup>    |
|                                 | Long retentive timer                        | LST    | R <sup>*3</sup>    |
|                                 | Counter                                     | C      | R <sup>*3</sup>    |
|                                 | Long counter                                | LC     | R <sup>*3</sup>    |

\*1 Only unassigned devices can be used.

\*2 When the device is set as a refresh target in refresh settings, whether the device station is connected is monitored. For the operation when the device station is disconnected, refer to the following.

 User's manual for the controller used

When the device is set as a refresh target in "Refresh Settings", the signals available are only those of devices whose "Network Synchronous Communication" is set to "Synchronous".

\*3 Timer, retentive timer, long timer, long retentive timer, counter, and long counter have a contact (S), coil (C), and current value (N). When specifying them as the data name, specify as follows: Contact: "Device symbol S", Coil: "Device symbol C", Current value: "Device symbol N"

To specify the contact of retentive timer ST10 to the data name: [DEV]STS10

To specify the current value of long counter LC10 to the data name: [DEV]LCN10

When using timer, retentive timer, long timer, long retentive timer, counter, or long counter, specify the type in accordance with the device size.

\*4 Supported only when the buffer memory of the motion function part or CC-Link IE TSN function part of the controller is specified.

\*5 Supported only when the CPU buffer memory of the controller is specified.

## SIGNAL\_SELECT (Signal select)

| Variable name    | Name                    | Data type                                                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                          |

\*1 When the end point exceeds the length per cycle before reaching the final section, the section number at the time is determined as the final section number and the end point is overwritten with the length per cycle.

\*2 The setting items used to read/write differ depending on Specifying interpolation method of the operation profile data.

## PROFILE\_ROTARY\_CUTTER

| Variable name         | Name (device offset)                         | Data type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

\*1 Errors due to setting values do not occur during writing. An error occurs if the setting is out of range when an operation profile data control FB uses a written open area.

\*2 If Target (Target) is a zero-length string (""), the applicable skip signal is handled without any setting.

\*3 If [OBJ] is set, the target modification cannot be omitted. If it is omitted, Operation profile data control profile ID setting incorrect warning (event code: 00D48H) occurs.

## SLAVE\_OBJECT\_REAL (for system)

Do not use this variable because it is for the system.

| Variable name                        | Name                                 | Data type   | Description                                                                                                         |

| SupportedDriveModes                  | SupportedDriveModes                  | WSTRING(63) | The control mode supported by the drive unit is acquired.                                                           |
| TargetPos                            | TargetPos                            | WSTRING(63) | The command position to be output to the drive unit                                                                 |
| TargetTorque                         | TargetTorque                         | WSTRING(63) | The command torque to be output to the drive unit                                                                   |
| TargetVelocity                       | TargetVelocity                       | WSTRING(63) | The command velocity to be output to the drive unit                                                                 |
| TargetActualValue                    | TorqueActualValue                    | WSTRING(63) | The current torque of the drive unit                                                                                |
| VelActualValue                       | VelActualValue                       | WSTRING(63) | The current speed of the drive unit                                                                                 |
| vControlDi1                          | ControlDi1                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vControlDi2                          | ControlDi2                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vControlDi3                          | ControlDi3                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vControlDi4                          | ControlDi4                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vControlDi5                          | ControlDi5                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vControlDi6                          | ControlDi6                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vControlDi7                          | ControlDi7                           | WSTRING(63) | The input device is set to the drive unit.                                                                          |
| vCurrentAlarm                        | CurrentAlarm                         | WSTRING(63) | The occurring alarm is acquired from the drive unit.                                                                |
| vEncoderStatus1                      | EncoderStatus1                       | WSTRING(63) | The encoder status is acquired from the drive unit.                                                                 |
| vHomeAbsCounter                      | HomeAbsCounter                       | WSTRING(63) | The encoder multiple revolution counter saved as the home position is acquired from the drive unit.                 |
| vHomeCycleCounter                    | HomeCycleCounter                     | WSTRING(63) | The encoder position within one revolution at power-on is acquired from the drive unit.                             |
| vInitialAbsCounter                   | InitialAbsCounter                    | WSTRING(63) | The encoder multiple revolution counter at power-on is acquired from the drive unit.                                |
| vInitialCycleCounter                 | InitialCycleCounter                  | WSTRING(63) | The encoder position within one revolution at power-on is acquired from the drive unit.                             |
| vInitialPos                          | InitialPos                           | WSTRING(63) | The current position at power-on is acquired from the drive unit.                                                   |
| vMaxAbsCounter                       | MaxAbsCounter                        | WSTRING(63) | The maximum value of the encoder multiple revolution counter is acquired from the drive unit.                       |
| vStatusDo1                           | StatusDo1                            | WSTRING(63) | The output device status of the drive unit is acquired.                                                             |

| Variable name                           | Name                                   | Data type   | Description                                                                                          |
|-----------------------------------------|----------------------------------------|-------------|------------------------------------------------------------------------------------------------------|

| vSupportedControlDi1                    | SupportedControlDi1                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedControlDi2                    | SupportedControlDi2                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedControlDi3                    | SupportedControlDi3                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedControlDi4                    | SupportedControlDi4                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedControlDi5                    | SupportedControlDi5                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedControlDi6                    | SupportedControlDi6                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedControlDi7                    | SupportedControlDi7                    | WSTRING(63) | The input device supported by the drive unit is acquired.                                            |
| vSupportedStatusDo1                     | SupportedStatusDo1                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSupportedStatusDo2                     | SupportedStatusDo2                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSupportedStatusDo3                     | SupportedStatusDo3                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSupportedStatusDo4                     | SupportedStatusDo4                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSupportedStatusDo5                     | SupportedStatusDo5                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSupportedStatusDo6                     | SupportedStatusDo6                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSupportedStatusDo7                     | SupportedStatusDo7                     | WSTRING(63) | The output device supported by the drive unit is acquired.                                           |
| vSyncAbsCounter                         | SyncAbsCounter                         | WSTRING(63) | The multiple revolution counter of the scale measurement encoder is acquired from the drive unit.    |
| vSyncCycleCounter                       | SyncCycleCounter                       | WSTRING(63) | The position within one revolution of the scale measurement encoder is acquired from the drive unit. |
| vVelLimitValue                          | VelLimitValue                          | WSTRING(63) | The velocity limit value is set to the drive unit.                                                   |
| vWatchDogCounterDI                      | WatchDogCounterDI                      | WSTRING(63) | The watchdog counter value is notified to the drive unit.                                            |
| vWatchDogCounterUI                      | WatchDogCounterUI                      | WSTRING(63) | The watchdog counter value is acquired in the drive unit.                                            |
| vEncoderStatus2                         | EncoderStatus2                         | WSTRING(63) | The scale measurement encoder status is acquired from the drive unit.                                |
| vScaleCycleCounter                      | ScaleCycleCounter                      | WSTRING(63) | The position within one revolution of the scale measurement encoder is acquired from the drive unit. |
| vScaleAbsCounter                        | ScaleAbsCounter                        | WSTRING(63) | The multiple revolution counter of the scale measurement encoder is acquired from the drive unit.    |
| vScaleMeasurementEncoderResolution      | ScaleMeasurementEncoderResolution      | WSTRING(63) | The scale measurement encoder resolution is acquired from the drive unit.                            |
| vScaleMeasurementEncoderReceptionStatus | ScaleMeasurementEncoderReceptionStatus | WSTRING(63) | The encoder position within one revolution is acquired from the drive unit.                          |

## SLAVE\_OBJECT\_ENCODER

| Variable name  | Name           | Data type   | Description                                                                                                                          |
|----------------|----------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------|
| PosActualValue | PosActualValue | WSTRING(63) | The data storing the synchronous encoder input is set.<br>When the I/O device is connected, imports the value from the set location. |

## SLAVE\_OBJECT\_VIRTUAL\_ENCODER

| Variable name  | Name           | Data type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|----------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PosActualValue | PosActualValue | WSTRING(63) | <p>The data used as the encoder input value is set in the string format.<br/>[VAR], [DEV], and [CONST] can be specified for the type.</p> <p>■ When [VAR] is set</p> <ul style="list-style-type: none"> <li>• Sets data of the (INT), (DINT), (WORD), and (DWORD) data types.</li> <li>• When [VAR] is used, local labels cannot be set.</li> </ul> <p>■ When [DEV] or [CONST] is set</p> <ul style="list-style-type: none"> <li>• Sets data of the (INT), (DINT), (WORD), and (DWORD) data types.</li> </ul> <p>* When this setting is omitted, Encoder input value (<u>AxisName</u>.Cd.Encoder_InputValue) is used.</p> |

## 44.2 List of Enumerators

This section lists enumerators used for various parameters, monitor data, and motion control FBs.

### ENUM enumerators

The enumeration type constant used for various parameters, monitor data, and Motion control FBs actually uses INT type values.

"Enumeration type name\_\_enumerator" INT type global labels are available on the engineering tool.

**Ex.**

When using MC\_BUFFER\_MODE type enumerator "mcBuffered" on the engineering tool

- When using an INT type global label: Set "MC\_BUFFER\_MODE\_\_mcBuffered".

#### MC\_BUFFER\_MODE

| Enumerator         | Setting value | Description      |
|--------------------|---------------|------------------|
| mcAborting         | 0             | Aborting         |
| mcBuffered         | 1             | Buffered         |
| mcBlendingLow      | 2             | BlendingLow      |
| mcBlendingPrevious | 3             | BlendingPrevious |
| mcBlendingNext     | 4             | BlendingNext     |
| mcBlendingHigh     | 5             | BlendingHigh     |

#### MC\_EXECUTION\_MODE

| Enumerator      | Setting value | Description           |
|-----------------|---------------|-----------------------|
| mcImmediately   | 0             | Execute immediately   |
| mcQueued        | 1             | Execute at completion |
| mcSpeculatively | 3             | Execute speculatively |

#### MC\_COMBINE\_MODE

| Enumerator | Setting value | Description                        |
|------------|---------------|------------------------------------|
| mcAddAxes  | 0             | Add positions of 2 input axes      |
| mcSubAxes  | 1             | Subtract positions of 2 input axes |

#### MC\_DIRECTION

| Enumerator          | Setting value | Description        |
|---------------------|---------------|--------------------|
| mcPositiveDirection | 1             | Positive direction |
| mcNegativeDirection | 2             | Negative direction |
| mcShortestWay       | 3             | Shortest path      |
| mcCurrentDirection  | 4             | Current direction  |

#### MC\_SOURCE

| Enumerator          | Setting value | Description         |
|---------------------|---------------|---------------------|
| mcSetValue          | 1             | Set value           |
| mcActualValue       | 2             | Actual value        |
| mcLatestSetValue    | 101           | Latest set value    |
| mcLatestActualValue | 102           | Latest actual value |

## MC\_CIRC\_MODE

| Enumerator | Setting value | Description                |
|------------|---------------|----------------------------|
| mcBorder   | 0             | Border point specification |
| mcCenter   | 1             | Center point specification |
| mcRadius   | 2             | Radius specification       |

## MC\_CIRC\_PATHCHOICE

| Enumerator   | Setting value | Description |
|--------------|---------------|-------------|
| mcCW         | 0             | CW          |
| mcCCW        | 1             | CCW         |
| mcShortWay   | 2             | Shortcut    |
| mcLongWay    | 3             | Detour      |
| mcCWLongWay  | 4             | CW detour   |
| mcCCWLongWay | 5             | CCW detour  |

## MC\_START\_MODE

| Enumerator  | Setting value | Description |
|-------------|---------------|-------------|
| mcImmediate | 0             | Immediately |
| mcAbsolute  | 1             | Absolute    |

## MC\_AXIS\_STATUS

| Enumerator         | Setting value | Description                                        |
|--------------------|---------------|----------------------------------------------------|
| Invalid            | -1            | Axis variable not initialized/axis parameter error |
| Disabled           | 0             | Axis disabled                                      |
| ErrorStop          | 1             | Stopping on error                                  |
| Stopping           | 2             | Decelerating to stop                               |
| Homing             | 3             | During home position return                        |
| Standstill         | 4             | Standby                                            |
| DiscreteMotion     | 5             | During positioning operation                       |
| ContinuousMotion   | 6             | During continuous operation                        |
| SynchronizedMotion | 7             | During synchronous operation                       |

## MC\_AXES\_GROUP\_STATUS

| Enumerator     | Setting value | Description                                                    |
|----------------|---------------|----------------------------------------------------------------|
| Invalid        | -1            | Axes group variable not initialized/axes group parameter error |
| GroupDisabled  | 0             | Axes group disabled                                            |
| GroupErrorStop | 1             | Stopping on error                                              |
| GroupStopping  | 2             | Decelerating to stop                                           |
| GroupStandby   | 4             | Standby                                                        |
| GroupMoving    | 5             | Operating                                                      |

## MC\_DRIVE\_MODE

| Enumerator   | Setting value | Description                                      |
|--------------|---------------|--------------------------------------------------|
| NoModeChange | 0             | Do not change                                    |
| hm           | 6             | hm (Homing mode)                                 |
| csp          | 8             | csp (Cyclic synchronous position mode)           |
| csv          | 9             | csv (Cyclic synchronous velocity mode)           |
| cst          | 10            | cst (Cyclic synchronous torque mode)             |
| ct           | -104          | ct (Continuous operation to torque control mode) |

## MC\_VELOCITY\_LIMIT\_MODE

| Enumerator       | Setting value | Description                          |
|------------------|---------------|--------------------------------------|
| Ignore           | 0             | Ignore                               |
| Truncate         | 2             | Truncate                             |
| ImmediateStop    | 3             | Immediate stop                       |
| ClampWithoutRamp | 4             | Clamp (Without ramp at deceleration) |

## MC\_INTERPOLATE\_SPEED\_MODE

| Enumerator         | Setting value | Description          |
|--------------------|---------------|----------------------|
| VectorSpeed        | 0             | Vector speed         |
| LongAxisSpeed      | 1             | Long axis speed      |
| ReferenceAxisSpeed | 2             | Reference axis speed |

## MC\_RECORD\_MODE

| Enumerator  | Setting value | Description              |
|-------------|---------------|--------------------------|
| OneShot     | 0             | One shot mode            |
| RecordCount | 1             | Frequency specified mode |
| RingBuffer  | 2             | Ring buffer mode         |

## MC\_CAM\_CURVE\_TYPE

| Enumerator                  | Setting value | Description               |
|-----------------------------|---------------|---------------------------|
| ConstantSpeed               | 0             | Constant speed            |
| ConstantAcceleration        | 1             | Constant acceleration     |
| DistortedTrapezoid          | 2             | Distorted trapezoid       |
| DistortedSine               | 3             | Distorted sine            |
| DistortedConstantSpeed      | 4             | Distorted constant speed  |
| Cycloid                     | 5             | Cycloid                   |
| FifthCurve                  | 6             | 5th curve                 |
| Trapecloid                  | 7             | Trapecloid                |
| ReverseTrapecloid           | 8             | Reverse trapecloid        |
| DoubleHypotenuse            | 9             | Double hypotenuse         |
| ReverseDoubleHypotenuse     | 10            | Reverse double hypotenuse |
| SingleHypotenuse            | 11            | Single hypotenuse         |
| FifthCurve_SpeedDesignation | 12            | 5th curve (Adjustment)    |

## MC\_AXIS\_TYPE

| Enumerator         | Setting value | Description          |
|--------------------|---------------|----------------------|
| DriveAxis          | 0             | Real drive axis      |
| EncoderAxis        | 2             | Real encoder axis    |
| VirtualDriveAxis   | 3             | Virtual drive axis   |
| VirtualEncoderAxis | 4             | Virtual encoder axis |
| VirtualLinkAxis    | 5             | Virtual link axis    |

## MC\_ENCODER\_AXIS\_TYPE

| Enumerator | Setting value | Description    |
|------------|---------------|----------------|
| Drive      | 1             | Via drive unit |

## MC\_ABS\_SYSTEM

| Enumerator  | Setting value | Description                                       |
|-------------|---------------|---------------------------------------------------|
| ABSDisabled | 0             | Disable absolute position system                  |
| Enabled     | 1             | Enable absolute position system                   |
| Auto        | -1            | Automatic setting (Acquire from connected device) |

## MC\_DRIVE\_STATE

| Enumerator          | Setting value | Description            |
|---------------------|---------------|------------------------|
| NotReadyToSwitchOn  | 0             | Not Ready To Switch On |
| Fault               | 1             | Fault                  |
| FaultReactionActive | 2             | Fault Reaction Active  |
| SwitchOnDisabled    | 3             | Switch On Disabled     |
| ReadyToSwitchOn     | 4             | Ready To Switch On     |
| SwitchedOn          | 5             | Switched On            |
| OperationEnable     | 6             | Operation Enable       |
| QuickStopActive     | 7             | Quick Stop Active      |
| Invalid             | -1            | Invalid                |

## MC\_DECEL\_STOP\_MODE

| Enumerator                 | Setting value | Description                            |
|----------------------------|---------------|----------------------------------------|
| Ignore                     | 0             | Ignore                                 |
| ImmediateStop              | 1             | Immediate stop                         |
| KeepCurrentAcc             | 2             | Keep current acceleration/deceleration |
| AlternativeAcc             | 3             | Alternative acceleration/deceleration  |
| ServoOffAfterImmediateStop | 4             | Servo OFF after immediate stop         |
| ServoOffAfterDecelStop     | 5             | Servo OFF after deceleration to stop   |

## MC\_STOP\_CURVE\_MODE

| Enumerator    | Setting value | Description                 |
|---------------|---------------|-----------------------------|
| OverrideCurve | 1             | Recreate deceleration curve |

## MC\_POS\_SOURCE

| Enumerator          | Setting value | Description           |
|---------------------|---------------|-----------------------|
| Invalid             | -1            | Invalid               |
| SetPosition         | 1             | Set position          |
| FeedMachinePosition | 3             | Feed machine position |

## MC\_ACC\_ZERO\_MODE

| Enumerator          | Setting value | Description                       |
|---------------------|---------------|-----------------------------------|
| ACCError            | -1            | Error (not started)               |
| MaximumAcceleration | 1             | Maximum acceleration/deceleration |

## MC\_SIGNAL\_LOGIC

| Enumerator  | Setting value | Description                              |
|-------------|---------------|------------------------------------------|
| HighLevel   | 0             | Detection at TRUE                        |
| LowLevel    | 1             | Detection at FALSE                       |
| RisingEdge  | 2             | Detection at FALSE → TRUE (rising edge)  |
| FallingEdge | 3             | Detection at TRUE → FALSE (falling edge) |
| BothEdges   | 4             | Detection at rising edge/falling edge    |

## MC\_ERROR\_CLASS

| Enumerator    | Setting value | Description    |
|---------------|---------------|----------------|
| _None         | 0             | None           |
| Warning       | 1             | Warning        |
| MinorError    | 2             | Minor error    |
| ModerateError | 3             | Moderate error |
| MajorError    | 4             | Major error    |

## MC\_EXECUTION\_STATE

| Enumerator | Setting value | Description               |
|------------|---------------|---------------------------|
| Ready      | 0             | Waiting execution request |
| Executing  | 1             | Executing                 |
| Done       | 2             | Execution completed       |
| Error_     | -1            | Error occurrence          |

## MC\_POS\_RESTORE\_STATUS

| Enumerator                 | Setting value | Description                                                             |
|----------------------------|---------------|-------------------------------------------------------------------------|
| NotExecute                 | 0             | Not executed                                                            |
| WaitingRequest             | 1             | Waiting restoration request                                             |
| RestoredInIncSystem        | 2             | Restoration completed by incremental system                             |
| RestoredInAbsSystemUnHomed | 3             | Restored in absolute position system (Home position return uncompleted) |
| RestoredInAbsSystem        | 4             | Restored in absolute position system                                    |

## MC\_AXES\_GROUP\_TYPE

| Enumerator | Setting value | Description |
|------------|---------------|-------------|
| Standard   | 0             | Standard    |

## MC\_OPERATION\_PATTERN

| Enumerator                 | Setting value | Description                        |
|----------------------------|---------------|------------------------------------|
| PositioningComplete        | 0             | Positioning completed              |
| ContinuousPositioning      | 1             | Continuous positioning             |
| ContinuousBlendingLow      | 2             | Continuous path (BlendingLow)      |
| ContinuousBlendingPrevious | 3             | Continuous path (BlendingPrevious) |
| ContinuousBlendingNext     | 4             | Continuous path (BlendingNext)     |
| ContinuousBlendingHigh     | 5             | Continuous path (BlendingHigh)     |

## MC\_CONTROL\_METHOD

| Enumerator       | Setting value | Description                           |
|------------------|---------------|---------------------------------------|
| NOP              | 128           | NOP                                   |
| JUMP             | 130           | JUMP                                  |
| LOOP             | 131           | LOOP                                  |
| LEND             | 132           | LEND                                  |
| LinearAbsolute   | 257           | Absolute value linear interpolation   |
| LinearRelative   | 258           | Relative value linear interpolation   |
| CircularAbsolute | 259           | Absolute value circular interpolation |
| CircularRelative | 260           | Relative value circular interpolation |
| HelicalAbsolute  | 261           | Absolute value helical interpolation  |
| HelicalRelative  | 262           | Relative value helical interpolation  |

## MC\_MCODE\_OUTPUT\_OVERRIDE

| Enumerator   | Setting value | Description    |
|--------------|---------------|----------------|
| UseFbOptions | 0             | Use FB options |
| WithMode     | 1             | WITH mode      |
| AfterMode    | 2             | AFTER mode     |

## MC\_STEP\_MODE

| Enumerator             | Setting value | Description                |
|------------------------|---------------|----------------------------|
| Ignored                | 0             | Ignore                     |
| StepPerDec             | 1             | Deceleration unit step     |
| StepPerPositioningData | 2             | Positioning data unit step |

## MC\_POS\_RESTORATION\_BASE

| Enumerator     | Setting value | Description             |
|----------------|---------------|-------------------------|
| BackupPosition | 0             | Backup position         |
| HomePosition   | 1             | Home position           |
| Auto           | -1            | Automatic determination |

## MC\_POS\_RESTORATION\_REQUEST

| Enumerator                     | Setting value | Description                                                               |
|--------------------------------|---------------|---------------------------------------------------------------------------|
| NoRequest                      | 0             | No operation                                                              |
| RestorationRequest             | 1             | Current position restoration execution                                    |
| RestorationRequest_EraseAbsPos | 2             | Current position restoration execution in absolute position erased status |

## MC\_INPUT\_DIRECTION

| Enumerator             | Setting value | Description                                                       |
|------------------------|---------------|-------------------------------------------------------------------|
| NoDirectionRestriction | 0             | No moving direction restriction                                   |
| mcPositiveDirection    | 1             | Allowed only when the current position is in increasing direction |
| mcNegativeDirection    | 2             | Allowed only when the current position is in decreasing direction |

## MC\_CLUTCH\_METHOD

| Enumerator         | Setting value | Description                 |
|--------------------|---------------|-----------------------------|
| NoClutch           | 0             | Invalid                     |

| InitialGearPositionPerCycle | 1             | Current position default value per cycle after gear |
| CalculateFromInputAxis      | 2             | Calculated from input axis                          |

## MC\_CAM\_RESTORE\_METHOD

| Enumerator                  | Setting value | Description                            |
|-----------------------------|---------------|----------------------------------------|
| RestorePositionPerCycle     | 0             | Current position restoration per cycle |
| RestoreReferenceSetPosition | 1             | Cam reference position restoration     |
| RestoreCamSetPosition       | 2             | Cam set position restoration           |

## MC\_CAM\_REFERENCE\_METHOD

| Enumerator                  | Setting value | Description                          |
|-----------------------------|---------------|--------------------------------------|
| PreviousPosition            | 0             | Last value                           |
| InitialReferenceSetPosition | 1             | Cam reference position default value |
| CamSetPosition              | 2             | Set position                         |

## MC\_CAM\_CYCLE\_METHOD

| Enumerator                 | Setting value | Description                                          |
|----------------------------|---------------|------------------------------------------------------|
| PreviousPosition           | 0             | Last value                                           |
| InitialPositionPerCycle    | 1             | Current position default value per cycle             |
| MasterGearPositionPerCycle | 2             | Current position per cycle after master axis gear    |
| AuxGearPositionPerCycle    | 3             | Current position per cycle after auxiliary axis gear |

# 45 ADMINISTRATIVE FUNCTION BLOCKS

## 45.1 Axes Group Enabled

### MC\_GroupEnable

This FB changes the specified Axes group status (AxesGroupName.Md.GroupStatus) from "0: Axes group disabled (GroupDisabled)" to "4: Standby (GroupStandby)" and enables the axes group.

| Ladder diagram | FBD/LD | ST                                                                                                                                                                          |

| Error           | Error                | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                               |
| ErrorID         | Error code           | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used                                                                    |

## Processing details

- This FB changes Axes group status (AxesGroupName.Md.GroupStatus) of the AXES\_GROUP\_REF structure from "0: Axes group disabled (GroupDisabled)" to "4: Standby (GroupStandby)".
- MC\_GroupEnable (Axes Group Enabled) is executed when Execution command (Execute) becomes TRUE, and Executing (Busy) becomes TRUE when the processing is started normally.
- When the processing is completed successfully, Execution completion (Done) becomes TRUE and Executing (Busy) becomes FALSE.
- When an error occurs in MC\_GroupEnable (Axes Group Enabled), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- For the axes group state transition, refer to the following.

