| Done            | Completion            | BOOL       | FALSE         | This variable becomes TRUE when the control is completed.<br>The value differs depending on the status of Start (Execute) at operation completion.<br>■When Start (Execute) is TRUE<br>This variable remains TRUE until Start (Execute) is set to FALSE.<br>■When Start (Execute) is FALSE<br>This variable becomes TRUE only for one cycle.                                                                           |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) is executed.                                                                                                                                                                                                                                                                                           |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) is controlling the axis.<br>When multiple MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) FBs are executed for the same axes group, Controlling (Active) of only one MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) FB becomes TRUE. |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution of MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) is aborted because of an error or multiple start.                                                                                                                                                                                                                                         |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                                                                                                                                                                                       |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used                                                                                                                                                                        |

## Processing details

- This FB specifies an axes group and performs interpolation control so that the path from the start point (move start point) to the end point becomes a straight line. In linear interpolation control, interpolation control using a maximum of 4 axes is performed.
- In MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control), specify the target position used for the absolute position and perform absolute value linear interpolation control.
- For the operation of Absolute Value Linear Interpolation Control for axes 1 to 3, refer to "Linear Interpolation Control" in the following.

 User's manual for the controller used

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

### ■Linear interpolation axis (LinearAxes)

In linear interpolation control, linear interpolation is performed using arbitrary axes from the configuration axes set to the axes group.

Set configuration axes to perform linear interpolation by Linear interpolation axis (LinearAxes) from the configuration axes of the axes group. Linear interpolation axis (LinearAxes) has 16 array elements. For the arrays, first set only the index Nos. (1 to 16: configuration axis 1 to 16) of configuration axes to be used for interpolation control to the front, then set the rest of the arrays to "0". Arrays set to "0" can be omitted.

- The setting number of the linear interpolation axes must be set to the maximum number of the interpolation axes for interpolation control (4 axes) or less.
- The number of configuration axes to be used for interpolation control must be the number of axes registered to the configuration axes or less.
- When Velocity mode (VelocityMode) is "2: Reference axis speed (ReferenceAxisSpeed)", the configuration axis of the first element in Linear interpolation axis (LinearAxes) becomes the reference axis.
- If the following is specified, Linear Interpolation Axis Setting Incorrect (error code: 1B08H) occurs and the axis will not start.
  - When specifying a configuration axis where an axis is not set
  - When the first element of Linear interpolation axis (LinearAxes) is "0"
  - When specifying the same index No. to Linear interpolation axis (LinearAxes) in duplicate
  - When the number of axes set in Linear interpolation axis (LinearAxes) exceeds the maximum number of interpolation axes

**Ex.**

When configuration axis 2, 3, and 4 are set to the linear interpolation axis

```
LinearAxes[0]:= 2;
LinearAxes[1]:= 3;
LinearAxes[2]:= 4;
LinearAxes[3]:= 0; *1
:
LinearAxes[15]:= 0; *1
```

\*1 "LinearAxes[3]:= 0; to LinearAxes[15]:= 0;" can be omitted.

**■Target position (Position)**

Sets the target position for linear interpolation.

Target position (Position) has 16 array elements.

- The valid range differs depending on whether the software stroke limit is valid/invalid, Direction selection (Direction), and the setting for Target position specification exceeding the ring counter (Options (Options): Bit 16). For details, refer to the following.

 Page 1672 Target position (Position)

- Position[0..15] indicates the target position of configuration axis 1 to 16. Set the position in relation to the configuration axes set in Linear interpolation axis (LinearAxes).
- Target position (Position) of configuration axes not set to the linear interpolation axes is ignored.
- Target position (Position) of axes after all configuration axes set to the linear interpolation axes can be omitted.

**Ex.**

When setting configuration axis 2, 3, 4 to the linear interpolation axes, and setting the target positions of configuration axis 2, 3, and 4 to 2000.0, 3000.0, and 4000.0

```
LinearAxes[0]:= 2;
LinearAxes[1]:= 3;
LinearAxes[2]:= 4;
LinearAxes[3]:= 0; *1
:
LinearAxes[15]:= 0; *1
Position[0]:= 0.0;
Position[1]:= 2000.0;
Position[2]:= 3000.0;
Position[3]:= 4000.0;
Position[4]:= 0.0; *1
:
Position[15]:= 0.0; *1
```

\*1 "LinearAxes[3]:= 0; to LinearAxes[15]:= 0;" and "Position[4]:= 0.0; to Position[15]:= 0.0;" can be omitted.

**■Velocity (Velocity)**

Sets the maximum speed of the path used in MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control).

**Setting range**

0.0, 0.0001 to 25000000000.0 \*1\*2

- \*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.  
If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (AxisName.Pr.Unit\_Position) and Speed command unit (AxisName.Pr.Unit\_Velocity) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".
- \*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.