 User's manual for the controller used

- MC\_GroupEnable (Axes Group Enabled) can be executed only when Axis Status (AxisName.Md.AxisStatus) of all configuration axes is "4: Standby (Standstill)" or "0: Axis disabled (Disabled)".
- Using axes group (AxisName.Md.UseInGroup) becomes TRUE when Axes group status (AxesGroupName.Md.GroupStatus) changes to "4: Standby (GroupStandby)".
- When MC\_GroupEnable (Axes Group Enabled) is executed while another axes group including a configuration axis for which Using axes group (AxisName.Md.UseInGroup) is TRUE is being set, Axes Group Configuration Axis Is in Use (error code: 1BB8H) occurs.
- If the error occurs in any of the configuration axes, Axes group status (AxesGroupName.Md.GroupStatus) changes to "1: Stopping on error (GroupErrorStop)".
- When MC\_GroupEnable (Axes Group Enabled) is executed for an axes group that has already been enabled, Execution completion (Done) becomes TRUE and the execution ends.

## ■Timing chart

- When the processing is completed successfully

- When I/O variables are abnormal

- When the processing is completed with an error

## Precautions

- Axes group No. (GroupNo) of the AXES\_GROUP\_REF structure must be set in advance before MC\_GroupEnable (Axes Group Enabled) is executed.
- MC\_GroupEnable (Axes Group Enabled) can only be executed when Axis status (AxisName.Md.AxisStatus) of all configuration axes set in the axes group is "4: Standby (Standstill)" or "0: Axis disabled (Disabled)".
- If a parameter error occurs at axes group variable initialization, Out of Parameter Range (Axes Group) (error code: 1A61H) occurs. In this case, Axes group status (AxesGroupName.Md.GroupStatus) changes to "-1: Axes group variable not initialized/Axes group parameter error (Invalid)". Refreshing of the monitor data or others is not executed for axes groups whose status is "-1: Axes group variable not initialized/Axes group parameter error (Invalid)". If the axes group is specified by the user program, Out of Axes Group No. Range (error code: 1B84H) occurs.

## Program example

The following is a program example. The axes group enable command (bGroupEnable) is set to TRUE, and Axes group 1 (AxesGroup001) is enabled.

### ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

### ■Labels used

| Label name       | Data type                           | Comment                   |
|------------------|-------------------------------------|---------------------------|
| MC_GroupEnable_1 | MC_GroupEnable                      | Axes Group Enabled FB     |
| bGroupEnable     | Bit                                 | Axes group enable command |
| bDone            | Bit                                 | Execution completion      |
| bBusy            | Bit                                 | Executing                 |
| bError           | Bit                                 | Error                     |
| uwErrorID        | Word [unsigned]/bit string [16-bit] | Error code                |

### ■FBD/LD program

### ■ST program

```
MC_GroupEnable_1(
  AxesGroup:= AxesGroup001.AxesGroupRef ,
  Execute:= bGroupEnable ,
  Done=> bDone ,
  Busy=> bBusy ,
  Error=> bError ,
  ErrorID=> uwErrorID
);
```

### Point

MC\_GroupEnable (Axes Group Enabled) is used in combination with the motion control FB that performs interpolation control. For an example program with interpolation control, refer to the following.

- ☞ Page 1730 Absolute Value Linear Interpolation Control
- ☞ Page 1745 Relative Value Linear Interpolation Control
- ☞ Page 1759 Absolute Value Circular Interpolation Control
- ☞ Page 1776 Relative Value Circular Interpolation Control

## 45.2 Axes Group Disabled

### MC\_GroupDisable

This FB changes the specified Axes group status (AxesGroupName.Md.GroupStatus) to "0: Axes group disabled (GroupDisabled)" and disables the axes group.

| Ladder diagram | FBD/LD | ST                                                                                                                                                                           |
|----------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |        | <pre> MC_GroupDisable(   AxesGroup:= ?AXES_GROUP_REF? ,   Execute:= ?BOOL? ,   Done=&gt; ?BOOL? ,   Busy=&gt; ?BOOL? ,   Error=&gt; ?BOOL? ,   ErrorID=&gt; ?WORD? ); </pre> |

| ErrorID         | Error code           | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used                                                                                   |

## Processing details

- This FB changes Axes group status (AxesGroupName.Md.GroupStatus) of the AXES\_GROUP\_REF structure to "0: Axes group disabled (GroupDisabled)".
- MC\_GroupDisable (Axes Group Disabled) is executed when Execution command (Execute) becomes TRUE, and Executing (Busy) becomes TRUE when the processing is started normally.
- When the processing is completed successfully, Execution completion (Done) becomes TRUE and Executing (Busy) becomes FALSE.
- When an error occurs in MC\_GroupDisable (Axes Group Disabled), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- For the axes group state transition, refer to the following.

 User's manual for the controller used

- MC\_GroupDisable (Axes Group Disabled) can only be executed when Axes Group Status (AxesGroupName.Md.GroupStatus) is "4: Standby (GroupStandby)" or "1: Stopping on error (GroupErrorStop)". When executing MC\_GroupDisable (Axes Group Disabled) while the axes group status is "1: Stopping on error (GroupErrorStop)" and the axes group is in operation, the axes group status transits to "0: Axes group disabled (GroupDisabled)" after the stop completes. When MC\_GroupDisable (Axes Group Disabled) is executed while Axes group status (AxesGroupName.Md.GroupStatus) is other than "4: Standby (GroupStandby)" or "1: Stopping on error (GroupErrorStop)", Axes Group Status Incorrect (Axes Group Disable) (error code: 1AEFH) occurs and the FB being executed stops.
- When Axes Group Status (AxesGroupName.Md.GroupStatus) changes to "0: Axes group disabled (GroupDisabled)", Using Axes Group (AxisName.Md.UseInGroup) of the configuration axis becomes FALSE.
- When MC\_GroupDisable (Axes Group Disabled) is executed for an axes group that has already been disabled, Execution completion (Done) becomes TRUE and the execution ends.

## ■Timing chart

- When the processing is completed successfully

- When I/O variables are abnormal

- When the processing is completed with an error

## Precautions

- Axes group No. (GroupNo) of the AXES\_GROUP\_REF structure must be set in advance before MC\_GroupDisable (Axes Group Disabled) is executed.
- If a parameter error occurs at axes group variable initialization, Out of Parameter Range (Axes Group) (error code: 1A61H) occurs. In this case, Axes group status (AxesGroupName.Md.GroupStatus) changes to "-1: Axes group variable not initialized/Axes group parameter error (Invalid)". Refreshing of the monitor data or others is not executed for axes groups whose status is "-1: Axes group variable not initialized/Axes group parameter error (Invalid)". If the axes group is specified by the user program, Out of Axes Group No. Range (error code: 1B84H) occurs.

## Program example

The following is a program example. The axes group disable command (bGroupDisable) is set to TRUE, and Axes group 1 (AxesGroup001) is disabled.

### ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

### ■Labels used

| Label name        | Data type                           | Comment                    |
|-------------------|-------------------------------------|----------------------------|
| MC_GroupDisable_1 | MC_GroupDisable                     | Axes Group Disabled FB     |
| bGroupDisable     | Bit                                 | Axes group disable command |
| bDone             | Bit                                 | Execution completion       |
| bBusy             | Bit                                 | Executing                  |
| bError            | Bit                                 | Error                      |
| uwErrorID         | Word [unsigned]/bit string [16-bit] | Error code                 |

### ■FBD/LD program

### ■ST program

```
MC_GroupDisable_1(
  AxesGroup:= AxesGroup001.AxesGroupRef ,
  Execute:= bGroupDisable ,
  Done=> bDone ,
  Busy=> bBusy ,
  Error=> bError ,
  ErrorID=> uwErrorID
);
```

#### Point

MC\_GroupDisable (Axes Group Disabled) is used in combination with the motion control FB that performs interpolation control. For an example program with interpolation control, refer to the following.

- Page 1730 Absolute Value Linear Interpolation Control
- Page 1745 Relative Value Linear Interpolation Control
- Page 1759 Absolute Value Circular Interpolation Control
- Page 1776 Relative Value Circular Interpolation Control

## 45.3 Operable

### MC\_Power

This FB switches a specified axis to the operation available status.

| Ladder diagram | FBD/LD | ST                                                                                                                                                                                                           |
|----------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |        | <pre> MC_Power(   Axis:= ?AXIS_REF? ,   Enable:= ?BOOL? ,   ServoON:= ?BOOL? ,   Status=&gt; ?BOOL? ,   ReadyStatus=&gt; ?BOOL? ,   Busy=&gt; ?BOOL? ,   Error=&gt; ?BOOL? ,   ErrorID=&gt; ?WORD? ); </pre> |

#### ■I/O variables

| I/O variable | Name             | Data type | Input  | Setting range | Default value         | Description                                                                                                                                                                                                                                                                                                                        |
|--------------|------------------|-----------|--------|---------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Axis         | Axis information | AXIS_REF  | Always | —             | Omission not possible | <p>An axis is specified.</p> <p>For the variable (<u>AxisName</u>.AxisRef.) used, refer to the following.</p> <p>☞ Page 1444 <u>AxisName</u>.AxisRef. (Axis information)</p> <p>* The axis information is established when the FB is called for the first time after "PLC Ready (MotionSystem.Cd.SequenceReady)" is turned on.</p> |

#### ■Input variables

| Input variable | Name             | Data type | Input  | Setting range | Default value | Description                                                                                                                                                                                           |
|----------------|------------------|-----------|--------|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable         | Enable           | BOOL      | Always | TRUE, FALSE   | FALSE         | <p>When this variable is set to TRUE, control of the specified axis is enabled (operation possible status).</p> <p>When this variable is set to FALSE, control of the specified axis is disabled.</p> |
| ServoON        | Servo ON request | BOOL      | Always | TRUE, FALSE   | FALSE         | <p>When this variable is set to TRUE, the servo ON is requested to the specified axis.</p>                                                                                                            |

#### ■Output variables

| Output variable | Name            | Data type  | Default value | Description                                                                                                                                                                  |
|-----------------|-----------------|------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status          | Operable        | BOOL       | FALSE         | This variable becomes TRUE when the axis becomes operation possible status.                                                                                                  |
| ReadyStatus     | Ready ON status | BOOL       | FALSE         | This variable becomes TRUE when Driver READY turns on.                                                                                                                       |
| Busy            | Executing       | BOOL       | FALSE         | This variable becomes TRUE when MC_Power (Operation Available) is executed.                                                                                                  |
| Error           | Error           | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                             |
| ErrorID         | Error code      | WORD(UINT) | 0             | <p>When an error occurs, this variable returns the error code.</p> <p>For details on error codes, refer to the following.</p> <p>☞ User's manual for the controller used</p> |

## Processing details

- This FB initializes the information of the specified axis and switches the axis to the operation possible status.
- When the inputs for Enable (Enable) and Servo ON request (ServoON) are TRUE, the selected axis is switched to the operation possible status.
- Executing (Busy) becomes TRUE when the processing is started.
- Operable (Status) becomes TRUE when the drive unit has been switched to the operation possible status.
- When an error occurs in MC\_Power (Operation Available), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- Axis status (AxisName.Md.AxisStatus) of the AXIS\_MONI structure transits from "0: Axis disabled (Disabled)" to "4: Standby (Standstill)". For the axis state transition, refer to the following.

 User's manual for the controller used

- Inputting Enable (Enable) and Servo ON request (ServoON) switches the servo ON/OFF status and the drive unit status of the axis as shown below.

| Input variable  |                            | Output variable               |                   | Servo ON/OFF status | Driver status<br>( <u>AxisName</u> .Md.Driver_State) |
|-----------------|----------------------------|-------------------------------|-------------------|---------------------|------------------------------------------------------|
| Enable (Enable) | Servo ON request (ServoON) | Ready ON status (ReadyStatus) | Operable (Status) |                     |                                                      |
| TRUE            | TRUE                       | TRUE                          | TRUE              | Servo ON            | 6: Operation Enable (OperationEnable)                |
|                 | FALSE                      | TRUE                          | FALSE             | Servo OFF           | 5: Switched On (SwitchedOn)                          |
| FALSE           | TRUE                       | FALSE                         | FALSE             | Servo OFF           | 3: Switched On Disabled (SwitchOnDisabled)           |
|                 | FALSE                      | FALSE                         | FALSE             | Servo OFF           | 3: Switched On Disabled (SwitchOnDisabled)           |

- If the real axis is rotated by external force during the servo OFF status, follow up processing is performed.
- The servo ON/OFF control can be operated regardless of the control mode. The control mode during servo OFF depends on the specifications of the drive unit.
- MC\_Power (Operation Available) is sent to the drive unit while a drive unit error is occurring, so Enable (Enable) and Servo ON request (ServoON) do not need to be turned from FALSE to TRUE again.

## ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

## Precautions

- Axis No. (AxisNo) of the AXIS\_REF structure must be set in advance before MC\_Power (Operation Available) is executed.
- MC\_Power (Operation Available) establishes the axis information the first time that the FB is called after "PLC Ready (MotionSystem.Cd.SequenceReady)" is switched to on. Changes made to the axis information while Enable (Enable) is FALSE are not reflected.
- Do not set two or more MC\_Power (Operation Available) for one axis. The operation is not guaranteed if two or more of this FB are set.
- The servo ON/OFF status when stopping the program is maintained while Built-in motion ready (X420) is off.

## Program example

The following is a program example. The servo ON request command (bServoON) is set to TRUE, and Axis 1 (Axis0001) is switched to the operation possible status.

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name   | Data type                           | Comment                  |
|--------------|-------------------------------------|--------------------------|
| MC_Power_1   | MC_Power                            | Operation Available FB   |
| bServoON     | Bit                                 | Servo ON request command |
| bStatus      | Bit                                 | Operable                 |
| bReadyStatus | Bit                                 | Ready ON status          |
| bBusy        | Bit                                 | Executing                |
| bError       | Bit                                 | Error                    |

\*1 The FB is executed after the previous FB is completed.

\*2 The FB can be executed only when there is no running FB on the specified axis.

## ■Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                   |
|-----------------|-----------------------|------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the current position change is completed.                                                                                                                                                                     |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MC_SetPosition (Current Position Change) is executed.                                                                                                                                                         |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_SetPosition (Current Position Change) is aborted.                                                                                                                                             |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                              |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |
| CancelAccepted  | Cancel acceptance     | BOOL       | FALSE         | This variable becomes TRUE when MC_SetPosition (Current Position Change) accepted the cancel.                                                                                                                                                 |

## Processing details

- This FB changes the current position of the specified axis.
- When Relative position selection (Relative) is TRUE, changes the current position to a position obtained by adding the target position (relative distance) to the current position.
- When Relative position selection (Relative) is FALSE, changes current position to the target position (absolute position).
- MC\_SetPosition (Current Position Change) is executed when Execution command (Execute) becomes TRUE, and Executing (Busy) becomes TRUE when the processing is started normally.
- When the processing is completed and the current position is changed, Execution completion (Done) becomes TRUE.
- When Axis status (AxisName.Md.AxisStatus) becomes "0: Axis disabled (Disabled)" or "1: Stopping on error (ErrorStop)" before the processing is completed after executing MC\_SetPosition (Current Position Change) with Execution mode (ExecutionMode) set to "1: Execute at completion (mcQueued)", MC\_SetPosition Instruction Error (error code: 1B9CH) occurs.
- When an error occurs in MC\_SetPosition (Current Position Change), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

### ■Target position (Position)

The values that can be set in Target position (Position) differ depending on whether Relative position selection (Relative) is TRUE or FALSE.

Set Target position (Position) within the following setting range.

However, even when the position is within the specified range, an error occurs and the operation is not executed if the set position is outside the software stroke limit range after the current position change.

| Relative position selection (Relative)                 | Target position (Position) setting range                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE (Current position change with absolute position) | <p>■When the ring counter is disabled<br/> <math>-10000000000.0 \leq \text{Setting value} &lt; 10000000000.0</math></p> <p>■When the ring counter is enabled<br/> <math>\text{Ring counter lower limit value} \leq \text{Setting value} &lt; \text{Ring counter upper limit value}</math></p>                                                                                              |
| TRUE (Current position change with relative distance)  | <p>■When the ring counter is disabled<br/> <math>-10000000000.0 \leq \text{Setting value} \leq 10000000000.0</math></p> <p>■When the ring counter is enabled<br/> <math>-(\text{Ring counter upper limit value} - \text{ring counter lower limit value}) / 2 \leq \text{Setting value} \leq (\text{Ring counter upper limit value} - \text{ring counter lower limit value}) / 2</math></p> |

## ■ Execution mode (ExecutionMode)

When MC\_SetPosition (Current Position Change) is executed during axis operation, the timing for the change depends on the setting of Execution mode (ExecutionMode). The timing for Execution mode (ExecutionMode) is shown below.

| Setting value                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

■Options (Options)

The function options for MC\_SetPosition (Current Position Change) are set in the specified bit position.  
The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name                           | Description                                                                                                                                                                          |
|-----|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Cancel accepted after FB start | Sets whether or not to allow a cancel after MC_SetPosition (Current Position Change) is executed. <ul style="list-style-type: none"><li>• 0: Disabled</li><li>• 1: Enabled</li></ul> |

■Operation overview

When MC\_SetPosition (Current Position Change) is executed while the axis is stopped, the current position change operation starts at rising edge detection of Execution command (Execute). In the current position change, the set position and the cumulative current position are changed to the position set in Target position (Position). Target position (Position) becomes "Current position change with relative distance" when Relative position selection (Relative) is TRUE and "Current position change with absolute position" when Relative position selection (Relative) is FALSE.

Ex.

When executing the current position change to "90.0" at a stop with a ring counter lower limit value of "0.0", a ring counter upper limit value of "360.0", and a set position of "180.0" (a cumulative current position of "540.0").

<When Relative position selection (Relative) is FALSE (absolute position)>

<When Relative position selection (Relative) is TRUE (relative distance)>

## ■Cancel

A current position change that is in the standby status can be canceled after MC\_SetPosition (Current Position Change) execution.

- To enable cancel, execute MC\_SetPosition (Current Position Change) with the status of "Cancel accepted after FB start (Options (Options): Bit 16)" set to "1: Allow".
- Cancel is started at falling edge detection of Execution command (Execute).
- Cancel is accepted only when Executing (Busy) of the output pin is TRUE.
- When MC\_SetPosition (Current Position Change) accepts the cancel, Cancel acceptance (CancelAccepted) of the output pin becomes TRUE.
- When cancel is completed, Abortion of execution (CommandAborted) of the output pin becomes TRUE.
- When cancelled, the set position is not changed.

### Ex.

After starting with Execution mode (ExecutionMode) set to "1: Execute at completion (mcQueued)", the change is cancelled while Axis Status (AxisName.Md.AxisStatus) is waiting to switch to "4: Standby (Standstill)"

## Precautions

Although the target position of the MC\_SetPosition (Current Position Change) being executed will not change if the current position is changed during axis operation, the operation to the target value will be changed because of the current position being changed.

## Program example

The following is a program example. The current position change command (bSetPosition) is set to TRUE, and the current position of Axis 1 (Axis0001) is changed to "100.0".

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name       | Data type                           | Comment                         |
|------------------|-------------------------------------|---------------------------------|
| MC_SetPosition_1 | MC_SetPosition                      | Current Position Change FB      |
| bSetPosition     | Bit                                 | Current position change command |
| lePosition       | Double-precision real number        | Target position                 |
| bDone            | Bit                                 | Ready                           |
| bBusy            | Bit                                 | Executing                       |
| bCommandAborted  | Bit                                 | Abortion of execution           |
| bError           | Bit                                 | Error                           |
| uwErrorID        | Word [unsigned]/bit string [16-bit] | Error code                      |
| bCancelAccepted  | Bit                                 | Cancel acceptance               |

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                   |
|-----------------|-----------------------|------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the torque limit value change is completed successfully.                                                                                                                                                      |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MCv_SetTorqueLimit (Torque Limit Value) is executed.                                                                                                                                                          |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MCv_SetTorqueLimit (Torque Limit Value) is aborted.                                                                                                                                              |
| CancelAccepted  | Cancel acceptance     | BOOL       | FALSE         | This variable becomes TRUE when MCv_SetTorqueLimit (Torque Limit Value) accepts the cancel.                                                                                                                                                   |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                              |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

- This FB changes a positive direction torque limit value or negative direction torque limit value.
- When Positive direction torque limit valid (PositiveValid) is TRUE, a positive direction torque limit value is changed to the value of Positive direction torque limit value (PositiveValue).
- When Negative direction torque limit valid (NegativeValid) is TRUE, a negative direction torque limit value is changed to the value of Negative direction torque limit value (NegativeValue).
- MCv\_SetTorqueLimit (Torque Limit Value) is executed when Execution command (Execute) is TRUE, and Executing (Busy) becomes TRUE when the processing starts normally.
- The timing for the torque limit change is set in Execution mode (ExecutionMode).
- When the processing is completed and the torque limit value is changed, Execution completion (Done) becomes TRUE.
- After starting MCv\_SetTorqueLimit (Torque Limit Value) with Execution mode (ExecutionMode) set to "1: Execute at completion (mcQueued)", if Axis status (AxisName.Md.AxisStatus) becomes "0: Axis disabled (Disabled)" or "1: Stopping on error (ErrorStop)" before the processing is completed, the processing is aborted and Abortion of execution (CommandAborted) becomes TRUE.
- When an error occurs in MCv\_SetTorqueLimit (Torque Limit Value), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- When Positive direction torque limit valid (PositiveValid) and Negative direction torque limit valid (NegativeValid) are both FALSE, the torque limit change is not performed and Execution completion (Done) becomes TRUE.

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ Execution mode (ExecutionMode)

When executing MCv\_SetTorqueLimit (Torque Limit Value) during axis operation, the timing of the change depends on the setting of Execution mode (ExecutionMode). The timing for Execution mode (ExecutionMode) is shown below.

| Setting value                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Execute immediately (mcImmediately)     | Executes immediately regardless of Axis status ( <u>AxisName</u> .Md.AxisStatus). Positive direction torque limit value ( <u>AxisName</u> .Cd.TorqueLimit_Positive) and Negative direction torque limit value ( <u>AxisName</u> .Cd.TorqueLimit_Negative) are changed at rising edge detection of Execution command (Execute).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3: Execute speculatively (mcSpeculatively) | <p>When Axis status (<u>AxisName</u>.Md.AxisStatus) of the relevant axis is "4: Standby (Standstill)" at rising edge detection of Execution command (Execute), the torque limit value change is executed.</p> <p>When Axis status (<u>AxisName</u>.Md.AxisStatus) of the relevant axis is not "4: Standby (Standstill)" or when an FB is being executed, MCv_SetTorqueLimit Instruction Error (error code: 1B9EH) occurs and the torque limit value change is not executed.</p> <p>The diagram illustrates the timing for Execution mode 3: mcSpeculatively. It shows the relationship between the Axis status (<u>AxisName</u>.Md.AxisStatus), the Execution mode (<u>AxisName</u>.Cd.ExecutionMode), the Execute command, the Busy signal, the Done signal, and the torque limit values (<u>AxisName</u>.Cd.TorqueLimit_Positive and <u>AxisName</u>.Cd.TorqueLimit_Negative). The Axis status is set to 4: Standstill. The Execution mode is set to 3: mcSpeculatively. The Execute command is triggered, and the Busy signal becomes active (low) after a delay. The Done signal becomes active (low) after a further delay. The torque limit values are updated at the rising edge of the Execute command, provided the axis is in Standby.</p> |

## ■ Options (Options)

The function options for MCv\_SetTorqueLimit (Torque Limit Value) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name                           | Description                                                                                                                                                                               |
|-----|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Cancel accepted after FB start | <p>Sets whether or not to allow a cancel after MCv_SetTorqueLimit (Torque Limit Value) is executed.</p> <ul style="list-style-type: none"> <li>0: Disabled</li> <li>1: Enabled</li> </ul> |

■Operation overview

- In MCv\_SetTorqueLimit (Torque Limit Value), Positive direction torque limit value (AxisName.Cd.TorqueLimit\_Positive) and Negative direction torque limit value (AxisName.Cd.TorqueLimit\_Negative) are changed.

- If Execution command (Execute) is set to TRUE while a value outside the range is set in Positive direction torque limit value (PositiveValue) or Negative direction torque limit value (NegativeValue), an error occurs in MCv\_SetTorqueLimit (Torque Limit Value) and Positive direction torque limit value (AxisName.Cd.TorqueLimit\_Positive) and Negative direction torque limit value (AxisName.Cd.TorqueLimit\_Negative) will not be changed.

## ■Cancel

A torque limit value change that is in the standby status can be canceled after MCv\_SetTorqueLimit (Torque Limit Value) execution.

- To enable cancel, execute MCv\_SetTorqueLimit (Torque Limit Value) with the status of "Cancel accepted after FB start (Options (Options): Bit 16)" set to "1: Allow".
- Cancel is started at falling edge detection of Execution command (Execute).
- Cancel is accepted only when Executing (Busy) of the output pin is TRUE.
- When MCv\_SetTorqueLimit (Torque Limit Value) accepts the cancel, Cancel acceptance (CancelAccepted) of the output pin becomes TRUE.
- When cancel is completed, Abortion of execution (CommandAborted) of the output pin becomes TRUE.
- When cancelled, Positive direction torque limit value (AxisName.Cd.TorqueLimit\_Positive) and Negative direction torque limit value (AxisName.Cd.TorqueLimit\_Negative) will not be changed.

### Ex.

After starting with Execution mode (ExecutionMode) set to "1: Execute at completion (mcQueued)", the change is cancelled while Axis Status (AxisName.Md.AxisStatus) is waiting to switch to "4: Standby (Standstill)"

## Precautions

In MCv\_SetTorqueLimit (Torque Limit Value), changing of Positive direction torque limit value (AxisName.Cd.TorqueLimit\_Positive) and Negative direction torque limit value (AxisName.Cd.TorqueLimit\_Negative) is performed.