### ■Acceleration (Acceleration)

Sets the acceleration used in MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

### ■Deceleration (Deceleration)

Sets the deceleration used in MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

### ■Jerk (Jerk)

Sets the jerk used in MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Velocity mode (VelocityMode)

Specifies the velocity mode used in linear interpolation control. When specifying "2: Reference axis speed (ReferenceAxisSpeed)" in Velocity mode (VelocityMode), the reference axis becomes the configuration axis specified to the first element of Linear interpolation axis (LinearAxes).

| Setting value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 2: Reference axis speed<br>(ReferenceAxisSpeed) | <p>Sets Velocity (Velocity) as the velocity of the reference axis.</p> <p>The Motion system calculates the positioning speed (Vn) of the other interpolation axes from the movement amount (Dn) of each interpolation axis and performs control based on the positioning speed of the set reference axis (the reference axis velocity: V).</p> <p>If "0.0" is set for the movement amount of the configuration axis specified as the reference axis, Reference Axis Movement Amount 0 (error code: 1AFAH) occurs.</p> <p>&lt;Example&gt;</p> <p>When using 4-axis linear interpolation control</p> <ul style="list-style-type: none"> <li>• Configuration axis 1 movement amount (D<sub>1</sub>): 10000.0 [pulse]</li> <li>• Configuration axis 2 movement amount (D<sub>2</sub>): 15000.0 [pulse]</li> <li>• Configuration axis 3 movement amount (D<sub>3</sub>): 5000.0 [pulse]</li> <li>• Configuration axis 4 movement amount (D<sub>4</sub>): 20000.0 [pulse]</li> <li>• Reference axis velocity (V): 7000.0 [pulse/s]</li> </ul> <p>In the above case, the long axis is configuration axis 4 whose movement amount is the largest, and the control is carried out based on the positioning speed set for configuration axis 4.</p> <p>The positioning speed of the other configuration axes is calculated by the Motion system with the following calculation formulas.</p> <ul style="list-style-type: none"> <li>• Configuration axis 1 positioning speed: <math>V_1 = D_1 / D_4 \times V</math></li> <li>• Configuration axis 2 positioning speed: <math>V_2 = D_2 / D_4 \times V</math></li> <li>• Configuration axis 3 positioning speed: <math>V_3 = D_3 / D_4 \times V</math></li> </ul> <p>■Point</p> <ul style="list-style-type: none"> <li>• For the reference axis speed specification, the set speed limit value is valid as the reference axis velocity for Velocity (Velocity).</li> <li>• Note that the positioning speed may be larger than the set reference axis velocity for axes with a movement amount larger than the reference axis. When a value is set as shown below in the 2-axis linear interpolation, the positioning speed and the vector velocity of configuration axis 2 exceed the velocity limit value.</li> </ul> <p>&lt;Example&gt;</p> <p>When the setting items and the setting values are as follows.</p> <ul style="list-style-type: none"> <li>• Linear interpolation axes: Configuration axis 1, Configuration axis 2</li> <li>• Configuration axis 1 movement amount: 100 [pulses]</li> <li>• Configuration axis 2 movement amount: 200 [pulses]</li> <li>• Reference axis velocity: 50 [pulses/s]</li> <li>• Velocity limit value of configuration axis 1: 55 [pulses/s]</li> </ul> <p>In the above case, the reference axis is configuration axis 1, and control is carried out with the velocity limit value set for configuration axis 1. The positioning speed and the vector velocity of each axis are shown below.</p> <ul style="list-style-type: none"> <li>• Configuration axis 1 positioning speed: 50 [pulses/s]</li> <li>• Configuration axis 2 positioning speed: <math>200/100 \times 50 = 100</math> [pulses/s]</li> <li>• Vector velocity: <math>\sqrt{(50^2 + 100^2)} = 111.8</math> [pulses/s]</li> </ul> <p>The positioning speed and the vector velocity of configuration axis 2 become a value that exceeds the velocity limit value "55" of configuration axis 1.</p> |

### Restriction

- When "0: Vector speed (VectorSpeed)" is set in Velocity mode (VelocityMode) and the movement value of each axis exceeds "4,294,967,296.0 (=2<sup>32</sup>)", Out of Linear Movement Amount Range (error code: 1B10H) will occur and the axis will not start.
- When "0: Aborting (mcAborting)" is set in Buffer mode (BufferMode) and MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) is executed by multiple start, specify "0: Vector speed (VectorSpeed)" in Velocity mode (VelocityMode). If a value other than "0: Vector speed (VectorSpeed)" is set, Out of Speed Mode Range (error code: 1AC9H) occurs.

## ■Direction selection (Direction)

Specifies the direction used to move from the current position to the target position by selecting positive direction, negative direction, or shortest way. Direction selection (Direction) has 16 array elements.

- Direction[0..15] indicates the direction selection of configuration axis 1 to 16. Set the value for the configuration axis set in Linear interpolation axis (LinearAxes).
- The direction selection (Direction) of the configuration axis which is not set as the linear interpolation axis is ignored.
- Direction selection (Direction) of axes after all configuration axes set to the linear interpolation axes can be omitted.
- If a setting value is not set, Out of Direction Selection Range (error code: 1AA5H) occurs and the axis will not start.
- A linear axis where the software stroke limit is valid ignores the setting of Direction selection (Direction). For details on operation of each direction selection, refer to the following.