## Program example

The following is a program example. The torque limit value change command (bSetTorqueLimit) is set to TRUE, and the positive direction torque limit value for Axis 1 (Axis0001) is changed to "100.0" and the negative direction torque limit value for Axis 1 (Axis0001) is changed to "200.0".

### Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### Labels used

| Label name           | Data type                           | Comment                               |
|----------------------|-------------------------------------|---------------------------------------|

# 45.6 Override Value Setting

## MC\_SetOverride

This FB changes the target velocity, the target acceleration, and the target deceleration of the specified axis.

| Ladder diagram | FBD/LD | ST                                                                                                                                                                                                                                          |

### Setting data

#### I/O variables

| I/O variable | Name             | Data type | Input    | Setting range | Default value         | Description                                                                                                                                                    |
|--------------|------------------|-----------|----------|---------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Axis         | Axis information | AXIS_REF  | At start | —             | Omission not possible | An axis is specified.<br>For the variable ( <u>AxisName</u> .AxisRef.) used, refer to the following.<br>Page 1444 <u>AxisName</u> .AxisRef. (Axis information) |

#### Input variable

| Input variable | Name                         | Data type | Input  | Setting range       | Default value | Description                                                                                                                                                                                                                          |
|----------------|------------------------------|-----------|--------|---------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable         | Enable                       | BOOL      | Always | TRUE, FALSE         | FALSE         | When this variable is set to TRUE, MC_SetOverride (Override Value Setting) is executed.                                                                                                                                              |
| VelFactor      | Velocity override factor     | LREAL     | Always | 0.00 to 10.00       | 0.00          | The velocity override factor is set.<br>When Enable (Enable) is TRUE, the value is always imported.                                                                                                                                  |
| AccFactor      | Acceleration override factor | LREAL     | Always | 0.00, 0.01 to 10.00 | 0.00          | The acceleration override factor is set.<br>When Enable (Enable) is TRUE, the value is always imported.<br>When "0.00" is set, the acceleration override factor is not changed and the control is performed with the previous value. |
| JerkFactor     | Jerk override factor         | LREAL     | Always | 0.0                 | 0.0           | "0.0" must be set.<br>* If a value other than "0.0" is set, Out of Jerk Override Coefficient (JerkFactor) Range (error code: 1BBEH) occurs.                                                                                          |

#### Output variables

| Output variable | Name       | Data type  | Default value | Description                                                                                                                                                 |
|-----------------|------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enabled         | Enabled    | BOOL       | FALSE         | This variable becomes TRUE when the override values are set correctly.                                                                                      |
| Busy            | Executing  | BOOL       | FALSE         | This variable becomes TRUE when MC_SetOverride (Override Value Setting) is executed.                                                                        |
| Error           | Error      | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- This FB changes the target velocity, the target acceleration, and the target deceleration of the specified axis.
- The current operating target velocity, target acceleration, and target deceleration values are changed by multiplying each value by the override factor.
- MC\_SetOverride (Override Value Setting) is executed when Enable (Enable) becomes TRUE. Enabled (Enabled) becomes TRUE while the override factor is valid.
- If the override factor value is changed while Enable (Enable) is TRUE, the new override factor is reflected.
- When an error occurs in MC\_SetOverride (Override Value Setting), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- When the value for Velocity override factor (VelFactor) is set to "0.00", the axis stops without Axis status (AxisName.Md.AxisStatus) changing to "4: Standby (Standstill)".
- When the value for Acceleration override factor (AccFactor) is set to "0.00", the acceleration override factor is not changed and the previous acceleration override factor is maintained.

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1435 Basic operation of Enable (Enable) type motion control FBs

## ■ Operation overview

- In MC\_SetOverride (Override Value Setting), Velocity override factor (AxisName.Cd.VelocityOverride) and Acceleration override factor (AxisName.Cd.AccelerationOverride) are changed.

- If a value outside the range is set as the override factor, an error occurs in MC\_SetOverride (Override Value Setting) and subsequent values will not be imported. To import values again, restart Enable (Enable).

## Precautions

- Do not arrange two or more MC\_SetOverride (Override Value Setting) in the same axis. The operation is not guaranteed if two or more of this FB are set.
- In single axis control, only the override factor set with the axis control data has an effect.
- Do not operate Velocity override factor (AxisName.Cd.VelocityOverride) or Acceleration override factor (AxisName.Cd.AccelerationOverride) directly while executing MC\_SetOverride (Override Value Setting).
- When the speed after Speed override is out of range, refer to "Velocity Range" in the following.

User's manual for the controller used

- When the acceleration, deceleration, acceleration time, and deceleration time after acceleration override is out of range, refer to "Acceleration/deceleration processing function" in the following.

User's manual for the controller used

## Program example

The following is a program example. The override value change command (bSetOverride) is set to TRUE, and the target velocity, target acceleration, and target deceleration of Axis 1 (Axis0001) are changed to values multiplied by a velocity override factor of "1.0" and an acceleration/deceleration override factor of "2.0".

### Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### Labels used

| Label name       | Data type                           | Comment                                   |

| SDOStatus       | SDO transfer status     | WORD(UINT) | 0             | This variable stores the processing status of the transient request.<br>For details, refer to the following.<br> Page 1564 SDO transfer status (SDOStatus)   |
| ReadCounter     | Number of reading times | WORD(UINT) | 0             | This variable stores the number of parameter reading times.<br>When "0" is set to Number of reading times (ReadCount), the variable works as a ring counter of "0 to 65535".                                                                  |

## Processing details

- This FB reads object data by setting a value 00010000H or greater in Parameter No. (ParameterNumber). In this case, the object data is sent/received using the transient transmission function.
- When a transient request error (response code (SDO Abort Code)) is received from the device, Error (Error) becomes TRUE, SDO Communication Error (error code: 1A48H) is stored in Error code (ErrorID), and the response code (SDO Abort Code) from the device is stored in Transient error code (SDOErrorID).

## Timing chart

- When the processing is completed successfully

Reading is performed for the number of times set in the number of reads (ReadCount) until Enable becomes FALSE.  
(When the number of reads (ReadCount) is "0", reading is continuously performed until Enable becomes FALSE.)

- When the processing is completed with an error

- SDO communication error

- I/O variable or input variable error

## ■Parameter No. (ParameterNumber)

- The classification of Parameter No. (ParameterNumber) set when reading parameters is shown below.

| Parameter No.          | Description                       |
|------------------------|-----------------------------------|
| 00010000H to FFFFFFFFH | The object of the device station. |

- The contents of Parameter No. (ParameterNumber) when setting the object of the device station are shown below.

- When setting the size of the objects of the device station, specify 1 byte (08H)/ 2 bytes (10H)/ 4 bytes (20H)/ 8 bytes (40H) in bits. If "00H" is specified, the parameter read is performed with default size. If a value other than the above setting values is specified, Out of Parameter No. Range (error code: 1BC2H) occurs.
- When the size specified with Parameter No. (ParameterNumber) differs from default size of the object data, the operations depend on the specifications of the drive unit.

### Ex.

When setting object index "6099H", UNSIGNED32 object of subindex "02H", and a size of "00H".  
Set "60990200H".

### Point

For the objects of each device station, refer to the device station manual.

## ■Options (Options)

The function options for MC\_ReadParameter (Parameter Read) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name               | Description                                                                                                      |
|-----|--------------------|------------------------------------------------------------------------------------------------------------------|
| 16  | Specifies unsigned | Sets whether to store the read value of the integer data with or without a sign.<br>• 0: Signed<br>• 1: Unsigned |

## ■SDO transfer status (SDOStatus)

This variable stores the processing status of the transient request.

| Bit    | Name                                  | Description                                                                                                                  |
|--------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 0 to 7 | Response object size (byte)           | Stores the object size sent by the device stations when the processing is completed.                                         |
| 8      | The transient transmission acceptance | Stores the transient transmission status.<br>• 0: Unexecuted transient transmission<br>• 1: Accepting transient transmission |
| 10     | Issuing SLMP                          | Stores the SLMP status.<br>• 0: Unexecuted SLMP<br>• 1: Issuing SLMP                                                         |

## Precautions

- Up to four transient transmissions can be executed toward the same axis. If MC\_ReadParameter (Parameter Read) is executed for object data towards an axis which is already executing four transient transmissions, Parameter Reading And Writing FB Execution Disabled Error (error code: 1BC1H) occurs and the next FB is not executed. However, the FB being executed continues.
- For the driver homing method, home position data of the drive unit is obtained using the transient transmission function. Therefore, if a parameter read for object data is executed when MC\_Home (OPR) is being executed, ABS Reference Point Read Error (error code: 1AF9H) may occur in MC\_Home (OPR).
- When reading the integer type/BOOL type parameters or object data, the value read with MC\_ReadParameter (Parameter Read) is converted into an LREAL type or BOOL type and output.

### Ex.

Reading parameters while specifying two bytes size in MC\_ReadParameter (Parameter Read).

| Parameter value | Read value (Value) (Data type: LREAL)                         |                                                                 |
|-----------------|---------------------------------------------------------------|-----------------------------------------------------------------|
|                 | Specifies unsigned (Options (Options): Bit 16)<br>"0: Signed" | Specifies unsigned (Options (Options): Bit 16)<br>"1: Unsigned" |
| 10000           | 10000.0                                                       | 10000.0                                                         |
| -20000          | -20000.0                                                      | 45536.0                                                         |
| 65535           | -1.0                                                          | 65535.0                                                         |
| 63356           | 0.0                                                           | 0.0                                                             |
| 131701          | -1.0                                                          | 65535.0                                                         |

- Values changed with MC\_ReadParameter (Parameter Read) are not saved. To use the changed values at the next power supply, save the parameters.  
For how to save parameters of objects of device stations, refer to the manual for the device stations.
- When devices in transient transmission are disconnected, all the transient requests for disconnected devices fail, and SDO Communication Error (error code: 1A48H) occurs.
- Before executing MC\_ReadParameter (Parameter Read), ensure that Driver status (AxisName.Md.Driver\_State) is not set to "-1: Axis variable not initialized/axis parameter error (Invalid)" or "0: Not Ready To Switch On (NotReadyToSwitchOn)". If executed in a status other than the above, Parameter Reading And Writing FB Execution Disabled Error (error code: 1BC1H) will occur.

## Program example

The following is a program example. The parameter read command (bReadParameter) is set to TRUE, and the values in the objects (index "6099H", subindex "02H", and size "00H") of Axis1 (Axis0001) are read.

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name         | Data type                                                | Comment                 |
|--------------------|----------------------------------------------------------|-------------------------|
| MC_ReadParameter_1 | MC_ReadParameter                                         | Parameter Read FB       |
| bReadParameter     | Bit                                                      | Program read command    |
| dwParameterNumber  | Double word [unsigned]/bit string [32-bit] (hexadecimal) | Parameter No.           |
| uwReadCount        | Word [unsigned]/bit string [16-bit]                      | Number of reading times |
| bValid             | Bit                                                      | Output value valid      |
| bBusy              | Bit                                                      | Executing               |
| bError             | Bit                                                      | Error                   |
| uwErrorID          | Word [unsigned]/bit string [16-bit]                      | Error code              |
| dwSDOErrorID       | Double word [unsigned]/bit string [32-bit] (hexadecimal) | Transient error code    |
| leValue            | Double-precision real number                             | Read value              |
| uwSDOStatus        | Word [unsigned]/bit string [16-bit]                      | SDO transfer status     |
| uwReadCounter      | Word [unsigned]/bit string [16-bit]                      | Number of reading times |

### Setting data

#### I/O variables

| I/O variable | Name             | Data type | Input    | Setting range | Default value         | Description                                                                                                                                                    |
|--------------|------------------|-----------|----------|---------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Axis         | Axis information | AXIS_REF  | At start | —             | Omission not possible | An axis is specified.<br>For the variable ( <u>AxisName</u> .AxisRef.) used, refer to the following.<br>Page 1444 <u>AxisName</u> .AxisRef. (Axis information) |

#### Input variable

| Input variable  | Name              | Data type               | Input    | Setting range          | Default value | Description                                                                                                                                                                                                              |
|-----------------|-------------------|-------------------------|----------|------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Execute         | Execution command | BOOL                    | At start | TRUE, FALSE            | FALSE         | When this variable is set to TRUE, MC_WriteParameter (Parameter Write) is executed.                                                                                                                                      |
| ParameterNumber | Parameter No.     | DWORD(HEX)              | At start | 00010000H to FFFFFFFFH | 00000000H     | The object of a device station is set.<br>For details, refer to the following.<br>Page 1570 Parameter No. (ParameterNumber)                                                                                              |
| Value           | Setting value     | LREAL                   | At start | —                      | 0.0           | The setting value of the set parameter is set.                                                                                                                                                                           |
| ExecutionMode   | Execution mode    | INT (MC_EXECUTION_MODE) | At start | 0, 1                   | 0             | The writing method of the set parameter is set.<br>• 0: Execute immediately (mcImmediately)<br>• 1: Execute at completion (mcQueued)<br>For details, refer to the following.<br>Page 1571 Execution mode (ExecutionMode) |
| Options         | Options           | DWORD(HEX)              | At start | 00000000H to 00010000H | 00000000H     | The function options for MC_WriteParameter (Parameter Write) are set in the specified bit position.<br>For details, refer to the following.<br>Page 1571 Options (Options)                                               |

## Output variables

| Output variable | Name                 | Data type  | Default value | Description                                                                                                                                                                                                                                   |
|-----------------|----------------------|------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion | BOOL       | FALSE         | This variable becomes TRUE when the parameter writing is completed.                                                                                                                                                                           |
| Busy            | Executing            | BOOL       | FALSE         | This variable becomes TRUE when MC_WriteParameter (Parameter Write) is executed.                                                                                                                                                              |
| Error           | Error                | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                              |
| ErrorID         | Error code           | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |
| SDOErrorID      | Transient error code | DWORD(HEX) | 00000000H     | When an error occurs in SDO communication, this variable returns the response code (SDO Abort Code).                                                                                                                                          |
| SDOStatus       | SDO transfer status  | WORD(UINT) | 0             | This variable stores the processing status of the transient request.<br>For details, refer to the following.<br> Page 1571 SDO transfer status (SDOStatus)   |

## Processing details

- This FB writes object data by setting a value 00010000H or greater in Parameter No. (ParameterNumber). In this case, the object data is sent/received using the transient transmission function.
- When a transient request error (response code (SDO Abort Code)) is received from the device, Error (Error) becomes TRUE, SDO Communication Error (error code: 1A48H) is stored in Error code (ErrorID), and the response code (SDO Abort Code) from the device is stored in Transient error code (SDOErrorID).

## Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

- SDO communication error

- I/O variable or input variable error

## Parameter No. (ParameterNumber)

- The classification of Parameter No. (ParameterNumber) set when writing parameters is shown below.

| Parameter No.          | Description                       |
|------------------------|-----------------------------------|
| 00010000H to FFFFFFFFH | The object of the device station. |

- The contents of Parameter No. (ParameterNumber) when setting the object of the device station are shown below.

- When setting the size of the objects of the device station, specify 1 byte (08H)/ 2 bytes (10H)/ 4 bytes (20H)/ 8 bytes (40H) in bits. If "00H" is specified, the parameter write is performed at 4 bytes. If a value other than the above setting values is specified, Out of Parameter No. Range (error code: 1BC2H) occurs.
- When the size specified with Parameter No. (ParameterNumber) differs from default size of the object data, the operations depend on the specifications of the drive unit.

### Ex.

When setting object index "6099H", UNSIGNED32 object of subindex "02H", and a size of "00H".  
Set "60990200H".

## ■Execution mode (ExecutionMode)

When executing a parameter write, set the timing of the write in Execution mode (ExecutionMode).

| Setting value                          | Description                                                                                                                                               |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Execute immediately (mcImmediately) | The write is executed immediately.<br>The axis operations might be affected because the reflection timing depends on each parameter.                      |
| 1: Execute at completion (mcQueued)    | The write is executed after the axis stops (Axis status ( <u>AxisName</u> .Md.AxisStatus) is "0: Axis disabled (Disabled)" or "4: Standby (Standstill)"). |

## ■Options (Options)

The function options for MC\_WriteParameter (Parameter Write) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name               | Description                                                                                                      |
|-----|--------------------|------------------------------------------------------------------------------------------------------------------|
| 16  | Specifies unsigned | Sets whether to store the read value of the integer data with or without a sign.<br>• 0: Signed<br>• 1: Unsigned |

## ■SDO transfer status (SDOStatus)

This variable stores the processing status of the transient request.

| Bit    | Name                                  | Description                                                                                                                  |
|--------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 0 to 7 | Response object size (byte)           | Stores the object size sent by the device stations when the processing is completed.                                         |
| 8      | The transient transmission acceptance | Stores the transient transmission status.<br>• 0: Unexecuted transient transmission<br>• 1: Accepting transient transmission |
| 10     | Issuing SLMP                          | Stores the SLMP status.<br>• 0: Unexecuted SLMP<br>• 1: Issuing SLMP                                                         |

## Precautions

- Up to four transient transmissions can be executed toward the same axis. If MC\_WriteParameter (Parameter Write) is executed for object data towards an axis which is already executing four transient transmissions, Parameter Reading And Writing FB Execution Disabled Error (error code: 1BC1H) occurs and the next FB is not executed. (The FB being executed continues.)
- For the driver homing method, home position data of the drive unit is obtained using the transient transmission function. Therefore, if a parameter write for object data is executed when MC\_Home (OPR) is being executed, ABS Reference Point Read Error (error code: 1AF9H) may occur in MC\_Home (OPR).
- When writing the integer type/BOOL type parameters or object data, the setting value of MC\_WriteParameter (Parameter Write) is converted into an integer type or BOOL type and imported.

### Ex.

Writing parameters while specifying two bytes size in MC\_WriteParameter (Parameter Write).

| Setting value (Value)<br>(Data type: LREAL) | Write value (2 bytes data)                                    |                                                                 |
|---------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------------|
|                                             | Specifies unsigned (Options (Options): Bit 16)<br>"0: Signed" | Specifies unsigned (Options (Options): Bit 16)<br>"1: Unsigned" |
| 10000.5                                     | 10000                                                         | 10000                                                           |
| -10000.4                                    | -10000                                                        | 55536                                                           |
| 65535.0                                     | -1                                                            | 65535                                                           |
| -65535.0                                    | 1                                                             | 1                                                               |
| 63356.0                                     | 0                                                             | 0                                                               |
| 131701.0                                    | -1                                                            | 65535                                                           |

- Values changed with MC\_WriteParameter (Parameter Write) are not saved. To use the changed values at the next power supply, save the parameters.  
For how to save parameters of objects of device stations, refer to the manual for the device stations.
- When devices in transient transmission are disconnected, all the transient requests for disconnected devices fail, and SDO Communication Error (error code: 1A48H) occurs.
- Before executing MC\_WriteParameter (Parameter Write), ensure that Driver status (AxisName.Md.Driver\_State) is not set to "-1: Axis variable not initialized/axis parameter error (Invalid)" or "0: Not Ready To Switch On (NotReadyToSwitchOn)". If executed in a status other than the above, Parameter Reading And Writing FB Execution Disabled Error (error code: 1BC1H) will occur.

## Program example

The following is a program example. The parameter write command (bWriteParameter) is set to TRUE, and "100.0" is written to the objects (index "6099H", subindex "02H", and size "00H") of Axis1 (Axis0001).

### Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### Labels used

| Label name          | Data type                                                | Comment                 |
|---------------------|----------------------------------------------------------|-------------------------|
| MC_WriteParameter_1 | MC_WriteParameter                                        | Parameter Write FB      |
| bWriteParameter     | Bit                                                      | Parameter write command |
| dwParameterNumber   | Double word [unsigned]/bit string [32-bit] (hexadecimal) | Parameter No.           |
| leValue             | Double-precision real number                             | Setting value           |
| bDone               | Bit                                                      | Execution completion    |
| bBusy               | Bit                                                      | Executing               |
| bError              | Bit                                                      | Error                   |
| uwErrorID           | Word [unsigned]/bit string [16-bit]                      | Error code              |

### Input variable

| Input variable | Name              | Data type  | Input    | Setting range | Default value | Description                                                                                                      |
|----------------|-------------------|------------|----------|---------------|---------------|------------------------------------------------------------------------------------------------------------------|
| Execute        | Execution command | BOOL       | At start | TRUE, FALSE   | FALSE         | When this variable is set to TRUE, MC_Reset (Axis Error Reset) is executed.                                      |
| Options        | Options           | DWORD(HEX) | At start | 0000000H      | 0000000H      | Set "00000000H".<br>* If a value other than "00000000H" is set, Out of Options Range (error code: 1BC3H) occurs. |

### Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                    |
|-----------------|-----------------------|------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the error reset is completed.                                                                                                                  |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MC_Reset (Axis Error Reset) is executed.                                                                                                       |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when MC_Reset (Axis Error Reset) has been aborted because of timeout.<br>The variable becomes FALSE when Execution command (Execute) becomes FALSE. |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                               |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used                    |

## Processing details

- This FB is executed when Execution command (Execute) is set to TRUE. When the processing starts, Executing (Busy) becomes TRUE and Axis error reset (AxisName.Cd.ErrorReset) of the target axis also becomes TRUE.
- Executing (Busy) becomes FALSE and Execution completion (Done) becomes TRUE when clearing of the errors and warnings is completed.
- If executed when Axis status (AxisName.Md.AxisStatus) is other than "1: Stopping on error (ErrorStop)", Executing (Busy) becomes FALSE and Execution completion (Done) becomes TRUE after the warnings are cleared.
- Errors and warnings are not cleared if Execution command (Execute) is set to TRUE while the error and warning causes still remain. If the error is not cleared within one second after the instruction is executed, Abortion of execution (CommandAborted) becomes TRUE. Turn Execution command (Execute) to FALSE temporarily and clear the error and warning causes, then set Execution command (Execute) to TRUE again.
- When an error occurs in MC\_Reset (Axis Error Reset), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

📖 User's manual for the controller used

### ■ Timing chart

- When the processing is completed successfully

- At timeout

## Precautions

Do not operate Axis error reset (AxisName.Cd.ErrorReset) directly while executing MC\_Reset (Axis Error Reset).

## Program example

The following is a program example. The error reset command (bErrorReset) is set to TRUE, and errors and warnings of Axis 1 (Axis0001) are reset.

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name      | Data type                           | Comment               |
|-----------------|-------------------------------------|-----------------------|
| MC_Reset_1      | MC_Reset                            | Axis Error Reset FB   |
| bErrorReset     | Bit                                 | Error reset command   |
| bDone           | Bit                                 | Execution completion  |
| bBusy           | Bit                                 | Executing             |
| bCommandAborted | Bit                                 | Abortion of execution |
| bError          | Bit                                 | Error                 |
| uwErrorID       | Word [unsigned]/bit string [16-bit] | Error code            |

## Processing details

- This FB is executed at the rising edge of Execution command (Execute). When the processing starts, Executing (Busy) becomes TRUE and Axes group error reset (AxesGroupName.Cd.ErrorReset) of the target axes group also becomes TRUE.
- Executing (Busy) becomes FALSE and Execution completion (Done) becomes TRUE when clearing of the errors and warnings is completed for the axes group or individual axis.
- If executed when Axes group status (AxesGroupName.Md.GroupStatus) is other than "1: Stopping on error (GroupErrorStop)", Executing (Busy) becomes FALSE and Execution completion (Done) becomes TRUE after the warnings are cleared.
- Axis errors and warnings are not cleared if Execution command (Execute) is set to TRUE while the error and warning causes still remain. In this case, if the errors are not cleared within one second after the FB is executed, Abortion of execution (CommandAborted) becomes TRUE and Axes group error reset (AxesGroupName.Cd.ErrorReset) of the target axes group becomes FALSE. Set Execution command (Execute) to FALSE temporarily and clear the error and warning causes, then set Execution command (Execute) to TRUE again.
- When an error occurs in MC\_GroupReset (Axes Group Error Reset), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

### ■Timing chart

- When the processing is completed successfully

- At timeout

## Precautions

Do not operate Axes group error reset (AxesGroupName.Cd.ErrorReset) directly while executing MC\_GroupReset (Axes Group Error Reset).

## Program example

The following is a program example. The axes group error reset command (bGroupErrorReset) is set to TRUE, and errors and warnings of Axes group 1 (AxesGroup001) are reset.

### ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

### ■Labels used

| Label name       | Data type                           | Comment                        |
|------------------|-------------------------------------|--------------------------------|
| MC_GroupReset_1  | MC_GroupReset                       | Axes Group Error Reset FB      |
| bGroupErrorReset | Bit                                 | Axes group error reset command |
| bDone            | Bit                                 | Execution completion           |
| bBusy            | Bit                                 | Executing                      |
| bCommandAborted  | Bit                                 | Abortion of execution          |
| bError           | Bit                                 | Error                          |
| uwErrorID        | Word [unsigned]/bit string [16-bit] | Error code                     |

### ■FBD/LD program

### ■ST program

```

MC_GroupReset_1(
  AxesGroup:= AxesGroup001.AxesGroupRef ,
  Execute:= bGroupErrorReset ,
  Options:= H00000000 ,
  Done=> bDone ,
  Busy=> bBusy ,
  CommandAborted=> bCommandAborted ,
  Error=> bError ,
  ErrorID=> uwErrorID
);

```

# 45.11 Touch Probe Enabled

45

## MC\_TouchProbe

This FB records optional data when a trigger event occurs.

| Ladder diagram                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | FBD/LD                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## ■ Output variables

| Output variable  | Name                       | Data type  | Default value | Description                                                                                                                                                                                                                                     |
|------------------|----------------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done             | Completion                 | BOOL       | FALSE         | This variable becomes TRUE when the control is completed.                                                                                                                                                                                       |
| Busy             | Executing                  | BOOL       | FALSE         | This variable becomes TRUE when MC_TouchProbe (Touch Probe Enabled) is executed.                                                                                                                                                                |
| CommandAborted   | Abortion of execution      | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_TouchProbe (Touch Probe Enabled) is aborted because of an error or multiple start.                                                                                                              |
| Error            | Error                      | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                |
| ErrorID          | Error code                 | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |
| PositionData     | Current value monitor data | LREAL      | 0.0           | The current value of the latch target data is stored.                                                                                                                                                                                           |
| RecordedPosition | Latch position             | LREAL      | 0.0           | The current value when a trigger event occurred is set.<br>When latch is executed multiple times, the data is overwritten by the latest data.                                                                                                   |
| RecordedCounter  | Number of latch times      | WORD(UINT) | 0             | The number of latch times is stored.                                                                                                                                                                                                            |
| TouchProbeID     | Probe ID                   | WORD(UINT) | 0             | An ID unique to MC_TouchProbe (Touch Probe Enabled) is stored.                                                                                                                                                                                  |

## Processing details

- This FB estimates and calculates the latch data on the rising edge/falling edge/both directions of the signal specified in Trigger input signal (TriggerInput).
- When Enabled window (WindowOnly) is TRUE, checks whether the latch data at trigger event occurrence is within the range of Lower limit position (FirstPosition) and Upper limit position (LastPosition) or not. Data outside the range are not latched.
- The latch data is stored to the storage location set in Latch position (RecordedPosition) or Storage location of latch data (OutputBuffer) according to Latch mode (RecordMode), and Number of latch times (RecordedCounter) is updated.
- The probe data during operation cycle interval is calculated by estimation. The value calculated by estimation when Trigger input signal (TriggerInput) is input is the latch data. The value is calculated as shown in the figure below.

■ When the probe data is WORD type

- When using an external signal high-accuracy input

The trigger input timing is the time when the device station detects the signal.

- \* For setting method of high-accuracy input of the external signal selection, refer to the following.

📖 User's manual for the controller used

- \* For the accuracy of signal detection time, refer to the manuals for the device used.

- When not using an external signal high-accuracy input

The trigger input timing is the operation cycle.

## ■Timing chart

- When the processing is completed successfully
- When Latch mode (RecordMode) is "0: One shot mode (OneShot)"

- When Latch mode (RecordMode) is "1: Frequency specified mode (RecordCount)"
- When Number of latch times (RecordCount) is two

- When Latch mode (RecordMode) is "2: Ring buffer mode (RingBuffer)"

When Number of latch times (RecordCount) is two

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Trigger input signal (TriggerInput)

Trigger input signal is set in the MC\_TRIGGER\_REF structure. For the MC\_TRIGGER\_REF structure, refer to the following.

📖 Page 1487 MC\_TRIGGER\_REF

The setting range for Trigger input signal (Signal) of the MC\_TRIGGER\_REF structure set in Trigger input signal (TriggerInput) is shown below.

The type for Trigger signal (Signal) is SIGNAL\_SELECT structure. For the SIGNAL\_SELECT structure, refer to the following.

📖 Page 1492 SIGNAL\_SELECT (Signal select)

|                               | FilterTime (Filter time)             | LREAL                                                      | 0.0 to 5.0 [s]                                                                                                                                                                                                                                   |

\*1 When the target modification is omitted, the object of Axis Information (Axis) axis is referred to. However, if the Axis Information (Axis) axis does not have a station address, or if a station address has not been set, External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H) occurs. When the station address for the target modification has been specified, the Axis Information (Axis) is ignored.

When the referred station has the Axis Emulate function enabled and also has a set station address, the emulating object will be referred to.

To use external signal high-accuracy input, set Detection (Signal detection method) to 4: Detection at rising edge/falling edge (BothEdges).

\*2 External signal high-accuracy input can be used. For details, refer to the following.

📖 User's manual for the controller used

When a signal that cannot be used for Signal name (TriggerInput.Signal.Source.Target) is used, one of the following errors will be output: External signal selection string incorrect (error code: 1B05H), External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H), or Add-on Signal IO internal error (error code: 1B33H or 1BD8H).

### Point

When using an external signal high-accuracy input, set the Filter time (TriggerInput.Signal.FilterTime) to "0". If set to a value other than "0", the signal detection time will not be correctly obtained. If the device station has an input filter, use this device station filter. If the device station does not have an input filter, use the Window enabled (WindowOnly), Lower limit position (FirstPosition), and Upper limit position (LastPosition) of Touch Probe Enabled (MC\_TouchProbe) together to prevent a false detection of the trigger signal due to noise.

■ **Enabled window (WindowOnly)/Lower limit position (FirstPosition)/Upper limit position (LastPosition)**

When Enabled window (WindowOnly) is valid (TRUE), triggers are detected only within the range between Lower limit position (FirstPosition) and Upper limit position (LastPosition) of the probe data. When it is invalid (FALSE), the touch probe processing is executed for the entire range.

| Lower limit position (FirstPosition)/Upper limit position (LastPosition) relation | Touch probe processing                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lower limit position (FirstPosition) ≤ Upper limit position (LastPosition)        | <p>The touch probe processing is executed when the probe data is more than Lower limit position (FirstPosition) and less than Upper limit position (LastPosition).</p>  |
| Lower limit position (FirstPosition) > Upper limit position (LastPosition)        | <p>The touch probe processing is executed when the probe data is less than Upper limit position (LastPosition) or more than Lower limit position (FirstPosition).</p>   |

## ■Probe data (ProbeData)

Set the data to latch in the TARGET\_REF structure. For the TARGET\_REF structure, refer to the following.

📖 Page 1489 TARGET\_REF (Input signal)

The settable data categories are shown below.

| Data classification                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| [OBJ]               | When [VAR] is set to a Word type label. <ul style="list-style-type: none"> <li>Ring counter upper limit value: 65535</li> <li>Ring counter lower limit value: 0</li> </ul>                                                                                                                                                                                                                                                                                                      |

### Restriction

Ensure that the change amount per operation cycle satisfies the following formula. Failing to do so may cause the actual change amount of the probe data and the latched change amount to not match.

$$\text{Variation amount of one operation cycle} < \frac{|\text{(ring counter maximum value)} - \text{(ring counter minimum value)}| + 1}{2}$$

## ■ Compensation time (CompensationTime)

Compensates for the delay time of the touch probe processing. Set this variable to compensate for delays specific to the touch probe processing separately from the compensation time of the trigger input signal. To compensate for delays, set a positive number. To compensate for the progression, set a negative number.

The total compensation time = Compensation time (CompensationTime) - Compensation time (TriggerInput.Signal.CompensationTime)

### Point

When compensating for the delay time, the past value is used for latch data estimate calculation. As such, the maximum accuracy is reached when the compensation time is passed after Executing (Busy) becomes TRUE. In addition, memory is consumed as shown below depending on the compensation time and the operation cycle.

- Memory consumption = 24 bytes × (total compensation time ÷ operation cycle)

- When compensating for delays (when the total compensation time is a positive number)

The estimate is calculated based on the operation cycle data after latching and before the compensation time is passed.

- When compensating for the progression (when the total compensation time is a negative number)

The estimate is calculated based on the operation cycle data at latching.

## ■Latch mode (RecordMode)

Sets the latch method for the data. The latch methods are shown below.

| Setting value                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 0: One shot mode (OneShot)                | Becomes "1" at latch operation.                                                                                         | Stores latch data one time only.                      |
| 1: Frequency specified mode (RecordCount) | Adds "+1" at each latch operation.                                                                                      | Stores the latest latch data at each latch operation. |
| 2: Ring buffer mode (RingBuffer)          | Adds "+1" at each latch operation.<br>Returns to "0" when the value of Number of latch times (RecordCount) is exceeded. | Stores the latest latch data at each latch operation. |

## ■Number of latch times (RecordCount)

Based on the setting of Latch mode (RecordMode), the following values are stored in Number of latch times (RecordCount).

| Latch mode (RecordMode)                   | Number of latch times (RecordCount)                                                                                               |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 0: One shot mode (OneShot)                | Ignored.                                                                                                                          |
| 1: Frequency specified mode (RecordCount) | The number of latch times is set. When the setting is out of range, Latch Count Incorrect (error code: 1B8AH) occurs.             |
| 2: Ring buffer mode (RingBuffer)          | Sets the number of times for the ring buffer. When the setting is out of range, Latch Count Incorrect (error code: 1B8AH) occurs. |

## ■Storage location of latch data (OutputBuffer)

Set the storage location of the latched data in the TARGET\_REF structure. For the TARGET\_REF structure, refer to the following.

📖 Page 1489 TARGET\_REF (Input signal)

- The usable data classifications are [VAR] and [DEV].
- As latched data will be stored as LREAL type, when setting non-LREAL type data in Target (Target) of the TARGET\_REF structure, set "(LREAL)" explicitly to the data type.
- The storage location of the latched data is shown below.

| Latch mode (RecordMode)                   | Storage location                                                                                                                              |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 0: One shot mode (OneShot)                | The area specified in Storage location of latch data (OutputBuffer).                                                                          |
| 1: Frequency specified mode (RecordCount) | Following area<br>Area specified in Storage location of latch data (OutputBuffer) + Number of latch times (RecordedCounter) × latch data size |
| 2: Ring buffer mode (RingBuffer)          |                                                                                                                                               |

- Storage location of latch data (OutputBuffer) can be omitted. When omitted, the latch data is only stored in Latch position (RecordedPosition).
- A setting example in which Storage location of latch data (OutputBuffer) is set in Target (Target) of the TARGET\_REF structure is shown below.

**Ex.**

When the following settings are used

| Example | Description                                                                                                                                                                                                                                                                                     | Setting                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | <ul style="list-style-type: none"> <li>• When Latch mode (RecordMode) is "0: One shot mode (OneShot)"</li> <li>• When Number of latch times (RecordCount) is "1" while Latch mode (RecordMode) is "1: Frequency specified mode (RecordCount)" or "2: Ring buffer mode (RingBuffer)".</li> </ul> | <ul style="list-style-type: none"> <li>• [VAR]OutputBufferData1<sup>*1</sup></li> </ul>                                                       |
| 2       | <ul style="list-style-type: none"> <li>• When Number of latch times (RecordCount) is "100" while Latch mode (RecordMode) is "1: Frequency specified mode (RecordCount)" or "2: Ring buffer mode (RingBuffer)".</li> </ul>                                                                       | <ul style="list-style-type: none"> <li>• [VAR]OutputBufferData2<sup>*2</sup></li> <li>• [VAR](LREAL)OutputBufferData3<sup>*3</sup></li> </ul> |

\*1 "OutputBufferData1" is an LREAL type instance

\*2 "OutputBufferData2" is an LREAL[0..99] type instance

\*3 "OutputBufferData3" is a WORD[0..399] type instance

- When the number of elements set in Storage location of latch data (OutputBuffer) is less than the value of Number of latch times (RecordCount), Latch Data Storage Shortage (error code: 1BBFH) occurs. Latch Data Storage Shortage (error code: 1BBFH) also occurs when access outside the device or label range is made during latch operation.
- The relation between the setting value and operation of each item is shown below.

| Latch mode (RecordMode)                   | Number of latch times (RecordCount)                    | Storage location of latch data (OutputBuffer) | Detection operation | Data storage location                    |
|-------------------------------------------|--------------------------------------------------------|-----------------------------------------------|---------------------|------------------------------------------|
| 0: One shot mode (OneShot)                | Within the setting range/<br>outside the setting range | Omit                                          | One time            | Latch position (RecordedPosition)        |
|                                           |                                                        | Set                                           |                     | Latch position (RecordedPosition)/buffer |
| 1: Frequency specified mode (RecordCount) | Outside the setting range                              | Omit/Set                                      | Error               | —                                        |
|                                           |                                                        |                                               |                     |                                          |
|                                           | Within the setting range                               | Omit                                          | Setting number      | Latch position (RecordedPosition)        |
|                                           |                                                        | Set                                           |                     | Latch position (RecordedPosition)/buffer |
| 2: Ring buffer mode (RingBuffer)          | Outside the setting range                              | Omit/Set                                      | Error               | —                                        |
|                                           |                                                        |                                               |                     |                                          |
|                                           | Within the setting range                               | Omit                                          | Always              | Latch position (RecordedPosition)        |
|                                           |                                                        | Set                                           |                     | Latch position (RecordedPosition)/buffer |

## Precautions

- The touch probe is controlled (detection and latch of trigger input signals) in the following operation cycles, regardless of the FB call task (scan/fixed cycle/event). The detection cycle of trigger input signals differs depending on the data category set in TriggerInput.

| Category                             | Period                                    |
|--------------------------------------|-------------------------------------------|
| [VAR]                                | First operation cycle                     |
| [DEV]                                |                                           |
| [CONST]                              |                                           |
| [OBJ]                                | Communication cycle of the target station |
| [LINK]                               |                                           |
| [VAR] With a network label specified |                                           |

The data set in the probe data (ProbeData) is latched at the following cycles.

| Category                             | Period                                     |
|--------------------------------------|--------------------------------------------|
| [VAR]                                | First operation cycle                      |
| [DEV]                                |                                            |
| [OBJ]                                |                                            |
| [LINK]                               | Communication cycle of the target station  |
| [VAR] With a network label specified |                                            |
| [AXIS]                               |                                            |
| [AXIS]                               | Control operation cycle of the target axis |

- MC\_TouchProbe (Touch Probe Enabled) is executed even if the target axis is unconnected or an error occurs.
- The time for each TRUE and FALSE of the trigger input signal must be longer than the following. If the time is short, the signal cannot be detected correctly.

| External signal high-accuracy input | The time for each TRUE and FALSE of the trigger input signal                                                                                         |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use                                 | <ul style="list-style-type: none"> <li>Device station: Device station filter time</li> <li>Input module: Input module input response time</li> </ul> |
| Not use                             | Trigger input signal detection cycle                                                                                                                 |

- The interval for trigger input signals must be at least twice as long as the longer of either the trigger input signal detection cycle or latch cycle. If the interval is shorter than that, the signal cannot be detected correctly. If multiple trigger input signals are input before latching, the first input signal is used.

**Ex.**

If the detection cycle of the trigger input signal is the first operation cycle and the latch cycle is the second operation cycle

## Program example

The following is a program example. The touch probe start (bTouchProbe) is set to TRUE, and the actual position of Axis 1 (Axis0001) is estimated and calculated on each rising edge of the touch probe signal (G\_bTouchProbeSignal) in the motion system. After the actual position is stored in Latch position (leRecordedPosition), the Touch Probe Disabled start (bAbortTrigger) is set to TRUE and the latch operation is stopped.

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■I/O data

| Data name      | Data category  | Data type      | Source category | Source              | Signal detection method                              |
|----------------|----------------|----------------|-----------------|---------------------|------------------------------------------------------|
| SignalData0001 | Trigger signal | MC_TRIGGER_REF | Global label    | G_bTouchProbeSignal | Detection at FALSE → TRUE (rising edge) (RisingEdge) |

### ■Global labels used

| Label name          | Data type | Comment            |
|---------------------|-----------|--------------------|
| G_bTouchProbeSignal | Bit       | Touch probe signal |

### ■Labels used

|-----------------|----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion | BOOL       | FALSE         | This variable becomes TRUE when the control is completed.                                                                                                   |
| Busy            | Executing            | BOOL       | FALSE         | This variable becomes TRUE when MC_AbortTrigger (Touch Probe Disabled) is executed.                                                                         |
| Error           | Error                | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code           | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- This FB disables the MC\_TouchProbe (Touch Probe Enabled) set in Touch probe ID (TouchProbeID).
- When MC\_AbortTrigger (Touch Probe Disabled) is executed, if the MC\_TouchProbe (Touch Probe Enabled) set in Touch probe ID (TouchProbeID) is not in operation, Execution completion (Done) immediately becomes TRUE.
- Axis information (Axis) and Trigger input signal (TriggerInput) can be omitted, because they are ignored.

### ■ Timing chart

- When the processing is completed successfully

When Latch mode (RecordMode) is "2: Ring buffer mode (RingBuffer)"

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Trigger input signal (TriggerInput)

Trigger input signal is set in the MC\_TRIGGER\_REF structure. For the MC\_TARGET\_REF structure, refer to the following.

📖 Page 1487 MC\_TRIGGER\_REF

The setting range for Trigger input signal (Signal) of the MC\_TRIGGER\_REF structure set in Trigger input signal (TriggerInput) is shown below.

The type for Trigger signal (Signal) is SIGNAL\_SELECT structure. For the SIGNAL\_SELECT structure, refer to the following.

📖 Page 1492 SIGNAL\_SELECT (Signal select)

## Program example

The following is a program example. The touch probe start (bTouchProbe) is set to TRUE, and the actual position of Axis 1 (Axis0001) is estimated and calculated on each rising edge of the touch probe signal (G\_bTouchProbeSignal) in the motion system. After the actual position is stored in Latch position (leRecordedPosition), the Touch Probe Disabled start (bAbortTrigger) is set to TRUE and the latch operation is stopped.

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■I/O data

| Data name      | Data category  | Data type      | Source category | Source              | Signal detection method                              |
|----------------|----------------|----------------|-----------------|---------------------|------------------------------------------------------|
| SignalData0001 | Trigger signal | MC_TRIGGER_REF | Global label    | G_bTouchProbeSignal | Detection at FALSE → TRUE (rising edge) (RisingEdge) |

### ■Global labels used

| Label name          | Data type | Comment            |
|---------------------|-----------|--------------------|
| G_bTouchProbeSignal | Bit       | Touch probe signal |

### ■Labels used

| ExecutionMode  | Execution mode                  | INT (MC_EXECUTION_MODE) | At start | 0, 1, 3       | 0             | The execution timing of MC_CamTableSelect (Cam Table Selection) is set.<br><ul style="list-style-type: none"> <li>0: Execute immediately (mcImmediately)</li> <li>1: Execute at completion (mcQueued)</li> <li>3: Execute speculatively (mcSpeculatively)</li> </ul> For details, refer to the following.<br> Page 1608 Execution mode (ExecutionMode) |

## Output variables

| Output variable | Name         | Data type  | Default value | Description                                                                                                                                                                                                                                                                                                                                  |
|-----------------|--------------|------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Completion   | BOOL       | FALSE         | This variable becomes TRUE when the control is completed.<br>The value differs depending on the status of Start (Execute) at operation completion.<br>■When Start (Execute) is TRUE<br>This variable remains TRUE until Start (Execute) is set to FALSE.<br>■When Start (Execute) is FALSE<br>This variable becomes TRUE only for one cycle. |
| Busy            | Executing    | BOOL       | FALSE         | This variable becomes TRUE when MC_CamTableSelect (Cam Table Selection) is executed.                                                                                                                                                                                                                                                         |
| Error           | Error        | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                                                                                                             |
| ErrorID         | Error code   | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used                                                                                              |
| CamTableID      | Cam table ID | MC_CAM_ID  | 0             | The profile ID is output.                                                                                                                                                                                                                                                                                                                    |

## Processing details

- This FB opens the operation profile data (cam data) file set in Operation profile data storage location (Location) of the PROFILE\_DATA structure to the open area by using MC\_CamTableSelect (Cam Table Selection).
- Data opened in the open area is assigned the Profile ID (Number) of the PROFILE\_ID structure.

### Point

- For details on creating operation profile data (cam data), refer to the following.  
 User's manual for the controller used
- MC\_CamTableSelect (Cam Table Selection) is performed with Motion service processing. It may take time to open depending on the processing details and the operation profile data.
- When Profile\_ID (ID) of the PROFILE\_DATA structure, Periodic (Periodic), Master axis absolute coordinate (MasterAbsolute), and Slave axis absolute coordinate (SlaveAbsolute) are present as input variables for MC\_CamTableSelect (Cam Table Selection), the file setting values are ignored and the open is performed while referencing the input variable settings. (The setting values of the file will not be overwritten.)

## ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Cam table (CamTable)

Sets the operation profile data with the MC\_CAM\_REF type PROFILE\_DATA structure. For the PROFILE\_DATA structure, refer to the following.

📖 Page 1492 PROFILE\_DATA

References operation profile data storage location (Location) of the PROFILE\_DATA structure and performs open for the operation profile data that File name (FileName) and Folder specification (Path) indicate.

Profile ID No. (Number) of the PROFILE\_ID structure indicated by Profile ID (ID) of the PROFILE\_DATA structure is assigned in the open area.

The operation changes depending on the value set in Profile ID No. (Number).

| Profile ID No. (Number)  | Operation                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When set to "0"          | An available ID is automatically assigned and stored in Profile ID No. (Number).<br>If an MC_CamTableSelect (Cam Table Selection) with Profile ID No. (Number) set to "0" is executed multiple times to the same operation profile data, the data will be opened in multiple different open areas.<br>When no ID is available, Insufficient Operation Profile Data ID (error code: 1BA0H) will occur and open processing will not be performed. |
| When set to "1 to 60000" | The set ID is opened without changing the ID.<br>If specifying an ID that has already been opened, the open data will be overwritten.                                                                                                                                                                                                                                                                                                           |

The relationship between the value of Profile ID No. (Number) at open and the open location area is shown below.

| Profile ID No. (Number) value                            |                                                         | Open location area                                                                                           |
|----------------------------------------------------------|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Before executing MC_CamTableSelect (Cam Table Selection) | After executing MC_CamTableSelect (Cam Table Selection) |                                                                                                              |
| 0                                                        | Stores 1 to 60000                                       | New area                                                                                                     |
| 1 to 60000                                               |                                                         | Open data is overwritten if already existing.<br>When open data does not exist, a new open area is assigned. |

- For the function specific type, the same value as PROFILE\_DATA.ID (such as MC\_CAM\_REF.ProfileData.ID) is stored in the function specific type profile ID (such as MC\_CAM\_ID.ProfileID). For input variables of operation profile data control FBs (such as MC\_CamIn), set a function specific type profile ID.

For details on the profile ID type, refer to the following.

📖 User's manual for the controller used

- When executing an open FB, MC\_CAM\_REF.CamID.ProfileID does not need to be set. The set value for MC\_CAM\_REF.ProfileData.ID is referred to.

For the open FB list, refer to the following.

📖 User's manual for the controller used

- If the operation profile data set in Operation profile data storage location (Location) does not exist, No Operation Profile Data (error code: 1B8EH) occurs and the open processing is not performed.
- If the operation profile data set in Operation profile data storage location (Location) is broken or there is a problem in the format, Operation Profile Data Error (error code: 1B91H) occurs and the open processing is not performed.
- If the operation profile setting value specified in Operation profile data storage location (Location) is outside the range, Operation Profile Data Incorrect (error code: 1B8FH) occurs and the open processing is not performed.

### Ex.

If the resolution (4th row, 1st column) is outside the range, the row number in the file is stored as the data number, and the column number in the file is stored as the item number.

Detailed information 1 (Program error information)

Instance name: (FB instance name)

Detailed information 2 (Data error information)

Detail code: 1004H The operation profile data setting value is outside the range.

Data No.: 4

Item No.: 1

Data name: calc\_profile/PD00/ProfileData0001.CSV

■Periodic (Periodic)

Sets the operation performed by Periodic (Periodic) at operation profile data control execution.

| Setting value        | Description                                                                          |
|----------------------|--------------------------------------------------------------------------------------|
| FALSE (Non periodic) | The control ends when it executes until the end point of the operation profile data. |
| TRUE (Periodic)      | Continuously repeats operation profile data execution.                               |

■Master axis absolute coordinate (MasterAbsolute)

Sets the operation performed by Master axis absolute coordinate (MasterAbsolute) at operation profile data control execution.  
(When the input unit is time specification, it is ignored.)

| Setting value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE (Relative coordinate) | <p>The current Master axis (Master) value becomes the start point of the operation profile data. When In synchronization (InSync) becomes TRUE, Slave axis (Slave) is operated according to the relative movement amount of Master axis (Master).</p>  <p>The diagram consists of three vertically stacked graphs sharing a common horizontal time axis. The top graph shows the Master axis position over time, represented by a wavy line labeled '(Example) Profile data'. The middle graph shows the InSync status as a step function that transitions from FALSE to TRUE at a specific time point. The bottom graph shows the Slave axis position over time. When InSync becomes TRUE, the Slave axis starts moving according to the Master axis profile data, with its position relative to the Master axis starting at zero.</p> |
| TRUE                        | <p>Cannot be set to TRUE.</p> <p>If set to TRUE, Out of MasterAbsolute Range (error code: 1B94H) occurs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

# ■Slave axis absolute coordinate (SlaveAbsolute)

Sets the operation performed by Slave axis absolute coordinate (SlaveAbsolute) at operation profile data control execution.

| Setting value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE (Relative coordinate) | <p>When In synchronization (InSync) becomes TRUE, Slave axis (Slave) is operated based on the current value.</p> <p>Start point for operation profile data</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TRUE (Absolute coordinate)  | <p>Operates so that Slave axis (Slave) at the time that In synchronization (InSync) becomes TRUE is always the start point at the start of each cycle of the operation profile data.</p> <p>When there is a limit on the value of Master axis (Master) of the operation profile data, such as the cam data length per cycle, and the start point and end point of the operation profile data are different when Periodic (Periodic) is "TRUE: Periodic", the command is output in one operation cycle to return to the first Slave axis (Slave) at the start of the next cycle.</p> <p>Start point for operation profile data</p> |

## ■Execution mode (ExecutionMode)

This variable sets the timing for executing MC\_CamTableSelect (Cam Table Selection).

| Setting value                                 | Description                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Execute immediately<br>(mcImmediately)     | The contents of the open area are immediately written.<br>The writing may affect the control in execution.<br>Note that if the operation profile data format and resolution do not match when performing open during FB execution, Operation Profile Data Being Operated (error code: 1B90H) occurs. |
| 1: Execute at completion (mcQueued)           | Opens after waiting for the FB being executed to complete.<br>When multiple FBs are waiting, the FBs will be executed in order of task priority.<br>FBs of the same priority are executed according to the start order.                                                                              |
| 3: Execute speculatively<br>(mcSpeculatively) | Operation Profile Data Being Operated (error code: 1B90H) occurs and the open area is not changed.                                                                                                                                                                                                   |

### Point

When no FB is in execution, the FB is executed immediately regardless of the setting of Execution mode (ExecutionMode).

When FBs in execution are accessing the open area, Executing (Busy) of each FB accessing the open area becomes TRUE. Use Execution mode (ExecutionMode) for the interlock as needed.

## Precautions

When rewriting the open area during control, some waveform patterns may cause the stroke value may change rapidly and apply shock to the machine. Create operation profile data so that the waveform does not become discontinuous before or after the stroke value changes.

## Program example

The following is a program example. The cam table select command (bCamTableSelect) is set to TRUE, and the operation profile data (Cam data 1) is opened to the open area and a profile ID is assigned.

### Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### Operation profile data

| Profile ID | Label name      | Data type  | Comment    |
|------------|-----------------|------------|------------|
| 1          | ProfileData0001 | MC_CAM_REF | Cam data 1 |

### Labels used

| Label name          | Data type                           | Comment                  |
|---------------------|-------------------------------------|--------------------------|
| MC_CamTableSelect_1 | MC_CamTableSelect                   | Cam Table Selection FB   |
| CamTable            | MC_CAM_REF                          | Cam table                |
| bCamTableSelect     | Bit                                 | Cam table select command |
| bDone               | Bit                                 | Execution completion     |
| bBusy               | Bit                                 | Executing                |
| bError              | Bit                                 | Error                    |
| uwErrorID           | Word [unsigned]/bit string [16-bit] | Error code               |
| CamTableID          | MC_CAM_ID                           | Cam table ID             |

### FBD/LD program

- Operation profile data (cam data) settings

- Cam Table Selection

## ■ST program

//-----Operation profile data (cam data) settings-----

CamTable.ProfileData:= ProfileData0001.ProfileData;

//-----Cam Table Selection-----

```
MC_CamTableSelect_1(  
  CamTable:= CamTable ,  
  Execute:= bCamTableSelect ,  
  Periodic:= TRUE ,  
  MasterAbsolute:= FALSE ,  
  SlaveAbsolute:= FALSE ,  
  ExecutionMode:= MC_EXECUTION_MODE__mclImmediately ,  
  Done=> bDone ,  
  Busy=> bBusy ,  
  Error=> bError ,  
  ErrorID=> uwErrorID ,  
  CamTableID=> CamTableID  
);
```

# 45.14 Current Value Change per Cycle

45

## MCv\_ChangeCycle

This FB changes the current value per cycle of the specified operation profile data control FB.

| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used                                                                                                |
| CancelAccepted  | Cancel acceptance     | BOOL       | FALSE         | This variable becomes TRUE when MCv_ChangeCycle (Current Value Change per Cycle) accepts the cancel.                                                                                                                                                                                                                                         |

## Processing details

- This FB changes the current value per cycle of the operation profile data control FB to the value set at execution of control.
- Sets Instance ID (InstanceID) of the public variable of an operation profile data control FB (such as MC\_CamIn) in InstanceID (InstanceID).
- Upon performing the current value per cycle change, the public variable of the operation profile data control FB (such as MC\_CamIn) changes as shown below.

| Public variable                         | Updated value                                              | Remark                                                                |
|-----------------------------------------|------------------------------------------------------------|-----------------------------------------------------------------------|
| Current value per cycle (InputPerCycle) | Value set in Current value per cycle (Cycle)               | —                                                                     |
| Reference value (Reference)             | Stroke value equivalent to Current value per cycle (Cycle) | Updates Reference value (Reference) to fix Output value (OutputData). |
| Output value (OutputData)               | No value updated                                           | —                                                                     |

### Point

Reference value (Reference) is updated to fix Output value (OutputData) when performing current value per cycle change. This occurs even when Slave axis absolute coordinate (SlaveAbsolute) of MC\_CamTableSelect (Cam Table Selection) is set to TRUE (Absolute coordinate).

- The method for current value per cycle change is as follows.

| Method                                           | Description                                            |
|--------------------------------------------------|--------------------------------------------------------|
| MCv_ChangeCycle (Current Value Change per Cycle) | Change it to the specified value at control execution. |

- For specification of the current value per cycle to be changed, "absolute specification" or "relative specification" can be selected by Relative position selection (Relative).
- If Current value change per cycle is performed for an operation profile data control FB other than MC\_CamIn (Cam Operation Start), Current value per cycle change unsupported (error code: 1BAFH) occurs.

## ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

☞ Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Current value per cycle (Cycle)

Sets the current value per cycle to be changed.

Values settable for Current value per cycle (Cycle) differ depending on the setting of Relative selection (Relative). Set the variable within the setting range shown below. If a value outside the range is set, MCv\_ChangeCycle Instruction Error (error code: 1BB9H) (detail code: 0001H) occurs.

| Current value per cycle (Cycle) | Setting value of Relative selection (Relative) | Setting range of Current value per cycle (Cycle)                                      |
|---------------------------------|------------------------------------------------|---------------------------------------------------------------------------------------|
| Cycle[0]                        | FALSE (Absolute position)                      | $0.0 \leq \text{Setting value} < \text{Current value per cycle}$                      |
|                                 | TRUE (Relative distance)                       | $-(\text{Cycle length}) / 2 \leq \text{Setting value} \leq (\text{Cycle length}) / 2$ |
| Cycle[1], Cycle[2]              | FALSE (Absolute position)                      | 0.0                                                                                   |
|                                 | TRUE (Relative distance)                       |                                                                                       |

## ■Relative Selection (Relative)

The value of Current value per cycle (Cycle) is changed as shown below based on the setting of Relative selection (Relative).

| Setting value of Relative selection (Relative) | Description                                                                                                                                                                                          |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE (Absolute position)                      | Changes Current value per cycle (InputPerCycle) <sup>*1</sup> to a value equal to Current value per cycle (Cycle) added to the presently set Current value per cycle (InputPerCycle) <sup>*1</sup> . |
| TRUE (Relative distance)                       | Current value per cycle (InputPerCycle) <sup>*1</sup> is changed to the value of Current value per cycle (Cycle).                                                                                    |

<sup>\*1</sup> Public variable of operation profile data control FBs (such as MC\_CamIn)

### Ex.

When public variable Current value per cycle (InputPerCycle) is "180.0" at stop, and a current value per cycle change of "90.0" is set in Current value per cycle (Cycle)

• When Relative selection (Relative) is FALSE (Absolute position)

• When Relative selection (Relative) is TRUE (Relative distance)

The following table shows whether or not exceeding the current value per cycle is possible when the current value per cycle is changed.

○: Exceeding possible, ×: Exceeding not possible

| Setting value of Relative selection (Relative) | Relationship between 1 cycle and amount moved by the current value per cycle | Exceeding Possible |
|------------------------------------------------|------------------------------------------------------------------------------|--------------------|
| FALSE (Absolute position)                      | 1 cycle > movement amount of the current value per cycle                     | ×                  |
| TRUE (Relative distance)                       | 1 cycle > movement amount of the current value per cycle                     | ○                  |
|                                                | 1 cycle ≤ movement amount of the current value per cycle                     | ○ <sup>*1</sup>    |

<sup>\*1</sup> The operation when exceeding occurs will differ based on the set values for Periodic (Periodic) set under MC\_CamTableSelect (Cam Table Selection)

| Setting value of Periodic (Periodic) | Description                                                 |
|--------------------------------------|-------------------------------------------------------------|
| FALSE (Non periodic)                 | Movement amount exceeding 1 cycle is disposed.              |
| TRUE (Periodic)                      | Changes the current value per cycle when exceeding 1 cycle. |

### Ex.

When the Current Value per Cycle (Cycle) changes from "320.0" to "30.0"

• When Periodic (Periodic) is FALSE (Non periodic).

• When Periodic (Periodic) is TRUE (Periodic).

## ■Execution mode (ExecutionMode)

When MCv\_ChangeCycle (Current Value Change per Cycle) is executed, the timing for the current value per cycle change differs depending on the setting of Execution mode (ExecutionMode). The timing for Execution mode (ExecutionMode) is shown below.

| Setting value                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Execute immediately (mclImmediately) | <p>Immediately executes using Start (Execute) rising edge detection regardless of whether Executing (Busy) of the operation profile data control FB (such as MC_CamIn) is TRUE.</p> <p>&lt;Example&gt;</p> <p>When current value per cycle change is executed while Executing (Busy) of MC_CamIn (Cam Operation Start) is TRUE and "100.0" is set in Current value per cycle (Cycle) (The current value for Master axis (Master) of MC_CamIn (Cam Operation Start) is considered as not being changed.)</p> <p>The diagram shows the timing of the MC_CamIn and MCv_ChangeCycle function blocks. The MC_CamIn block is shown with its inputs and outputs. The MCv_ChangeCycle block is shown with its inputs and outputs. The diagram illustrates the timing of the execution of these function blocks and the resulting changes in the current value per cycle.</p> <p>*1 Does not change because the master axis does not move.</p> <p>*2 At current value change per cycle completion, Completion (Done) becomes TRUE and Executing (Busy) becomes FALSE.</p> <p>*3 The instance ID of the FB that executes the current value change per cycle is set manually.</p> |

■Options (Options)

The function options for MCv\_ChangeCycle (Current Value Change per Cycle) are set in the specified bit position. The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name                           | Description                                                                                                                                                                                  |
|-----|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Cancel accepted after FB start | Sets whether or not to allow a cancel after MCv_ChangeCycle (Current Value Change per Cycle) is executed. <ul style="list-style-type: none"><li>• 0: Disabled</li><li>• 1: Enabled</li></ul> |

- A current value per cycle change that is in standby status can be cancelled after FB execution by setting Cancel accepted after FB start.
  - The cancel is started at falling edge detection of Start (Execute).
  - The cancel is accepted only when Executing (Busy) is TRUE.
  - When the FB accepts the cancel, Cancel acceptance (CancelAccepted) becomes TRUE.
  - When the cancel is completed, Abortion of execution (CommandAborted) becomes TRUE.
  - When the cancel was performed, Current value per cycle (InputPerCycle) is not changed.

## Program example

The following is a program example. The current value change per cycle command (bChangeCycle) is set to TRUE, and the current value per cycle of the Instance ID (InstanceID) set to "1" is changed to "90.0".

### Setting data

#### I/O variables

| I/O variable | Name             | Data type | Input    | Setting range | Default value     | Description                   |
|--------------|------------------|-----------|----------|---------------|-------------------|-------------------------------|
| Axis         | Axis information | AXIS_REF  | At start | —             | Omission possible | The setting value is ignored. |

#### Input variables

| Input variable | Name             | Data type | Input  | Setting range | Default value | Description                                                                                                                                                                                |
|----------------|------------------|-----------|--------|---------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable         | Enable           | BOOL      | Always | TRUE, FALSE   | FALSE         | When this variable is set to TRUE, control of the specified axis is enabled (operation possible status).<br>When this variable is set to FALSE, control of the specified axis is disabled. |
| ServoON        | Servo ON request | BOOL      | Always | TRUE, FALSE   | FALSE         | When this variable is set to TRUE, the servo ON is requested to the specified axis.                                                                                                        |

#### Output variables

| Output variable | Name       | Data type  | Default value | Description                                                                                                                                                 |
|-----------------|------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Busy            | Executing  | BOOL       | FALSE         | This variable becomes TRUE when MCv_AllPower (All Axes Operation Available) is executed.                                                                    |
| Error           | Error      | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- This FB initializes the information of all axes and switches the axis status to the operation available status.
- When the Enable (Enable) and Servo ON request (ServoON) inputs are set to TRUE, every axis is switched to the operation available status.
- Starting the processing causes Executing (Busy) to become TRUE.
- When an error occurs in MCv\_AllPower (All Axes Operation Available), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- Inputting Enable (Enable) and Servo ON request (ServoON) switches the servo ON/OFF status and the drive unit status of the all real axes as shown below.

| Input variables |                            | Servo ON/OFF status | Driver status<br>(AxisName.Md.Driver_State) |
|-----------------|----------------------------|---------------------|---------------------------------------------|
| Enable (Enable) | Servo ON request (ServoON) |                     |                                             |
| TRUE            | TRUE                       | Servo ON            | 6: Operation Enable (OperationEnable)       |
|                 | FALSE                      | Servo OFF           | 5: Switched On (SwitchedOn)                 |
| FALSE           | TRUE                       | Servo OFF           | 3: Switched On Disabled (SwitchOnDisabled)  |
|                 | FALSE                      | Servo OFF           | 3: Switched On Disabled (SwitchOnDisabled)  |

- If the real axis is rotated by external force during the servo OFF status, follow up processing is performed.
- The servo ON/OFF control can be operated regardless of the control mode. The control mode during servo OFF depends on the specifications of the drive unit.
- MCv\_AllPower (All Axes Operation Available) is sent to the drive unit while a drive unit error is occurring, so Enable (Enable) and Servo ON request (ServoON) do not need to be turned from FALSE to TRUE again.

### Point

Use MCv\_AllPower (All Axes Operation Available) and MC\_Power (Operation Available) together if executing servo OFF individually.

When MCv\_AllPower (All Axes Operation Available) and MC\_Power (Operation Available) are used together, the MC\_Power (Operation Available) command is given priority.

## Timing chart

**Ex.**

When Axis 2 (Axis0002) and Axis 3 (Axis0003) are set as real drive axes

## Precautions

- For axes setting MC\_Power (Operation Available), the MC\_Power (Operation Available) command is given priority for switching to operable status.
- The servo ON/OFF status when stopping the program is maintained while Built-in motion ready (X420) is off.

## Program example

The following is a program example. All the axes servo ON/OFF (bAllServoON) is set to TRUE, and all axes are switched to operation possible status.

### Labels used

| Label name     | Data type                           | Comment               |
|----------------|-------------------------------------|-----------------------|
| MCv_AllPower_1 | MCv_AllPower                        | All axes servo ON FB  |
| bAllServoON    | Bit                                 | All axes servo ON/OFF |
| bBusy          | Bit                                 | Executing             |
| bError         | Bit                                 | Error                 |
| uwErrorID      | Word [unsigned]/bit string [16-bit] | Error code            |

#### Input variable

| Input variable | Name                         | Data type | Input  | Setting range       | Default value | Description                                                                                                                                                                                                                          |
|----------------|------------------------------|-----------|--------|---------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable         | Enable                       | BOOL      | Always | TRUE, FALSE         | FALSE         | When this variable is set to TRUE, MC_GroupSetOverride (Axes Group Override Value Setting) is executed.                                                                                                                              |
| VelFactor      | Velocity override factor     | LREAL     | Always | 0.00 to 10.00       | 0.00          | The velocity override factor is set.<br>When Enable (Enable) is TRUE, the value is always imported.                                                                                                                                  |
| AccFactor      | Acceleration override factor | LREAL     | Always | 0.00, 0.01 to 10.00 | 0.00          | The acceleration override factor is set.<br>When Enable (Enable) is TRUE, the value is always imported.<br>When "0.00" is set, the acceleration override factor is not changed and the control is performed with the previous value. |
| JerkFactor     | Jerk override factor         | LREAL     | Always | 0.0                 | 0.0           | "0.0" must be set.<br>* If a value other than "0.0" is set, Out of Jerk Override Coefficient (JerkFactor) Range (error code: 1BBEH) occurs.                                                                                          |

#### Output variables

| Output variable | Name       | Data type  | Default value | Description                                                                                                                                                 |
|-----------------|------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enabled         | Enabled    | BOOL       | FALSE         | This variable becomes TRUE when the override values are set correctly.                                                                                      |
| Busy            | Executing  | BOOL       | FALSE         | This variable becomes TRUE when MC_GroupSetOverride (Axes Group Override Value Setting) is executed.                                                        |
| Error           | Error      | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- This FB changes the target velocity, the target acceleration, and the target deceleration of the specified axes group.
- The current operating target velocity, target acceleration, and target deceleration values are changed by multiplying each value by the override factor.
- MC\_GroupSetOverride (Axes Group Override Value Setting) is executed when Enable (Enable) becomes TRUE. Enabled (Enabled) becomes TRUE while the override factor is valid.
- If the override factor value is changed while Enable (Enable) is TRUE, the new override factor is reflected.
- When an error occurs in MC\_GroupSetOverride (Axes Group Override Value Setting), Error (Error) becomes TRUE and the error code is stored in Error code (ErrorID). For details on error codes, refer to the following.

 User's manual for the controller used

- When the value for Velocity override factor (VelFactor) is set to "0.00", the axis stops without Axis status (AxisName.Md.AxisStatus) changing to "4: Standby (Standstill)".
- When the value for Acceleration override factor (AccFactor) is set to "0.00", the acceleration override factor is not changed and the previous acceleration override factor is maintained.

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1435 Basic operation of Enable (Enable) type motion control FBs

## ■ Operation overview

- In MC\_GroupSetOverride (Axes Group Override Value Setting), Velocity override factor (AxesGroupName.Cd.VelocityOverride) and Acceleration override factor (AxesGroupName.Cd.AccelerationOverride) are changed.

- If the override factor is set to a value outside the range, an error will occur in MC\_GroupSetOverride (Axes Group Override Value Setting) and subsequent values will not be imported. To import values again, restart Enable (Enable).

## Precautions

- Do not assign two or more MC\_GroupSetOverride (Axes Group Override Value Setting) FBs in the same axes group. The operation is not guaranteed if two or more of this FB are set.
- For axes group control, only the override factor set with the axes group control data has an effect.
- While executing MC\_GroupSetOverride (Axes Group Override Value Setting), do not perform direct operation of Velocity override factor (AxesGroupName.Cd.VelocityOverride) and Acceleration override factor (AxesGroupName.Cd.AccelerationOverride).
- When the speed after Speed override is out of range, refer to "Velocity Range" in the following.

📖 User's manual for the controller used

- When the acceleration, deceleration, acceleration time, and deceleration time after acceleration override is out of range, refer to "Acceleration/deceleration processing function" in the following.

📖 User's manual for the controller used

## Program example

The following is a program example. The axes group override value change command (bGroupSetOverride) is set to TRUE, and the target velocity, target acceleration, and target deceleration of Axes group 1 (AxesGroup001) are changed to values multiplied by a velocity override factor of "1.0" and an acceleration override factor of "2.0".

| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when MCv_MotionErrorReset (Motion Error Reset) has been aborted because of timeout. The variable becomes FALSE when Execution command (Execute) becomes FALSE. |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                          |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code. For details on error codes, refer to the following.<br>User's manual for the controller used                                  |

## Processing details

- MCv\_MotionErrorReset (Motion Error Reset) is executed when Execution command (Execute) is set to TRUE. When the processing starts, Executing (Busy) becomes TRUE and System error reset (MotionSystem.Cd.ErrorReset) also becomes TRUE.
- Once errors and warnings have been cleared for the Motion system, Executing (Busy) becomes FALSE and Execution completion (Done) becomes TRUE.
- Setting Execution command (Execute) to TRUE while the causes of the errors and warnings remain does not clear the errors and warnings. In addition, if the errors are not cleared within two seconds after this FB is executed, Abortion of execution (CommandAborted) becomes TRUE and changes System error reset (MotionSystem.Cd.ErrorReset) to FALSE. Turn Execution command (Execute) to FALSE temporarily and clear the error and warning causes, then set Execution command (Execute) to TRUE again.

### ■Timing chart

- When the processing is completed successfully

- At timeout

## Precautions

- For MCv\_MotionErrorReset (Motion Error Reset), the special relay (SM0) and the special register (SD0) are not cleared, and the ERROR LED of the module is not turned off. For the execution methods of the above operations, refer to the user's manual for the controller used.
- Do not directly operate System error reset (MotionSystem.Cd.ErrorReset) while MCv\_MotionErrorReset (Motion Error Reset) is being executed.

## Program example

The following is a program example. The error reset (bMotionErrorReset) is set to TRUE, and all errors and warnings of the motion system are reset.

# 45.18 Control Operation Cycle Synchronization

45

## MCv\_SyncOperationCycles

The control operation cycle of the axis is synchronized with the specified cycle.

Before using this FB, check the versions of the controller and engineering tool.

User's manual for the controller used

#### Output variable

| Output variable | Name       | Data type  | Default value | Description                                                                                                                                                 |
|-----------------|------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enabled         | Enabled    | BOOL       | FALSE         | This variable becomes TRUE when the control operation cycle synchronization is operating correctly.                                                         |
| Busy            | Executing  | BOOL       | FALSE         | This variable becomes TRUE when MCv_SyncOperationCycles (Control Operation Cycle Synchronization) is being executed.                                        |
| Error           | Error      | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- MCv\_SyncOperationCycles (Control Operation Cycle Synchronization) synchronizes with the cycle of the value to which the control operation cycle of the selected data (axis or data source) is set.
- This function block is used if the control operation cycles of the master axis and slave axis are not the same in the single axis synchronous control FB.
- When Enable (Enable) becomes TRUE, control operation cycle synchronization is enabled. While the control operation cycle synchronization is enabled, Enabled (Enabled) is TRUE.

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

## Precautions

- This FB synchronizes the selected data with the operation cycle during the specified control time but does not change the control operation cycle setting.
- When the control operation cycles are not the same between the input and the output (input: master axis, output: slave axis in synchronous control), start this FB before starting synchronous control. If synchronous control is started without synchronization, the operation cycle mismatch (error code: 1B29H) occurs.
- When this FB is executed, the operation time increases.
- The input argument refresh for a motion control FB is performed when the FB is read, but this FB is refreshed by the operation cycle, regardless of the FB call task (scan/fixed cycle/event).

## Program example

The following is a program example. Axes in different control cycles are synchronously controlled by using Control Operation Cycle Synchronization (MCv\_SyncOperationCycles).

This program example starts MC\_GearIn while handling Axis0001 to be controlled in the first operation cycle as the master axis and Axis0002 to be controlled in the second operation cycle as the slave axis.

The program that executes servo ON of the MR-J5-G is omitted.

### ■CC-Link IE TSN configuration

| Station No. | Type name | IP address  | Network synchronous communication setting | Communication period setting |
|-------------|-----------|-------------|-------------------------------------------|------------------------------|
| 1           | MR-J5-G   | 192.168.4.1 | Synchronize                               | Basic cycle                  |
| 2           | MR-J5-G   | 192.168.4.2 | Synchronize                               | Medium speed                 |

### ■Axes

| Axis No. | Label name | Station address setting | Axis type       | Control cycle setting                 |
|----------|------------|-------------------------|-----------------|---------------------------------------|
| 1        | Axis0001   | 192.168.4.1             | Real drive axis | Operate in the first operation cycle  |
| 2        | Axis0002   | 192.168.4.2             | Real drive axis | Operate in the second operation cycle |

# 45.19 Advanced Synchronous Control One Cycle Current Position Calculation

## MCv\_AdvPositionPerCycleCalc

This FB calculates the current position per cycle based on the specified cam data.

Before using, check the versions of the controller and engineering tool.

User's manual for the controller used

| Ladder diagram                                                                                                                                                                                                                                                                                                                                                                                                                         | FBD/LD                                                                                                                                                                                                                                                                                                                      | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Processing details

- The current position per cycle is calculated from cam data based on Cam position calculation cam reference position (ReferenceSetPosition) and Cam position calculation cam set position (SetPosition). The calculation result is output to Calculation result (CalculationResult).
- For details on the current position per cycle calculation, refer to the following.

 User's manual for the controller used

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## Precautions

- Before using the cam data, configure the open setting to automatically open the cam data to the open area, or open the data to the area using MC\_CamTableSelect (Cam Table Selection).
- Apply the calculation result of the current position per cycle calculation (MCv\_AdvPositionPerCycleCalc) only to MCv\_AdvancedSync (Advanced synchronous control). If the result is applied to a synchronous control FB (such as MC\_CamIn) other than MCv\_AdvancedSync (Advanced synchronous control), a mismatch occurs between the calculation result and the actual operation.
- For the current position per cycle calculation of coordinate data, the calculation result of the cam data last point may be as follows depending on the length per cycle. When coordinate data is used, matching the cam data last point with the length per cycle is recommended.

| Cam data last point               | Description                                                                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Greater than the length per cycle | The calculation result may differ from the synchronous control path because the entire range of the cam data is searched regardless of the length per cycle setting value. |
| Less than the length per cycle    | The current value per cycle may be greater than the length per cycle due to the relationship between the cam set position and the cam reference position.                  |

## Program example

For a program example of this FB, refer to the following.

 User's manual for the controller used

# 45.20 Cam Set Position Calculation in Advanced Synchronous Control

45

## MCv\_AdvCamSetPositionCalc

This FB calculates the cam set position based on the specified cam data.

Before using, check the versions of the controller and engineering tool.

User's manual for the controller used

## Setting data

### I/O variables

| I/O variable | Name             | Data type | Input    | Setting range | Default value     | Description             |
|--------------|------------------|-----------|----------|---------------|-------------------|-------------------------|
| Axis         | Axis information | AXIS_REF  | At start | —             | Omission possible | The setting is ignored. |

### Input variables

| Input variable      | Name                                   | Data type | Input    | Setting range                 | Default value | Description                                                                                                                                                                                                                                                                          |
|---------------------|----------------------------------------|-----------|----------|-------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Execute             | Execution command                      | BOOL      | At start | TRUE, FALSE                   | FALSE         | This FB is executed when the value is TRUE.                                                                                                                                                                                                                                          |
| CamTableID          | Cam table ID                           | MC_CAM_ID | At start | 0 to 6000                     | 0             | The operation cam table ID of the calculation target is set. When "0" is set in Profile ID No. (Number) of the PROFILE_ID structure, the target is calculated as a linear cam.                                                                                                       |
| RingCountUpperValue | Ring counter upper limit               | LREAL     | At start | 0.0, 2.0 to 2147483647.0      | 0.0           | The ring counter upper limit value for the calculation target output axis is set when the ring counter upper limit is to be considered in cam position calculations. When "0.0" is set, the calculation is performed with the ring counter set as "-10000000000.0 to 10000000000.0". |
| LengthPerCycle      | Cam position one cycle length          | LREAL     | At start | 1.0 to 2147483647.0           | 1.0           | The length per cycle required for the cam calculation is set.                                                                                                                                                                                                                        |
| StrokeAmount        | Cam position calculation stroke amount | LREAL     | At start | -2147483648.0 to 2147483647.0 | 0.0           | The cam stroke amount required for the cam calculation is set.                                                                                                                                                                                                                       |

| Input variable       | Name                                                   | Data type  | Input    | Setting range                      | Default value | Description                                                                                                                                                                                     |
|----------------------|--------------------------------------------------------|------------|----------|------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ReferenceSetPosition | Cam position calculation<br>cam reference position     | LREAL      | At start | -10000000000.0 to<br>10000000000.0 | 0.0           | The cam reference position required for the cam calculation is set.                                                                                                                             |
| PositionPerCycle     | Cam position calculation<br>current position per cycle | LREAL      | At start | 0.0 to 2147483647.0                | 0.0           | The current position per cycle required for the cam calculation is set. Set the value within the following range.<br>0.0 to the setting value of Cam position one cycle length (LengthPerCycle) |
| StartingPoint        | Cam position calculation<br>cam start point            | DWORD      | At start | 0 to 65535                         | 0             | This variable is set when the cam start point is to be considered in the cam calculation.                                                                                                       |
| Options              | Options                                                | DWORD(HEX) | At start | Fixed to 0                         | 0             | This variable cannot be set for this FB. Set 0. If a value other than 0 is set, Out of options range (error code: 1ABBH) occurs.                                                                |

## ■Output variables

| Output variable   | Name                 | Data type  | Default value | Description                                                                                                                                                                                                                                    |
|-------------------|----------------------|------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalculationResult | Operation result     | LREAL      | 0.0           | The calculation result of the cam set position is stored.                                                                                                                                                                                      |
| Done              | Execution completion | BOOL       | FALSE         | This variable becomes TRUE when the calculation is completed.                                                                                                                                                                                  |
| Busy              | Executing            | BOOL       | FALSE         | This variable becomes TRUE when this FB is executed.                                                                                                                                                                                           |
| Error             | Error                | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                               |
| ErrorID           | Error code           | WORD(UINT) | 0             | When an error occurs, this variable returns the error code. For details on error codes, refer to the following.<br> User's manual for the controller used |

## ■Public variables

| Public variable | Name        | Data type   | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| InstanceID      | Instance ID | INSTANCE_ID | 0             | The instance ID is stored.<br>This variable is automatically set by the system when an instance is created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Processing details

- The cam set position is calculated based on Cam position calculation current position per cycle (PositionPerCycle) and Cam position calculation cam reference position (ReferenceSetPosition). The calculation result is output to Calculation result (CalculationResult).
- For details on the cam set position calculation, refer to the following.

📖 User's manual for the controller used

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## Precautions

- Before using the cam data, configure the open setting to automatically open the cam data to the open area, or open the data to the area using MC\_CamTableSelect (Cam Table Selection).
- Apply the calculation result of the cam set position calculation (MCv\_AdvCamSetPositionCalc) only to MCv\_AdvancedSync (Advanced synchronous control). If the result is applied to a synchronous control FB (such as MC\_CamIn) other than MCv\_AdvancedSync (Advanced synchronous control), a mismatch occurs between the calculation result and the actual operation.

## Program example

For a program example of this FB, refer to the following.

📖 User's manual for the controller used

# 45.21 Digital Cam Switch Output

## MC\_DigitalCamSwitch

This FB outputs the on/off signals according to a given data value.

Before using, check the versions of the controller and engineering tool.

User's manual for the controller used

| Options        | Options   | DWORD(HEX) | At start | —             | 00000000H     | The function options are set.<br>For details, refer to the following.<br> Page 1645 Options (Options)                                         |

## ■Output variables

| Output variable | Name         | Data type  | Default value | Description                                                                                                                                                                                                                                     |
|-----------------|--------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| InOperation     | In operation | BOOL       | FALSE         | This variable becomes TRUE when the output signal is valid.                                                                                                                                                                                     |
| Busy            | Executing    | BOOL       | FALSE         | This variable becomes TRUE when this FB is being executed.                                                                                                                                                                                      |
| Error           | Error        | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                |
| ErrorID         | Error code   | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## ■Public variables

| Public variable  | Name                       | Data type   | Default value | Description                                                                                                 |
|------------------|----------------------------|-------------|---------------|-------------------------------------------------------------------------------------------------------------|
| InputsPerCycle   | Current position per cycle | LREAL       | 0             | The data source value is stored.                                                                            |
| OutputData       | Output value               | BOOL        | 0             | The output value to the output signal is stored.                                                            |
| SwitchNo         | Switch number              | WORD (UINT) | 0             | The switch number of the switch that is on is stored.                                                       |
| CurrentProfileNo | Executing profile number   | WORD (UINT) | 0             | The profile ID of the profile currently being executed is stored.                                           |
| InstanceID       | Instance ID                | INSTANCE_ID | 0             | The instance ID is stored.<br>This variable is automatically set by the system when an instance is created. |

## Processing details

This FB judges whether a data source set for Data source selection (ValueSource) satisfies the switch setting condition and outputs the output signal. For details on the digital cam switch function, refer to the following.

 User's manual for the controller used

### ■Timing chart

For the timing chart of this FB, refer to the following.

 Page 1435 Basic operation of Enable (Enable) type motion control FBs

### ■Switches (Switches)

The operation profile ID is specified with an MC\_CAMSWITCH\_DATA\_REF structure.

For the setting method, refer to the following.

 User's manual for the controller used

If Switches (Switches) is changed to outside the range during execution or an open area does not exist, a program warning (event code: 00F19H) occurs, and the operation continues with the value before the change.

### ■Output signal (Outputs)

Output signals are set with an MC\_OUTPUT\_REF structure. For details on the MC\_OUTPUT\_REF structure, refer to the following.

 Page 1487 MC\_OUTPUT\_REF

The setting range for Output signal (Outputs) of the MC\_OUTPUT\_REF structure set in Output signal (Outputs) is shown below.

The type for Output signal (Outputs) is the SIGNAL\_SELECT structure. For the SIGNAL\_SELECT structure, refer to the following.

 Page 1492 SIGNAL\_SELECT (Signal select)

| Structures                    | Variable name                                         | Type                                                                                                                                         | Setting range                                                 |
|-------------------------------|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| SIGNAL_SELECT (Signal select) | Source (Signal)                                       | TARGET_REF<br> Page 1489<br>TARGET_REF (Input signal)     | ■Type<br>• BOOL<br>■Data category<br>• [LINK] <sup>*1</sup>   |
|                               | Detection (Signal detection method)                   | INT<br>(MC_SIGNAL_LOGIC)<br> Page 1524<br>MC_SIGNAL_LOGIC | The signal logic of the bit output signal cannot be selected. |
|                               | CompensationTime<br>(Compensation time) <sup>*2</sup> | LREAL                                                                                                                                        | -5.0 to 5.0 [s]                                               |
|                               | FilterTime (Filter time)                              | LREAL                                                                                                                                        | 0.0 [s] <sup>*3</sup>                                         |

\*1 When [LINK] is specified, writing to the corresponding network labels is ignored. The setting is only possible when the external signal high-accuracy output is used. For more details, check the user's manual for the controller used.

\*2 Set this variable when compensating for delays, such as those caused by the device response time. For details on time compensation, check the user's manual for the controller used.

\*3 If a value other than 0.0 is set, Out of filter time setting range of signal (error code: 1BC8H) occurs. To eliminate chattering, set Hysteresis (Switching disabled distance) of Track options (TrackOptions).

When an identical output signal is set for multiple FB instances, the logical sum of the output results is output.

The output signal is refreshed in the following timing, regardless of the program execution cycle used.

| Data category | Refresh timing                            |
|---------------|-------------------------------------------|
| [LINK]        | Communication cycle of the target station |

## ■Track options (TrackOptions)

Track options are set with an MC\_TRACK\_REF structure. For the MC\_TRACK\_REF structure, refer to the following.

📖 Page 1488 MC\_TRACK\_REF

The setting range for Track options (TrackOptions) of the MC\_TRACK\_REF structure to be set for Track options (TrackOptions) is shown below.

| Item                                     | Setting range        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hysteresis (Switching disabled distance) | 0.0 to 10000000000.0 | <p>Set the dead band to prevent chattering of the output signal when the speed of the data source is unstable.*1</p> <p>Use less than half of the data source ring counter range for the setting. If half or more of the data source ring counter range is used for the setting, an MC_DigitalCamSwitch instruction error (error code: 1BCAH) occurs.</p> <p>If the setting value is changed to a value outside the range during execution, a program warning (event code: 00F19H) occurs, and the operation continues with the value before the change.</p> <p>While the movement direction of the data source is within Hysteresis from the inverted position, changes in Hysteresis are not reflected to the control. The changes will be reflected to the control when out of Hysteresis.</p> |

\*1 For details, refer to the following.

(1) Hysteresis (Switching disabled distance)

- When Switch mode selection (CamSwitchMode) in the switch settings is set to "1: Position reference", the output signal is not switched between on and off within the range from the position where the data source change direction is reversed to Hysteresis (Switching disabled distance). When Direction selection (Direction) in the switch settings is set to "1: Positive Direction", the operation is as follows.

(1) Hysteresis (Switching disabled distance)

(2) The on/off switching of the output signal is not performed.

## ■Data source selection (ValueSource)

The following items are specified in the MC\_CAMSWITCH\_SOURCE\_REF structure.

- Data source
- Upper limit value and lower limit value of the data source

For details on the MC\_CAMSWITCH\_SOURCE\_REF structure, refer to the following.

📖 Page 1488 MC\_CAMSWITCH\_SOURCE\_REF

| Variable name                                                                      | Type                                                   | Setting range                                                                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

If the absolute value obtained by subtracting RingCount_LowerValue (Data source ring counter lower limit value) from RingCount_UpperValue (Data source ring counter upper limit value) is less than 2, an MC_DigitalCamSwitch instruction error (error code: 1BCAH) occurs.</p> <p>Ensure that the data source movement amount per refresh cycle is less than half of the data source ring counter range. If the movement amount of the data source per refresh cycle is equal to or more than half of the data source ring counter range, the direction cannot be determined properly and output signals cannot be output at the correct timing.</p> |
| RingCount_UpperValue<br>(Data source ring counter upper limit value) <sup>*2</sup> |                                                        |                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

\*1 ON section determination is performed as the LREAL type. When specifying data that is not the LREAL type, explicitly specify (LREAL) for the data type. When (LREAL) is not specified for the data type, External signal selection string incorrect (error code: 1B05H) occurs.

\*2 When [Axis] is specified for Source (Data source), the setting value is ignored because the axis data specified by the operand axis (Axis) is referred.

Multiple FB instances can be executed simultaneously on a single data source.

The output signal is refreshed in the following timing, regardless of the program execution cycle used.

| Data classification | Refresh timing                                                                                                  |
|---------------------|-----------------------------------------------------------------------------------------------------------------|
| [VAR]               | Network label: Communication cycle of the target station<br>Other than the network label: First operation cycle |
| [DEV]               | First operation cycle                                                                                           |
| [CONST]             |                                                                                                                 |
| [AXIS]              | Communication cycle of the target station                                                                       |

### ■ Forced off (ForcedOff)

The output signal is forcibly turned off during execution.

It is controlled with higher priority than Hysteresis (Switching disabled distance) of Track options (TrackOptions)

| Forced off (ForcedOff) status | Operation                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------|
| FALSE                         | The output signal is turned on/off based on the switch setting.<br>User's manual for the controller used |
| TRUE                          | The output signal is forcibly turned off.                                                                |

### ■ Forced on (ForcedOn)

The output signal is forcibly turned on during execution.

The output signal is forcibly turned on by setting Forced on (ForcedOn) to TRUE while Forced off (ForcedOff) is TRUE.

It is controlled with higher priority than Hysteresis (Switching disabled distance) of Track options (TrackOptions)

| Forced on (ForcedOn) status | Operation                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------|
| FALSE                       | The output signal is turned on/off based on the switch setting.<br>User's manual for the controller used |
| TRUE                        | The output signal is forcibly turned on.                                                                 |

### ■ Options (Options)

The function options for this FB are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, an MC\_DigitalCamSwitch instruction error (error code: 1BCAH) occurs and the function does not start.

| Bit | Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Output setting at FB stop | <p>When Enable (Enable) is changed from TRUE to FALSE, "PLC Ready (MotionSystem.Cd.SequenceReady)" is turned off, or an error occurs, set whether to hold or turn off the output signal when the FB stops.</p> <ul style="list-style-type: none"> <li>• 0: Hold</li> <li>• 1: Turn off</li> </ul> <p>The following figure shows the operation when "PLC Ready (MotionSystem.Cd.SequenceReady)" is switched during execution.</p> <p>■ Outputs: When [LINK] is specified<br/> For details on the output at controller STOP/error, refer to the following.<br/>  User's manual for the controller used<br/> Since the output to the link device RWw is held, the output hold/clear setting function of the remote I/O has priority. For details, refer to the following.<br/>  User's manual for the controller used</p> |

## Precautions

If the signal set for Output signal (Outputs) differs from Output value (OutputData), check whether the signal set for Output signal (Outputs) is manipulated by another function.

## 46.1 Homing

### MC\_Home

This FB executes homing for the specified axis.

| Ladder | FBD/LD | ST                                                                                                                                                                                                                                                                                          |

## ■ Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                   |
|-----------------|-----------------------|------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the homing is completed.                                                                                                                                                                                      |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MC_Home (OPR) is executed.                                                                                                                                                                                    |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MC_Home (OPR) is controlling the axis.                                                                                                                                                                       |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_Home (OPR) is aborted because of an error or multiple start.                                                                                                                                  |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                              |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

- In homing, a machine home position is established. The address information stored in the motion system and drive unit is not used during this process. The position mechanically established after the homing becomes the start point, or "home position", for positioning control.

- For the homing method, "Driver homing method" and "Data set homing method" are available.  
The homing method used at homing start is determined based on the following conditions.

| Homing method          | Condition for homing method                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Driver homing method   | Driver homing method is used when all of the following conditions are satisfied. <ul style="list-style-type: none"> <li>The axis type is real drive axis.</li> <li>The drive unit supports Homing mode.</li> <li>"Home offset (607CH)" is set for object data.</li> </ul> |
| Data set homing method | Data set homing method is used when the conditions listed above are not satisfied.                                                                                                                                                                                        |

## ■Driver homing method

The control mode of the drive unit is switched to the Homing mode, and the homing is executed based on the positioning pattern set on the drive unit side.

Change the homing data of the drive unit with MC\_WriteParameter (Parameter Write) to change the homing method or the parameters. Homing operation and settable parameters depend on the specifications of the drive unit. For details on the drive unit, refer to the manual for the drive unit.

- Timing chart

- Normal operation

The value also becomes "1H" when the home position has already been established.

\*1 When Follow-up enabled/disabled selection (Options (Options): Bit 16) is set to "0: Follow-up disabled", it will not update during homing. When set to "1: Follow-up enabled", it will update with the current position changes during homing.

- When the operation is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

- When MC\_Stop (Forced Stop) is executed

- When MC\_Stop (Forced Stop) is set to TRUE when homing, the "HALT" signal is sent to the drive unit. When using a drive unit that does not support HALT, use the forced stop signal because the drive unit does not stop with MC\_Stop (Forced Stop).
- Stop processing at homing depends on the specifications of the drive unit. Therefore, Deceleration (Deceleration) and Jerk (Jerk) of MC\_Stop (Forced Stop) are ignored.

## ■Data set homing method

Homing is executed for a virtual axis or a real axis that does not have the home position information in the device station side. The homing is completed in the Motion system, and external signals, etc. are not used. The Target position (Position) at homing is registered in the Motion system as the home position, and Command Current Position (AxisName.Md.SetPosition) and Cumulative Current Position (AxisName.Md.CumulativePosition) are rewritten to Target position (Position).

### • Timing chart

#### • Normal operation

#### • When the operation is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Homing request

- When it is necessary to execute homing, the Motion system changes Homing Request (AxisName.Md.Homing\_Request) to TRUE. Homing Request (AxisName.Md.Homing\_Request) becomes TRUE in the following cases.

- When the power supply of the system was turned on, or when a reset is performed.\*<sup>1</sup>
- When the axis type is changed.
- When homing is started. (The homing request flag will not become FALSE unless homing is completed successfully.)
- When axis driver unit conversion (numerator/denominator) is changed.
- When current position restoration is executed.
- When the absolute position data in the Motion system is erased because of a memory error or other cause.
- When the power supply of the drive unit is turned on.\*<sup>1</sup>\*<sup>2</sup>
- When "Absolute position erased" is detected on the drive unit side.\*<sup>2</sup>
- When "Polarity (607EH) (b7: position polarity)" of object data is changed\*<sup>2</sup>
- When the electronic gear is changed on the drive unit side.\*<sup>2</sup>
- When a drive unit or motor encoder change is detected.
- When it was detected that the absolute position in the scale measurement encoder is erased.\*<sup>3</sup>
- When the encoder resolution of the scale measurement encoder is changed.\*<sup>3</sup>
- When the upper limit value/lower limit value of the encoder ring counter is changed.\*<sup>4</sup>

\*<sup>1</sup> For an absolute position system, it does not become TRUE if homing is completed at reset or system/driver unit power off.

\*<sup>2</sup> Real drive axis only.

\*<sup>3</sup> Real encoder axis (via drive module) only.

\*<sup>4</sup> Virtual encoder axis only.

### Point

---

When Homing Request (AxisName.Md.Homing\_Request) becomes TRUE, it is recorded in the event history. The details can be checked in the event history.

---

- Execute a homing request clear in systems that do not require homing. Changing Homing Request Clear (AxisName.Cd.Homing\_ClearRequest) to TRUE causes Homing Request (AxisName.Md.Homing\_Request) to become FALSE.

### Point

---

Directly rewriting Homing Request (AxisName.Md.Homing\_Request) to FALSE with a program or others will not clear the homing request in the Motion system. Be sure to use Homing Request Clear (AxisName.Cd.Homing\_ClearRequest) to set the homing request to FALSE.

---

## ■Home position switch (AbsSwitch)

Sets the near-point dog signal that is transmitted to the device station in the driver homing method.

Home position switch (AbsSwitch) is set with an MC\_INPUT\_REF structure. For details on MC\_INPUT\_REF structures, refer to the following.

📖 Page 1487 MC\_INPUT\_REF

The setting range for Input signal (AbsSwitch.Signal) set in Home position switch (AbsSwitch) is shown below.

Trigger signal (TriggerInput.Signal) is SIGNAL\_SELECT structure type.

| Structure                     | Variable name                           | Type                                                       | Setting range                                                                                                                                                                                              |
|-------------------------------|-----------------------------------------|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                               | Detection (Signal detection method)     | INT<br>(MC_SIGNAL_LOGIC)<br>📖 Page 1524<br>MC_SIGNAL_LOGIC | <ul style="list-style-type: none"> <li>• 0: Detection at TRUE (HighLevel)</li> <li>• 1: Detection at FALSE (LowLevel)</li> </ul>                                                                           |
|                               | CompensationTime<br>(Compensation time) | LREAL                                                      | 0.0[s]                                                                                                                                                                                                     |
|                               | FilterTime (Filter time)                | LREAL                                                      | 0.0 to 5.0[s]                                                                                                                                                                                              |

- When [OBJ] is specified, if the target modification is omitted, the object set in the target axis specified by the operand axis (Axis) is referred. However, if the axis set to Axis (Axis) does not have a station address or a station address has not been set, External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H) will be output.
- When the station to be referred when [OBJ] is specified has the Axis Emulate function enabled and also has a set station address, the emulating object will be referred.
- When a signal that cannot be used for Signal name (AbsSwitch.Signal.Source.Target) is used, one of the following errors will be output: External signal selection string incorrect (error code: 1B05H), External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H), or Add-on Signal IO internal error (error code: 1B33H, 1BD8H).
- If a drive unit other than MELSERVO is specified as the axis, the signal specified by the home position switch cannot be transmitted as the dog signal to the drive unit.

### ■Options (Options)

The function options for MC\_Home (OPR) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". An error occurs if a value other than "0" is set.

| Bit | Name                                 | Description                                                                                                                                                                 |
|-----|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Follow-up enabled/disabled selection | Enables or disables the set position follow-up during driver homing. <ul style="list-style-type: none"><li>• 0: Follow-up disabled</li><li>• 1: Follow-up enabled</li></ul> |

### Precautions

- FBs other than MC\_Stop (Forced Stop) cannot start during homing.
- The software stroke limit check for the Target position (Position) at homing start is shown below.

| Homing method          | Description                                       |
|------------------------|---------------------------------------------------|
| Driver homing method   | The software stroke limit check is not performed. |
| Data set homing method | The software stroke limit check is performed.     |

- The software stroke limit check of the start position is not performed at homing start.
- The software stroke limit is not checked during homing.
- The movement direction at homing completion is in the positive direction.

## ■Precautions for the driver homing method

- The homing cannot be started during servo OFF. Thus, the drive unit homing methods (Homing method35, 37 (Data set method)) cannot be executed during servo OFF.
- When the external signals (the hardware stroke limit specified with axis variables and the proximity dog specified with Home position switch (AbsSwitch)) are assigned, the external signals are transmitted to the drive unit. However, when the position accuracy is required in the proximity dog based (not Z-phase based) method, using the built-in DI in the drive unit is recommended.
- When Follow-up enabled/disabled selection (Options (Options): Bit 16) is set to "0: Follow-up disabled", the set position is not followed up during homing with the driver homing method. In this case, do not execute synchronous control by setting the axis that is in homing as the master axis. Doing this may cause a Velocity Range Over during Controlling (error code: 1B1AH) to occur in the slave axis.
- When Follow-up enabled/disabled selection (Options (Options): Bit 16) is set to "1: Follow-up enabled", and synchronous control is executed by setting the axis that is in homing as the master axis, the slave axis operations depending on the master axis data source selection are shown below.

| Master axis data source selection<br>(MasterValueSource)                          | Slave axis operation during synchronous control                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1: Set value (mcSetValue) 101: Latest set value (mcLatestSetValue)                | Synchronous control continues even after homing completes.                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2: Actual value (mcActualValue)<br>102: Latest actual value (mcLatestActualValue) | Although the slave axis synchronizes with the master axis until homing completion, an error or alarm may occur on the drive unit side by reasons of sudden motor acceleration or an excessive command input because synchronous control is not achieved at the end. For details, refer to the manual for each drive unit.<br>For the MR-J5, the servo alarm [AL. 031.1_Servo motor speed error] or the servo alarm [AL. 035.1_Command frequency error] may occur. |

- When Homing Operation Status (AxisName.Md.Homing\_Status) is "0002H: Homing attained (target not reached)", and a stop cause occurs, the set position that has been followed up changes significantly. Therefore, an error or servo alarm may occur on the drive unit side even if "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" is selected in Master axis data source selection (MasterValueSource). For details, refer to the manual for each drive unit.  
Example: For the MR-J5, the servo alarm ([AL.031.1 (Servo motor speed error)] or [AL. 035.1 (Command frequency error)]) may occur.
- If the following object data items are not mapped, backup is not guaranteed.

Home cycle counter (2D3DH)

Home ABS counter (2D3EH)

- The DOG signal that has been input in the servo amplifier at MR-J5(W)-G connection can be specified as the home position switch signal. For details on the setting method, refer to the following.

 User's manual for the controller used

- If the hardware stroke limit signal is detected during homing, the "HALT" signal is sent to the drive unit. To stop the operation using the limit switch signal on the drive unit side, set Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit\_Override) to "DISABLE (Check disabled)" and temporarily disable the hardware stroke limit check.
- If Hardware stroke limit override (AxisName.Cd.HwStrokeLimit\_Override) is set to "ONLY\_INSIDE (Check disabled only to inside the range direction)", Start Not Possible (error code: 1AFCH) occurs and homing is not performed.

## Program example

The following is a program example. The homing command (bHomingCMD) is set to TRUE, and homing is performed for Axis 1 (Axis0001) with Home position switch "[DEV](BOOL)D0".

### Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### Labels used

| Label name      | Data type                           | Comment               |
|-----------------|-------------------------------------|-----------------------|
| MC_Home_1       | MC_Home                             | OPR FB                |
| bHomingCMD      | Bit                                 | Homing command        |
| InputRef        | MC_INPUT_REF                        | Home position switch  |
| bDone           | Bit                                 | Execution completion  |

## Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                 |
|-----------------|-----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the velocity reaches 0.                                                                                                     |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MC_Stop (Forced Stop) is executed.                                                                                          |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MC_Stop (Forced Stop) is controlling the axis.                                                                             |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_Stop (Forced Stop) is aborted.                                                                              |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- This FB sets Deceleration (Deceleration) and decelerates the under-control FB to a stop.
- When MC\_Stop (Forced Stop) is executed, Abortion of execution (CommandAborted) becomes TRUE for the FB being executed and Axis status (AxisName.Md.AxisStatus) transits to "2: Decelerating to Stop (Stopping)". While Execution command (Execute) is TRUE or if the velocity has not reached "0.0", "2: Decelerating to Stop (Stopping)" is maintained. When Execution completion (Done) becomes TRUE and Execution command (Execute) becomes FALSE at stop completion, the axis status changes to "4: Standby (Standstill)".

## Timing chart

- When the processing is completed successfully

When MC\_Stop (Forced Stop) is executed during MCv\_SpeedControl (Speed Control (Including Position Loop))

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ Operation overview

- When input variable Execution command (Execute) is TRUE during deceleration stop with MC\_Stop (Forced Stop), operation commands other than MC\_Stop (Forced Stop) are not accepted.
- If Deceleration (Deceleration) is set to "0.0" or omitted, immediate stop will be executed.
- The acceleration/deceleration method and the jerk take over the method specified in the on-going control and decelerate.
- If MC\_GroupStop (Group Forced Stop) is executed during single axis synchronous control, synchronization to the master axis will be canceled.
- When the setting value of Deceleration (Deceleration) is changed and MC\_Stop (Forced Stop) is restarted, the deceleration stop is executed from the restart point based on the value of Deceleration (Deceleration) in MC\_Stop (Forced Stop).

- When an FB that operates axes other than MC\_Stop (Forced Stop) is executed while Axis status (AxisName.Md.AxisStatus) is set to "2: Decelerating to Stop (Stopping)", Start Not Possible (error code: 1AFCH) occurs and Error (Error) becomes TRUE for MC\_Stop (Forced Stop) and Axis status (AxisName.Md.AxisStatus) changes to "1: Stopping on Error (ErrorStop)".
- After the axis stops, the axis status can be transitioned to "4: Standby (Standstill)" by executing Axis Error Reset (AxisName.Cd.ErrorReset).

- Even if MC\_Stop (Forced Stop) is used to set Execution command (Execute) to FALSE for the FB whose execution was aborted, once the stop operation starts, Abortion of execution (CommandAborted) remains TRUE until the stop is completed. After the stop completes, Abortion of execution (CommandAborted) becomes FALSE if Execution command (Execute) is FALSE for the FB whose execution was aborted.

## Program example

The following is a program example. The axis stop request (bStop) is set to TRUE, and Axis 1 (Axis0001) is decelerated to a stop at a deceleration of "100000.0".

### Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### Labels used

| Label name      | Data type                           | Comment               |
|-----------------|-------------------------------------|-----------------------|
| MC_Stop_1       | MC_Stop                             | Forced Stop FB        |

## ■Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                 |
|-----------------|-----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the velocity reaches 0.                                                                                                     |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when operating the velocity toward 0.                                                                                            |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MC_GroupStop (Group Forced Stop) is controlling the axes.                                                                  |
| Command Aborted | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_GroupStop (Group Forced Stop) is aborted.                                                                   |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                            |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used |

## Processing details

- This FB sets Deceleration (Deceleration) and decelerates the under-control FB to a stop. The axes group passes through the previous operation path and decelerates to a stop.
- When MC\_GroupStop (Group Forced Stop) is executed, Abortion of execution (CommandAborted) of the FB being executed becomes TRUE and Axes group status (AxesGroupName.Md.GroupStatus) transits to "2: Decelerating to Stop (GroupStopping)". While Execution command (Execute) is TRUE or if the velocity has not reached "0.0", "2: Decelerating to Stop (GroupStopping)" is maintained. When Execution completion (Done) becomes TRUE and Execution command (Execute) becomes FALSE at stop completion, the axis group status changes to "4: Standby (GroupStandby)".

## ■Timing chart

- When the processing is completed successfully

When MC\_GroupStop (Group Forced Stop) is executed during MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control)

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ Operation overview

- When input variable Execution command (Execute) is TRUE during deceleration stop with MC\_GroupStop (Group Forced Stop), operation commands other than MC\_GroupStop (Group Forced Stop) are not accepted.
- If Deceleration (Deceleration) is set to "0.0" or omitted, immediate stop will be executed.
- The acceleration/deceleration method and the jerk take over the method specified in the on-going control and decelerate.
- When the setting value of Deceleration (Deceleration) is changed and MC\_GroupStop (Group Forced Stop) is restarted, the deceleration stop is executed from the restart point based on the value of Deceleration (Deceleration) in MC\_GroupStop (Group Forced Stop) and Jerk (Jerk) of the under-control FB.

- When an FB that operates axes other than MC\_GroupStop (Group Forced Stop) is executed while Axes group status (AxesGroupName.Md.GroupStatus) is set to "2: Decelerating to Stop (GroupStopping)", Start Not Possible (error code: 1AFCH) occurs and Error (Error) becomes TRUE for MC\_GroupStop (Group Forced Stop) and Axes group status (AxesGroupName.Md.GroupStatus) changes to "1: Stopping on Error (GroupErrorStop)".
- Even if MC\_GroupStop (Group Forced Stop) is used to set Execution command (Execute) to FALSE for the FB whose execution was aborted, once the stop operation starts, Abortion of execution (CommandAborted) remains TRUE until the stop is completed. After the stop completes, Abortion of execution (CommandAborted) becomes FALSE if Execution command (Execute) is FALSE for the FB whose execution was aborted.

## Program example

The following is a program example. The axes group stop request (bGroupStop) is set to TRUE, and Axes group 1 (AxesGroup001) is decelerated to a stop at a deceleration of "100000.0".

### ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

### ■Labels used

| Label name      | Data type                           | Comment                 |
|-----------------|-------------------------------------|-------------------------|
| MC_GroupStop_1  | MC_GroupStop                        | Axes group stop FB      |
| bGroupStop      | Bit                                 | Axes group stop request |
| leDeceleration  | Double-precision real number        | Deceleration            |
| leJerk          | Double-precision real number        | Jerk                    |
| bDone           | Bit                                 | Completion              |
| bBusy           | Bit                                 | Executing               |
| bActive         | Bit                                 | Controlling             |
| bCommandAborted | Bit                                 | Abortion of execution   |
| bError          | Bit                                 | Error                   |
| uwErrorID       | Word [unsigned]/bit string [16-bit] | Error code              |

## ■ Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                     |
|-----------------|-----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the target position is reached.                                                                                                                                                                                 |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MC_MoveAbsolute (Absolute Value Positioning) is being executed.<br>This variable becomes FALSE after the target position is reached.                                                                            |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MC_MoveAbsolute (Absolute Value Positioning) is controlling the axis.<br>This variable becomes FALSE after the target position is reached.                                                                     |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_MoveAbsolute (Absolute Value Positioning) is aborted.<br>The variable becomes FALSE when Execution command (Execute) becomes FALSE.                                                             |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

- This FB sets Target position (Position), Velocity (Velocity), Acceleration (Acceleration), Deceleration (Deceleration), Jerk (Jerk), Direction selection (Direction), Buffer mode (BufferMode), and Options (Options), and executes positioning from the current position at start (start point position) to the specified position (end point position) set in Target position (Position).

### Ex.

When the start point position (current stop position) is "1000.0" and Target position (Position) is set to "8000.0"

- Positioning is performed in the positive direction for a movement amount of "7000.0 (8000.0 - 1000.0)"

### ■ Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Target position (Position)

Sets the target position of the absolute position. The valid range differs depending on whether the software stroke limit is valid/invalid, Direction selection (Direction), and the setting for Target position specification exceeding the ring counter (Options (Options): Bit 16).

- When the software stroke limit is valid (when Software stroke limit target (AxisName.Md.SwStrokeLimit\_Target) is set to a value other than "-1: Invalid (Invalid)")

The valid range is as follows regardless of Direction selection (Direction) and the setting for Target position specification exceeding the ring counter (Options (Options): Bit 16).

| Valid range                                                                       |
|-----------------------------------------------------------------------------------|
| Ring counter lower limit value ≤ Target position < Ring counter upper limit value |

If a value outside the range is set, Out of Target Position Range (error code: 1A85H) occurs and the axis will not start. In addition, even when the value set is within the valid range, Software Stroke Limit Over (Target Position) (error code: 1A80H) occurs and the axis will not start if a position which exceeds the software stroke limit is specified as the target position.

- When the software stroke limit is invalid (when Software stroke limit target (AxisName.Md.SwStrokeLimit\_Target) is set to "-1: Invalid (Invalid)")

Setting "Target position specification exceeding the ring counter (Options (Options): Bit 16)" to "1: Allow" allows execution of positioning that exceeds the ring counter range by one revolution or more.

If a value outside the range is set, Out of Target Position Range (error code: 1A85H) occurs and the axis will not start.

| Direction selection (Direction)             | Target position specification exceeding the ring counter (Options (Options): Bit 16) | Valid range                                                                            |
|---------------------------------------------|--------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 1: Positive direction (mcPositiveDirection) | 0: Disabled                                                                          | Ring counter lower limit value ≤ Target position < Ring counter upper limit value      |
|                                             | 1: Enabled                                                                           | Ring counter lower limit value ≤ Target position < Positioning range upper limit value |
| 2: Negative direction (mcNegativeDirection) | 0: Disabled                                                                          | Ring counter lower limit value ≤ Target position < Ring counter upper limit value      |
|                                             | 1: Enabled                                                                           | Positioning range lower limit value ≤ Target position < Ring counter upper limit value |
| 3: Shortest path (mcShortestWay)            | 0: Disabled                                                                          | Ring counter lower limit value ≤ Target position < Ring counter upper limit value      |
|                                             | 1: Enabled                                                                           | Ring counter lower limit value ≤ Target position < Ring counter upper limit value      |

- For the direction used to move to the target position, refer to the following.

📖 Page 1674 Direction selection (Direction)

## ■Velocity (Velocity)

Sets the command velocity used in MC\_MoveAbsolute (Absolute Value Positioning).

| Setting range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 0.0, 0.0001 to 2500000000.0 <sup>*1</sup> <sup>*2</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <p>*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.<br/>If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (<u>AxisName</u>.Pr.Unit_Position) and Speed command unit (<u>AxisName</u>.Pr.Unit_Velocity) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".</p> <p>*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.</p> |

## ■Acceleration (Acceleration)

Sets the acceleration used in MC\_MoveAbsolute (Absolute Value Positioning).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 2) | Setting range                                                                           |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0 [U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method<br>(mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                    |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MC\_MoveAbsolute (Absolute Value Positioning).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 2) | Setting range                                                                           |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0 [U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method<br>(mcFixedTime)             | Not used                                                                                |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MC\_MoveAbsolute (Absolute Value Positioning).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 2) | Setting range                                                            |
|-----------------------------------------------------------------------------|--------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0 [U/s <sup>3</sup> ] |
| 1: Acceleration/deceleration time-fixed method<br>(mcFixedTime)             | Not used                                                                 |

## ■Direction selection (Direction)

The setting for Direction selection (Direction) is ignored when the software stroke limit is valid. Positioning control is performed in a direction which does not cross over into the area outside the software stroke limit range. If the value does not cross over into the area outside the software stroke limit range in either the positive direction or the negative direction, positioning control is performed in the direction closest to the target position (the direction in which the absolute value of the movement amount is shortest) based on the current position. If the distance is the same in both the positive direction and the negative direction, control is performed using the current direction.

When the software stroke limit is invalid, the direction used to move from the current position to the target position can be set by selecting from "1: Positive direction (mcPositiveDirection)", "2: Negative direction (mcNegativeDirection)", or "3: Shortest path (mcShortestWay)" in Direction selection (Direction).

- 1: Positive direction (mcPositiveDirection)

Performs positioning from the current position to the target position in the positive direction (address increasing).

| Target position specification exceeding the ring counter (Options): Bit 16                                                                                                                                                                                                                                                                                                                                                                                                        | Setting range                                                                                                                        | Operation |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------|
| <b>■0: Disabled</b><br>The setting range of the target position is "Ring counter lower limit value ≤ Target position < Ring counter upper limit value".                                                                                                                                                                                                                                                                                                                           | Current value ≤ Target position < Ring counter upper limit value                                                                     |           |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Ring counter lower limit value ≤ Target position < Current value                                                                     |           |
| <b>■1: Enabled</b><br>Allows positioning operation that overflows the ring counter upper limit value to be performed. For this setting, the ring counter upper limit value is used as a reference to perform positioning using the amount of movement exceeded as the relative movement amount. If the target position is set to a value smaller than the ring counter lower limit value, positioning does not start and Out of Target Position Range (error code: 1A85H) occurs. | Current value ≤ Target position < Ring counter upper limit value<br>Ring counter lower limit value ≤ Target position < Current value |           |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Ring counter upper limit value ≤ Target position < Positioning range upper limit value                                               |           |

**Ex.**

Operation when set to the values shown below (performs relative value positioning after exceeding the ring counter upper limit value).

- Ring counter upper limit value: 100.0
- Ring counter lower limit value: -50.0
- Current position: 30.0
- Target position: 350.0

- 2: Negative direction (mcNegativeDirection)

Performs positioning in the negative direction (address decreasing) from the current position to the target position.

| Target position specification exceeding the ring counter (Options (Options): Bit 16)                                                                   | Setting range                                                    | Operation |

#### Ex.

Operation when set to the values shown below

- Operation when set to the values shown below
- Ring counter upper limit value: 100.0
- Ring counter lower limit value: -50.0
- Current position: -20.0
- Target position: -220.0

- 3: Shortest path (mcShortestWay)

Based on the current position, positioning control is performed in the direction closest to the target position (the direction in which the absolute value of the movement amount is shortest). If the distance is the same in both the positive direction and the negative direction, control is performed using the current direction. Regardless of the setting for Target position specification exceeding the ring counter (Options (Options): Bit 16), the setting range for the target position is "Ring counter lower limit value ≤ Target position < Ring counter upper limit value". If a value outside the range is set, Out of Target Position Range (error code: 1A85H) occurs and the axis will not start.

#### Ex.

Operation when set to the values shown below

- Ring counter upper limit value: 100.0
- Ring counter lower limit value: -100.0
- Current position: 80.0
- Target position: -80.0

Ring counter  
upper limit value: 100.0  
Current value: 80.0

Target position: -80.0  
Ring counter  
lower limit value: -100.0

\*1 Since the movement amount of (1) is "160.0" and the movement amount of (2) is "40.0", positioning moves in the positive direction from (2).

### ■ Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MC\_MoveAbsolute (Absolute Value Positioning).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                              |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                        |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*1 Stops are not performed between the under-control FB and the buffering FB.

#### Point

For details on multiple start (buffer mode), refer to the following.

📖 User's manual for the controller used

## Options (Options)

The function options for MC\_MoveAbsolute (Absolute Value Positioning) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                                     | Description                                                                                                                                                                                                                                                                                                                                       |
|--------|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/deceleration method setting                 | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"> <li>0: Acceleration/deceleration specification method (mcAccDec)</li> <li>1: Acceleration/deceleration time-fixed method (mcFixedTime)</li> </ul>                                                                                           |
| 5      | Reverse rotation permission selection                    | Sets whether to allow reverse rotation when the operation direction of the FB being executed and the buffering FB are different. <ul style="list-style-type: none"> <li>0: Enabled</li> <li>1: Disabled</li> </ul> *: This bit is valid when switching to the subsequent buffering FB during axis operation or when changing the target position. |
| 16     | Target position specification exceeding the ring counter | Sets whether to allow a target position that exceeds the ring counter upper limit value or lower limit value when the software stroke limit is invalid. <ul style="list-style-type: none"> <li>0: Disabled</li> <li>1: Enabled</li> </ul>                                                                                                         |

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                | Description                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MC_MoveAbsolute (Absolute Value Positioning).                                                                                                                         |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MC_MoveAbsolute (Absolute Value Positioning) regardless of the velocity.<br>The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

### • Reverse rotation permission selection (Bit 5)

| Setting value | Description                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Enabled    | Allows reverse rotation.<br>Performs a deceleration stop once, then starts operation to the changed direction once the deceleration stop is completed. |
| 1: Disabled   | Does not allow reverse rotation.<br>When switched, Overrun Error (error code: 1AE3H) occurs and a deceleration stop is performed.                      |

## Necessary object data

When using MC\_MoveAbsolute (Absolute Value Positioning), set the following object data for the axis.

- Target position (607AH)

If the object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

User's manual for the controller used

## Program example

The following is a program example. The single axis absolute value positioning start (bMoveAbsolute) is set to TRUE, and absolute positioning control is performed for Axis 1 (Axis0001).

- Operation

- Settings

| Item            | Setting value |
|-----------------|---------------|
| Target position | 80000.0       |
| Velocity        | 50000.0       |
| Acceleration    | 100000.0      |
| Deceleration    | 100000.0      |
| Jerk            | 0.0           |

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name        | Data type                           | Comment                                      |
|-------------------|-------------------------------------|----------------------------------------------|
| MC_MoveAbsolute_1 | MC_MoveAbsolute                     | Absolute Value Positioning FB                |
| bMoveAbsolute     | Bit                                 | Single axis absolute value positioning start |
| lePosition        | Double-precision real number        | Target position                              |
| leVelocity        | Double-precision real number        | Velocity                                     |
| leAcceleration    | Double-precision real number        | Acceleration                                 |
| leDeceleration    | Double-precision real number        | Deceleration                                 |
| leJerk            | Double-precision real number        | Jerk                                         |
| bDone             | Bit                                 | Execution completion                         |
| bBusy             | Bit                                 | Executing                                    |
| bActive           | Bit                                 | Controlling                                  |
| bCommandAborted   | Bit                                 | Abortion of execution                        |
| bError            | Bit                                 | Error                                        |
| uwErrorID         | Word [unsigned]/bit string [16-bit] | Error code                                   |

# 46.5 Relative Value Positioning

## MC\_MoveRelative

This FB sets the movement amount of the relative position and performs positioning.

| Ladder | FBD/LD | ST                                                                                                                                                                                                                                                                                                                                                                                                                        |

| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_MoveRelative (Relative Value Positioning) is aborted.<br>The variable becomes FALSE when Execution command (Execute) becomes FALSE.                                                             |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

- This FB sets Movement amount (Distance), Velocity (Velocity), Acceleration (Acceleration), Deceleration (Deceleration), Jerk (Jerk), and Buffer mode (BufferMode), and executes positioning from the current position at start (start point position) using the movement amount set in Movement amount (Distance). The movement direction is determined by the sign of the movement amount. Axis status (AxisName.Md.AxisStatus) becomes "5: During positioning operation (DiscreteMotion)".

### Ex.

When the start point position (current stop position) is "5000.0" and the movement amount is set to "-7000.0"

- Positioning is performed to "-2000.0".

## Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## Movement amount (Distance)

This variable sets the movement amount from the current position at start to the end point.

The movement direction is determined by the sign (+/-) of the movement amount.

| Movement amount | Description                                                     |
|-----------------|-----------------------------------------------------------------|
| If positive (+) | Moves in the positive direction (address increasing direction). |
| If negative (-) | Moves in the negative direction (address decreasing direction). |

When the movement amount is "0", the axis is not operated but Execution completion (Done) becomes TRUE.

If the set movement amount is outside the range, Out of Target Position Range (error code: 1A85H) occurs and the operation will not start.

If "current value + movement amount" overflows the software stroke limit upper limit value or software stroke limit lower limit value when the software stroke limit is valid, Software Stroke Limit Over (target position) (error code: 1A80H) will occur and the operation will not start.

## ■Velocity (Velocity)

Sets the command velocity used in MC\_MoveRelative (Relative Value Positioning).

| Setting range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0.0, 0.0001 to 2500000000.0 <sup>*1</sup> 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <p>*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.<br/>If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (<a href="#">AxisName.Pr.Unit_Position</a>) and Speed command unit (<a href="#">AxisName.Pr.Unit_Velocity</a>) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".</p> <p>*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.</p> |

## ■Acceleration (Acceleration)

Sets the acceleration used in MC\_MoveRelative (Relative Value Positioning).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 ([AxisName.Pr.AccelerationZeroBehavior](#)). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MC\_MoveRelative (Relative Value Positioning).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 ([AxisName.Pr.AccelerationZeroBehavior](#)). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MC\_MoveRelative (Relative Value Positioning).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■ Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MC\_MoveRelative (Relative Value Positioning).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                              |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                        |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*1 Stops are not performed between the under-control FB and the buffering FB.

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

## Options (Options)

The function options for MC\_MoveRelative (Relative Value Positioning) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                     | Description                                                                                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/deceleration method setting | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"> <li>0: Acceleration/deceleration specification method (mcAccDec)</li> <li>1: Acceleration/deceleration time-fixed method (mcFixedTime)</li> </ul>                                                                                                  |
| 3      | Position selection during buffer mode    | Sets the position when executing relative positioning control by multiple start. <ul style="list-style-type: none"> <li>0: Set position</li> <li>1: Actual position</li> </ul> <p>* This bit is valid when setting "0: Aborting (mcAborting)" in Buffer mode (BufferMode).</p>                                                                           |
| 5      | Reverse rotation permission selection    | Sets whether to allow reverse rotation when the operation direction of the FB being executed and the buffering FB are different. <ul style="list-style-type: none"> <li>0: Enabled</li> <li>1: Disabled</li> </ul> <p>*: This bit is valid when switching to the subsequent buffering FB during axis operation or when changing the target position.</p> |

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                | Description                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MC_MoveRelative (Relative Value Positioning).                                                                                                                      |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MC_MoveRelative (Relative Value Positioning) regardless of the velocity. The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

### • Position selection during buffer mode (Bit 3)

| Setting value      | Description                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Set position    | <p>Performs relative positioning control from the set position.</p> <p>&lt;Example&gt;</p> <p>When multiple start is performed with Movement amount (Distance) set to "5000.0" and Options (Options) set to "00000000H (Bit 3 is 0: Set position)"</p> <p>The position moves only the movement amount (Distance) according to the set position.</p>           |
| 1: Actual position | <p>Performs relative positioning control from the actual position.</p> <p>&lt;Example&gt;</p> <p>When multiple start is performed with Movement amount (Distance) set to "5000.0" and Options (Options) set to "00000008H (Bit 3 is 1: Actual position)".</p> <p>The position moves only the movement amount (Distance) according to the actual position.</p> |

- Reverse rotation permission selection (Bit 5)

| Setting value | Description                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Enabled    | Allows reverse rotation.<br>Performs a deceleration stop once, then starts operation to the changed direction once the deceleration stop is completed. |
| 1: Disabled   | Does not allow reverse rotation.<br>When switched, Overrun Error (error code: 1AE3H) occurs and a deceleration stop is performed.                      |

## ■ Necessary object data

When using MC\_MoveRelative (Relative Value Positioning), set the following object data for the axis.

- Target position (607AH)

If the object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

 User's manual for the controller used

## Precautions

- The current position where MC\_MoveRelative (Relative Value Positioning) was started for the first time is used as the start address even if a restart/continuous update is performed.
- Since floating point type processing is used, if relative positioning control is repeatedly executed, the set movement amount may not be reached due to a calculation error.

## Program example

The following is a program example. The single axis relative value positioning start (bMoveRelative) is set to TRUE, and relative positioning control is performed for Axis 1 (Axis0001).

### • Operation

### • Settings

| Item            | Setting value |
|-----------------|---------------|
| Target position | 80000.0       |
| Velocity        | 50000.0       |
| Acceleration    | 100000.0      |
| Deceleration    | 100000.0      |
| Jerk            | 0.0           |

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name        | Data type                           | Comment                                      |
|-------------------|-------------------------------------|----------------------------------------------|
| MC_MoveRelative_1 | MC_MoveRelative                     | Relative Value Positioning FB                |
| bMoveRelative     | Bit                                 | Single axis relative value positioning start |
| leDistance        | Double-precision real number        | Movement amount                              |
| leVelocity        | Double-precision real number        | Velocity                                     |
| leAcceleration    | Double-precision real number        | Acceleration                                 |
| leDeceleration    | Double-precision real number        | Deceleration                                 |
| leJerk            | Double-precision real number        | Jerk                                         |
| bDone             | Bit                                 | Execution completion                         |
| bBusy             | Bit                                 | Executing                                    |
| bActive           | Bit                                 | Controlling                                  |
| bCommandAborted   | Bit                                 | Abortion of execution                        |
| bError            | Bit                                 | Error                                        |
| uwErrorID         | Word [unsigned]/bit string [16-bit] | Error code                                   |

## ■ Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                     |
|-----------------|-----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE only for one scan when a deceleration stop is completed by turning off the JOG command.                                                                                                                              |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MCv_Jog (JOG) is executed.                                                                                                                                                                                      |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MCv_Jog (JOG) is controlling the axis.                                                                                                                                                                         |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MCv_Jog (JOG) is aborted.                                                                                                                                                                          |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

- This FB moves the target axis to the specified direction when Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) is set to TRUE.
- Axis status (AxisName.Md.AxisStatus) is "6: During continuous operation (ContinuousMotion)" during JOG operation.
- A deceleration stop is performed when Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) is set to FALSE.
- Axis status (AxisName.Md.AxisStatus) changes to "4: Standby (Standstill)" at deceleration stop completion.
- If Error (Error) becomes TRUE during deceleration by Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) becoming FALSE, Error (Error) remains TRUE until Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) is set to TRUE.
- When another operation FB is started during JOG operation, the operation is performed based on the setting of Buffer mode (BufferMode) of the started operation FB.
- When JOG operation is started during another operation FB, the start request is ignored and Start during Operation Warning (event code: 00D01H) occurs. Start JOG operation when Axis status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)".
- To change the velocity during JOG operation, use the override function to perform the velocity change. For details on the override function, refer to the following.

 User's manual for the controller used

### ■ Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

## ■ Positive rotation JOG command (JogForward)/Reverse rotation JOG command (JogBackward)

- Setting Positive rotation JOG command (JogForward) to TRUE starts positive rotation JOG operation, and setting Reverse rotation JOG command (JogBackward) to TRUE starts reverse rotation JOG operation, following which the target axis moves in the specified direction.
- If Positive rotation JOG command (JogForward) and Reverse rotation JOG command (JogBackward) are set to TRUE simultaneously, JOG Command Input at Both Directions Warning (event code: 00D02H) occurs, Abortion of execution (CommandAborted) becomes TRUE, and JOG operation will not start. To perform JOG operation, first set the JOG commands for both directions to FALSE and wait for Abortion of execution (CommandAborted) to become FALSE, then set either Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) to TRUE.
- During JOG operation, if the other JOG command (Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward)) of MCv\_JOG (JOG) becomes TRUE, JOG Command Input at Both Directions Warning (event code: 00D02H) occurs and a deceleration stop is performed from the point where the said TRUE was detected. When performing JOG operation, only set either Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) to TRUE. To perform JOG operation, only one of Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) must be set to TRUE.

- During the deceleration stop by Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) becoming FALSE, re-acceleration will not be performed even if the JOG command is set to TRUE. The acceleration will be performed after the deceleration stop is completed.

- To repeatedly perform deceleration stop and acceleration while moving by JOG operation, use the override function to perform the velocity change.

### ■Velocity (Velocity)

Sets the command velocity used in MCv\_Jog (JOG).

The settings are imported when JOG operation is started by Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) becoming TRUE. Changes made during JOG operation are not accepted.

| Setting range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0.0, 0.0001 to 2500000000.0 <sup>*1,2</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p>*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.<br/>If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (<u>AxisName.Pr.Unit_Position</u>) and Speed command unit (<u>AxisName.Pr.Unit_Velocity</u>) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".</p> <p>*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.</p> |

### ■Acceleration (Acceleration)

Sets the acceleration used in MCv\_Jog (JOG).

The settings are imported when JOG operation is started by Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) becoming TRUE. Changes made during JOG operation are not accepted.

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MCv\_Jog (JOG).

The settings are imported when JOG operation is started by Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) becoming TRUE. Changes made during JOG operation are not accepted.

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MCv\_Jog (JOG).

The settings are imported when JOG operation is started by Positive rotation JOG command (JogForward) or Reverse rotation JOG command (JogBackward) becoming TRUE. Changes made during JOG operation are not accepted.

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Options (Options)

The function options for MCv\_Jog (JOG) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                     | Description                                                                                                                                                                                            |
|--------|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/deceleration method setting | Sets the acceleration/deceleration method used to perform control.<br>• 0: Acceleration/deceleration specification method (mcAccDec)<br>• 1: Acceleration/deceleration time-fixed method (mcFixedTime) |

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                | Description                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MCv_Jog (JOG).                                                                                                                         |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MCv_Jog (JOG) regardless of the velocity.<br>The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

## ■Necessary object data

When using MCv\_Jog (JOG Operation), set the following object data for the axis.

- Target position (607AH)

If the object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

📖 User's manual for the controller used

## Precautions

- For safety, first set a small value in Velocity (Velocity) and check the movement, then gradually increase the value.
- Use the hardware stroke limit function when performing JOG operation near the upper limit or lower limit. If the hardware stroke limit function is not used, the workpiece may exceed the moving range and cause an accident.
- When the software stroke limit function is valid and Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit\_Override) is other than DISABLE (Check disabled) or ONLY\_INSIDE (Check disabled only for movement returning to the range), Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit\_Override) is rewritten into ONLY\_INSIDE (Check disabled only for movement returning to the range) during MCv\_Jog (JOG Operation) execution, and it is rewritten into a blank at JOG operation completion.
- When the hardware stroke limit function is valid and Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit\_Override) is other than DISABLE (Check disabled) or ONLY\_INSIDE (Check disabled only for movement returning to the range), Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit\_Override) is rewritten into ONLY\_INSIDE (Check disabled only for movement returning to the range) during MCv\_Jog (JOG Operation) execution, and it is rewritten into a blank at JOG operation completion.
- Do not change Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit\_Override) and Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit\_Override) during MCv\_Jog (JOG) execution.
- When multiple start is executed during JOG operation, the values of Software Stroke Limit Override (AxisName.Cd.SwStrokeLimit\_Override) and Hardware Stroke Limit Override (AxisName.Cd.HwStrokeLimit\_Override) at the multiple start are retained to the next FB to analyze the next FB.
- When the movement is executed in the opposite direction from that at start after a deceleration stop is performed during JOG operation, and if the command velocity exceeds the velocity limit value, Velocity Limit Value Over Warning on Direction Change (event code: 00D20H) occurs. In addition, when the acceleration time exceeds 8400 seconds, Acceleration Time Over Warning on Direction Change (event code: 00D32H) occurs. (The operation continues at velocity 0.) Movement starts after changing control to remove the cause.

### Ex.

When the following values are set

- Positive Direction Speed Limit Value (AxisName.Pr.VelocityLimit\_Positive): 2000.0
- Negative Direction Speed Limit Value (AxisName.Pr.VelocityLimit\_Negative): 1000.0

## Program example

The following is a program example. The JOG positive rotation command (bJogForward) is set to TRUE for positive rotation JOG operation and the JOG reverse rotation command (bJogBackward) is set to TRUE for reverse rotation JOG operation. Then, JOG operation is performed for Axis 1 (Axis0001).

- Setting

| Item         | Setting value |
|--------------|---------------|
| Velocity     | 1500.0        |
| Acceleration | 2000.0        |
| Deceleration | 2000.0        |
| Jerk         | 0.0           |

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name        | Data type                           | Comment                       |

## ■ Output variables

| Output variable | Name                          | Data type  | Default value | Description                                                                                                                                                                                                                                                                                                        |
|-----------------|-------------------------------|------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| InVelocity      | Target<br>velocity<br>reached | BOOL       | FALSE         | This variable becomes TRUE when the command velocity calculated by the Motion system reaches the target velocity.<br>When the target velocity has been changed due to change at Continuous update (ContinuousUpdate) TRUE, this variable remains FALSE until the velocity reaches the post-change target velocity. |
| Busy            | Executing                     | BOOL       | FALSE         | This variable becomes TRUE when MC_MoveVelocity (Speed Control) is executed.                                                                                                                                                                                                                                       |
| Active          | Controlling                   | BOOL       | FALSE         | This variable becomes TRUE while MC_MoveVelocity (Speed Control) is controlling the axis.                                                                                                                                                                                                                          |
| CommandAborted  | Abortion of<br>execution      | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_MoveVelocity (Speed Control) is aborted.<br>The variable becomes FALSE when Execution command (Execute) becomes FALSE.                                                                                                                                             |
| Error           | Error                         | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                                                                                   |
| ErrorID         | Error code                    | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used                                                                                                                                                        |

## Processing details

MC\_MoveVelocity (Velocity Control) switches the drive unit control mode to csv and performs control. This function controls the command velocity based on the set Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). To finish MC\_MoveVelocity (Speed Control), start MC\_Stop (Forced Stop).

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

### ■Velocity (Velocity)

Sets the command velocity used in MC\_MoveVelocity (Speed Control).

#### Setting range

0.0,  $\pm 0.0001$  to  $\pm 25000000000.0^{*1*2}$

- \*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.  
If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (AxisName.Pr.Unit\_Position) and Speed command unit (AxisName.Pr.Unit\_Velocity) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".
- \*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.

## ■Acceleration (Acceleration)

Sets the acceleration used in MC\_MoveVelocity (Speed Control).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MC\_MoveVelocity (Speed Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MC\_MoveVelocity (Speed Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MC\_MoveVelocity (Speed Control).

| Setting value            | Description                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                       |
| 1: Buffered (mcBuffered) | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB. |

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

## ■Options (Options)

The function options for MC\_MoveVelocity (Speed Control) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                     | Description                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/deceleration method setting | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"> <li>0: Acceleration/deceleration specification method (mcAccDec)</li> <li>1: Acceleration/deceleration time-fixed method (mcFixedTime)</li> </ul>                                        |
| 16, 17 | Velocity initial value selection         | The velocity initial value used when changing the control mode from cyclic synchronous position mode (csp) to cyclic synchronous velocity mode (csv) is set. <ul style="list-style-type: none"> <li>0: Command velocity</li> <li>1: Actual velocity</li> <li>2: Automatic selection</li> </ul> |

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                | Description                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MC_MoveVelocity (Speed Control)                                                                                                                          |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MC_MoveVelocity (Speed Control) regardless of the velocity.<br>The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

### • Velocity initial value selection (Bit 16, 17)

| Setting value          | Description                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Command velocity    | The velocity during command is used as the velocity commanded to the drive unit immediately after switching.                                                 |
| 1: Actual velocity     | The motor speed received from the drive unit at switching is used.*1                                                                                         |
| 2: Automatic selection | The lower velocity between "0: Command velocity" and "1: Actual velocity" is used as the velocity commanded to the drive unit immediately after switching.*2 |

\*1 When object data "Velocity actual value (606CH)" is not mapped, the motor speed received from the drive unit at switching is not used. (Speed initial value selection becomes "0".)

\*2 When object data "Velocity actual value (606CH)" is not mapped, the velocity commanded to the drive unit immediately after switching becomes "0: Command velocity".

## ■Related object data

The following table lists the functions that cause errors or specification restrictions when no object data is set, no PDO is mapped, or when there is no object in the device station.

For details on object data settings, refer to the following.

📖 User's manual for the controller used

◎: Required, ○: Recommended

| Instruction/function            | Required object data  | PDO mapping | Operation when the object is not set                                                                                  |
|---------------------------------|-----------------------|-------------|-----------------------------------------------------------------------------------------------------------------------|
| MC_MoveVelocity (Speed Control) | Target velocity       | ◎           | Necessary Object Data Unset (error code: 1AF7H) occurs.                                                               |
|                                 | Velocity actual value | ○           | Operation set in Velocity initial value selection (Options (Options) bit: 16 and 17)<br>📖 Page 1706 Options (Options) |

## Precautions

- Velocity Override Factor (AxisName.Cd.VelocityOverride) and Acceleration Override Factor (AxisName.Cd.AccelerationOverride) are valid.
  - The set position and the feed machine position are updated by follow up.
  - The switching time of the control mode depends on the specifications of the drive unit.
  - When the stop cause occurs during the control mode switching, the axis will stop immediately.
  - Do not start a positioning control FB while switching the control mode. Check that Driver control mode (AxisName.Md.Driver\_Mode) has switched to "9: Velocity control (csv)" before starting a positioning control FB.
  - When the control mode is switched from cyclic synchronous position mode (csp) to cyclic synchronous velocity mode (csv), follow-up may be performed in cyclic synchronous position mode (csp) until the axis reaches a zero velocity state, if a stop factor (axis error detection) occurs before the control mode is switched.
  - Note the following precautions when using MR-J5(W)-G and switching from csp to csv without waiting for the motor to stop, or when switching from csv to csp.
    - Set servo parameter (extension setting) "ZSP disabled selection at control switching (PC76.1)" to "1: Disabled (control switching is performed regardless of the range of ZSP)" and disable monitoring of zero speed status. Note that doing so may cause vibration or impact to occur at control mode switching.
    - For the setting values of servo parameters (basic setting) "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)", refer to the following.
-  User's manual for the controller used

## Processing details

The following is a program example. The speed control command (bMoveVelocity) is set to TRUE, the mode is switched to velocity mode, and speed control is performed for Axis 1 (Axis0001).

- Setting

| Item         | Setting value |
|--------------|---------------|
| Velocity     | 100000.0      |
| Acceleration | 50000.0       |
| Deceleration | 50000.0       |
| Jerk         | 0.0           |

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

# 46.8 Torque Control

## MC\_TorqueControl

This FB switches the drive unit to cst and performs torque control according to the specified target torque.

| Ladder | FBD/LD | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MC_TorqueControl (Torque Control) is executed.                                                                                                                                                                                |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MC_TorqueControl (Torque Control) is controlling the axis.                                                                                                                                                                   |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MC_TorqueControl (Torque Control) is aborted.<br>The variable becomes FALSE when Execution command (Execute) becomes FALSE.                                                                                      |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                              |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used                                                                                                   |

## Processing details

MC\_TorqueControl (Torque Control) switches the drive unit control mode to cst (cyclic synchronous torque mode) and performs control. This function controls the command torque based on the specified Torque positive direction ramp (TorquePositiveRamp) and Torque negative direction ramp (TorqueNegativeRamp). To finish MC\_TorqueControl (Torque Control), start MC\_Stop (Forced Stop).

## ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Torque positive direction ramp (TorquePositiveRamp)/Torque negative direction ramp(TorqueNegativeRamp)

Set the command torque to be specified.

Set the setting value used from the current command torque until the target torque is reached.

The setting value used until the target torque is reached differs depending on the setting of Torque ramp function selection (Options (Options): Bit 16, 17).

| Torque ramp function selection<br>(Options (Options): Bit 16, 17) | Description                                                                                                                                                                                           | Setting range       |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| 0: Ramp method                                                    | <p>Set the ramp from the current command torque until the target torque is reached.</p>                             | 0.0 to 1000.0 [%/s] |
| 1: Time constant method                                           | <p>Set the time from "0" until the command torque reaches either the positive or negative torque limit value.</p>  | 0.0 to 8400.0 [s]   |
| 2: Fixed time method                                              | <p>Set the time from the current command torque until the target torque is reached.</p>                           | 0.0 to 8400.0 [s]   |

When the output torque direction is changed due to the target torque change, the command torque becomes "0.0" based on the setting value of Torque negative direction ramp (TorqueNegativeRamp). After that, the command torque becomes the target torque based on the setting value of Torque positive direction ramp (TorquePositiveRamp).

When Torque positive direction ramp (TorquePositiveRamp) and Torque negative direction ramp (TorqueNegativeRamp) are set to "0.0", the value reaches the target torque in one operation cycle.

## ■Acceleration (Acceleration)

Sets the acceleration used in MC\_TorqueControl (Torque Control).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 2) | Setting range                                                                          |
|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method<br>(mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MC\_TorqueControl (Torque Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 2) | Setting range                                                                          |
|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method<br>(mcFixedTime)             | Not used                                                                               |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MC\_TorqueControl (Torque Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 2) | Setting range                                                           |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method<br>(mcFixedTime)             | Not used                                                                |

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MC\_TorqueControl (TorqueControl).

| Setting value            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately.<br>Switches to torque control immediately.                                                                                                                                                                                                                                                                                                                                                        |
| 1: Buffered (mcBuffered) | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.<br>Switches to torque control after the processing of the previous FB is completed.<br>When the previous FB is MC_TorqueControl (Torque Control), switches to torque control when Target torque reached (InTorque) is TRUE. |

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

## ■Options (Options)

The function options for MC\_TorqueControl (Torque Control) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*<sup>1</sup> Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/<br>deceleration method<br>setting                                                                  | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"> <li>0: Acceleration/deceleration specification method (mcAccDec)</li> <li>1: Acceleration/deceleration time-fixed method (mcFixedTime)</li> </ul>                                                                                                                               |

| 18     | Torque initial value<br>selection                                                                                | Sets the torque initial value when switching to cyclic synchronous torque mode (cst). <ul style="list-style-type: none"> <li>0: Target torque</li> <li>1: Actual torque</li> </ul>                                                                                                                                                                                                    |
| 19     | Control mode switching<br>selection* <sup>2</sup>                                                                | Sets the switching control mode. <ul style="list-style-type: none"> <li>0: cst (cyclic synchronous torque mode)</li> <li>1: ct (continuous operation to torque control mode)</li> </ul>                                                                                                                                                                                               |
| 20, 21 | Velocity initial value<br>selection at continuous<br>operation to torque<br>control mode switching* <sup>3</sup> | Sets the velocity initial value when changing the control mode from cyclic synchronous position mode (csp) to continuous operation to torque control mode (ct). <ul style="list-style-type: none"> <li>0: Command velocity</li> <li>1: Actual velocity</li> <li>2: Automatic selection</li> </ul>                                                                                     |

\*<sup>2</sup> Switching to continuous operation to torque mode is possible when "Supported drive modes (Obj. 6502Hh) (Bit 20)" of the object data is TRUE. When this bit is set to "1: ct (Continuous operation to torque control mode)" while "Supported drive modes (6502Hh) (Bit 20)" is FALSE, Driver Control Mode Unsupported (error code: 1B1BH) occurs.

For details on continuous operation to torque control mode, refer to the following.

User's manual for the controller used

\*<sup>3</sup> Enabled only when Control mode switching selection (Options (Options): Bit 19) is set to "1: ct (Continuous operation to torque control mode)".

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                   | Description                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration<br>specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MC_TorqueControl (Torque Control)                                                                                                                          |
| 1: Acceleration/deceleration time-fixed<br>method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MC_TorqueControl (Torque Control) regardless of the velocity.<br>The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

• Torque initial value selection (Bit 18)

| Setting value    | Description                                                                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Target torque | Target torque (Torque) value at start is set as the command torque immediately after switching the control mode, regardless of the value in Torque positive direction ramp (TorquePositiveRamp) or Torque negative direction ramp (TorqueNegativeRamp). |
| 1: Actual torque | The value of Torque actual value at switching is set as the command torque.*1                                                                                                                                                                           |

\*1 When an object assigned to object data "Torque actual value" is not mapped to PDO, the actual torque received from the drive unit at switching is not used. "0" is used as the torque initial value.

**Point**

Normally, set this bit to "0: Target torque". Set "1: Actual torque" only when switching the control mode immediately after the command to the motor is completed without waiting for the servo motor to stop.

• Velocity initial value selection at continuous operation to torque control mode switching (Bit 20, 21)

| Setting value          | Description                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Command velocity    | The velocity during command is used as the velocity commanded to the drive unit immediately after switching.                                                 |
| 1: Actual velocity     | The motor speed received from the drive unit at switching is used.*1                                                                                         |
| 2: Automatic selection | The lower velocity between "0: Command velocity" and "1: Actual velocity" is used as the velocity commanded to the drive unit immediately after switching.*2 |

\*1 When object data "Velocity actual value (606CH)" is not mapped, the motor speed received from the drive unit at switching is not used. (Speed initial value selection becomes "0".)

\*2 When object data "Velocity actual value (606CH)" is not mapped, the velocity commanded to the drive unit immediately after switching becomes "0: Command velocity".

## ■Related object data

The following table lists the functions that cause errors or specification restrictions when no object data is set, no PDO is mapped, or when there is no object in the device station.

For details on object data settings, refer to the following.

User's manual for the controller used

◎: Required, ○: Recommended

| Instruction/function                                                 | Required object data  | PDO mapping | Operation when the object is not set                                                                                |

\*1 The item can be set in Control mode switching selection (Options bit 19)

## Precautions

- Velocity Override Factor (AxisName.Cd.VelocityOverride) and Acceleration Override Factor (AxisName.Cd.AccelerationOverride) are valid.
- The set position and the feed machine position are updated by follow up.
- The switching time of the control mode depends on the specifications of the drive unit.
- When the stop cause occurs during the control mode switching, the axis will stop immediately.
- Do not start a positioning control FB while switching the control mode. Check that Driver control mode (AxisName.Md.Driver\_Mode) has switched to "10: Torque control (cst)" before starting the positioning control FB.
- When the control mode is switched from cyclic synchronous position mode (csp) to cyclic synchronous velocity mode (csv), follow-up may be performed in cyclic synchronous position mode (csp) until the axis reaches a zero velocity state, if a stop factor (axis error detection) occurs before the control mode is switched.
- Note the following precautions when using MR-J5(W)-G and switching from csp to cst without waiting for the motor to stop, or when switching from cst to csp.
  - Set servo parameter (extension setting) "ZSP disabled selection at control switching (PC76.1)" to "1: Disabled (control switching is performed regardless of the range of ZSP)" and disable monitoring of zero speed status. Note that doing so may cause vibration or impact to occur at control mode switching.
  - For the setting values of servo parameters (basic setting) "Electronic gear numerator (PA06)" and "Electronic gear denominator (PA07)", refer to the following.
-  User's manual for the controller used
- When Velocity limit value is not mapped, the command torque is changed to 0 when a stop cause occurs.

### ■Torque limit change during cyclic synchronous torque mode (cst)

- At restart or continuous update, if the target torque is changed to a value greater than the torque limit value (Positive direction torque limit value (AxisName.Md.TorqueLimit\_Positive), Negative direction torque limit value (AxisName.Md.TorqueLimit\_Negative)), Torque Limit Value Over Warning (event code: 00D12H) occurs and the axis operates at the value before change.
- During torque control, if Positive direction torque limit value (AxisName.Cd.TorqueLimit\_Positive), Negative direction torque limit value (AxisName.Cd.TorqueLimit\_Negative) are changed to a value smaller than the target torque, the target torque will be changed to the torque limit value. In this case, the command torque is changed in one cycle.

## Program example

The following is a program example. The torque control command (bTorqueControl) is set to TRUE, the mode is switched to torque mode, and torque control is performed for Axis 1 (Axis0001).

- Settings

| Item         | Setting value |
|--------------|---------------|
| Velocity     | 100000.0      |
| Acceleration | 50000.0       |
| Deceleration | 50000.0       |
| Jerk         | 0.0           |

# 46.9 Speed Control (Including Position Loop)

46

## MCv\_SpeedControl

This FB performs speed control including the position loop.

| Ladder | FBD/LD | ST                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Error           | Error                         | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                                                   |
| ErrorID         | Error code                    | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used                                    |

## Processing details

This FB sets the drive unit control mode to csp (cyclic synchronous position mode) and executes the speed control for the specified axis using the specified velocity. To stop the axis, use MC\_Stop (Forced Stop) or start another motion FB. To perform the speed control with the control mode of the drive unit set to csv (cyclic synchronous velocity mode), use MC\_MoveVelocity (Speed Control).

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

☞ Page 1432 Basic operation of Execution command (Execute) type motion control FBs

### ■Velocity (Velocity)

Sets the command velocity used in MCv\_SpeedControl (Speed Control (Including Position Loop)).

#### Setting range

0.0,  $\pm 0.0001$  to  $\pm 25000000000.0^{*1*2}$

- \*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions. If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit ([AxisName.Pr.Unit\\_Position](#)) and Speed command unit ([AxisName.Pr.Unit\\_Velocity](#)) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".
- \*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.

### ■Acceleration (Acceleration)

Sets the acceleration used in MCv\_SpeedControl (Speed Control (Including Position Loop)).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                   |
|--------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | $0.0000^{*1}$ , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | $0.000000^{*1}$ , positive numbers from 0.000001 to 8400.0[s]                   |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 ([AxisName.Pr.AccelerationZeroBehavior](#)). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MCv\_SpeedControl (Speed Control (Including Position Loop)).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

<sup>\*1</sup> The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MCv\_SpeedControl (Speed Control (Including Position Loop)).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>3</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MCv\_SpeedControl (Speed Control (Including Position Loop)).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                                          |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                                    |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB. <sup>*1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB. <sup>*1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB. <sup>*1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB. <sup>*1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

<sup>\*1</sup> Stops are not performed between the under-control FB and the buffering FB.

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

## ■Options (Options)

The function options for MCv\_SpeedControl (Speed Control (Including Position Loop)) are set in the specified bit position. The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                            | Description                                                                                                                                                                                                                                             |
|--------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/<br>deceleration method<br>setting | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"> <li>0: Acceleration/deceleration specification method (mcAccDec)</li> <li>1: Acceleration/deceleration time-fixed method (mcFixedTime)</li> </ul> |

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                   | Description                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration<br>specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MCv_SpeedControl (Speed Control (Including Position Loop)).                                                                                                                         |
| 1: Acceleration/deceleration time-fixed<br>method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MCv_SpeedControl (Speed Control (Including Position Loop)) regardless of the velocity.<br>The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

## ■ Operation overview

- The operation at start and when a stop cause occurs is shown below.

- If the sign of Velocity (Velocity) is reversed and the operation direction is changed when Continuous update (ContinuousUpdate) is TRUE, the axis accelerates toward the target velocity once after the deceleration stop.

## ■ Necessary object data

When using MCv\_SpeedControl (Speed Control (Including Position Loop)) for a single axis, set the following object data for the axis.

- Target position (607AH)

If the object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

📖 User's manual for the controller used

## Program example

The following is a program example. The speed control command (bSpeedControl) is set to TRUE, the mode is switched to speed control including position loop, and speed control including position loop is performed for Axis 1 (Axis0001).

- Setting

| Item         | Setting value |
|--------------|---------------|
| Velocity     | 100000.0      |
| Acceleration | 50000.0       |
| Deceleration | 50000.0       |
| Jerk         | 0.0           |

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |

### ■Labels used

| Label name         | Data type                           | Comment                 |
|--------------------|-------------------------------------|-------------------------|
| MCv_SpeedControl_1 | MCv_SpeedControl                    | Speed Control FB        |
| bSpeedControl      | Bit                                 | Speed control command   |
| leVelocity         | Double-precision real number        | Command velocity        |
| leAcceleration     | Double-precision real number        | Acceleration            |
| leDeceleration     | Double-precision real number        | Deceleration            |
| leJerk             | Double-precision real number        | Jerk                    |
| bInVelocity        | Bit                                 | Target velocity reached |
| bBusy              | Bit                                 | Executing               |
| bActive            | Bit                                 | Controlling             |
| bCommandAborted    | Bit                                 | Abortion of execution   |
| bError             | Bit                                 | Error                   |
| uwErrorID          | Word [unsigned]/bit string [16-bit] | Error code              |

# 46.10 Absolute Value Linear Interpolation Control

## MCv\_MoveLinearInterpolateAbsolute

This FB specifies the target position of the absolute position of the set axes group and performs positioning by linear interpolation control.

| Ladder | FBD/LD | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