 Page 1674 Direction selection (Direction)

| Setting value                               | Description                                                                                                           |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| 1: Positive direction (mcPositiveDirection) | Performs positioning in the positive direction (address increasing) from the current position to the target position. |
| 2: Negative direction (mcNegativeDirection) | Performs positioning in the negative direction (address decreasing) from the current position to the target position. |
| 3: Shortest path (mcShortestWay)            | Based on the current position, positioning control is performed in the direction closest to the target position.      |

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                              |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                        |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*1 Stops are not performed between the under-control FB and the buffering FB.

For details on multiple start (buffer mode), refer to the following.

 User's manual for the controller used

## Options (Options)

The function options for MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                                           | Description                                                                                                                                                                                            |
|--------|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration<br>specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control).                                                                                                                      |
| 1: Acceleration/deceleration time-fixed<br>method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MCv_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) regardless of the velocity. The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

## Necessary object data

When using MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control), set the following object data for all configuration axes in the specified axes group.

- Target position (607AH)

If there is a structuring axis for which no object data is set, Necessary Object Data Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

User's manual for the controller used

## Program example

The following is a program example. The linear interpolation control start (bLinearInterpolateCMD) is set to TRUE, and Axes group 1 (AxesGroup001) is enabled. Then, 2-axis linear interpolation absolute positioning control is performed for Axis group 1 (AxesGroup001).

### • Operation

### • Axes group

| Item                  | Setting value |
|-----------------------|---------------|
| Configuration axis[1] | Axis0001      |
| Configuration axis[2] | Axis0002      |

### • Setting

| Item                | Setting value        |                      |
|---------------------|----------------------|----------------------|
|                     | Configuration axis 1 | Configuration axis 2 |
| Target position     | 50000.0              | 40000.0              |
| Velocity            | 50000.0              |                      |
| Acceleration        | 50000.0              |                      |
| Deceleration        | 50000.0              |                      |
| Jerk                | 0.0                  |                      |
| Direction selection | Positive direction   | Positive direction   |

## ■Axes

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |
| 2        | Axis0002   | AXIS_REF  | Axis 2  |

## ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

# 46.11 Relative Value Linear Interpolation Control

46

## MCv\_MoveLinearInterpolateRelative

This FB specifies the movement amount of the relative position of the set axes group and performs positioning by linear interpolation control.

| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br>User's manual for the controller used                                                                                                                                                                                                                                                         |

## Processing details

- This FB specifies an axes group and performs interpolation control so that the path from the start point (move start point) to the end point becomes a straight line. In linear interpolation control, interpolation control using a maximum of 4 axes is performed.
- In MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control), specify the relative movement amount from the current position and perform relative value linear interpolation control.
- For the operation of Relative Value Linear Interpolation Control for axes 1 to 3, refer to "Linear Interpolation Control" in the following.

User's manual for the controller used

## Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ Linear interpolation axis (LinearAxes)

In linear interpolation control, linear interpolation is performed using arbitrary axes from the configuration axes set to the axes group.

Set configuration axes to perform linear interpolation by Linear interpolation axis (LinearAxes) from the configuration axes of the axes group. Linear interpolation axis (LinearAxes) has 16 array elements. For the arrays, first set only the index Nos. (1 to 16: configuration axis 1 to 16) of configuration axes to be used for interpolation control to the front, then set the rest of the arrays to "0". Arrays set to "0" can be omitted.

- The setting number of the linear interpolation axes must be set to the maximum number of the interpolation axes for interpolation control (4 axes) or less.
- The number of configuration axes to be used for interpolation control must be the number of axes registered to the configuration axes or less.
- When Velocity mode (VelocityMode) is "2: Reference axis speed (ReferenceAxisSpeed)", the configuration axis of the first element in Linear interpolation axis (LinearAxes) becomes the reference axis.
- If the following is specified, Linear Interpolation Axis Setting Incorrect (error code: 1B08H) occurs and the axis will not start.
  - When specifying a configuration axis where an axis is not set
  - When the first element of Linear interpolation axis (LinearAxes) is "0"
  - When specifying the same index No. to Linear interpolation axis (LinearAxes) in duplicate
  - When the number of axes set in Linear interpolation axis (LinearAxes) exceeds the maximum number of interpolation axes

### Ex.

When configuration axis 2, 3, and 4 are set to the linear interpolation axis

```
LinearAxes[0]:= 2;  
LinearAxes[1]:= 3;  
LinearAxes[2]:= 4;  
LinearAxes[3]:= 0; *1  
:  
LinearAxes[15]:= 0; *1
```

\*1 "LinearAxes[3]:= 0; to LinearAxes[15]:= 0;" can be omitted.

## ■ Movement amount (Distance)

Sets the movement amount from the current position at start to the end point. Movement amount (Distance) has 16 array elements.

- The input range for Movement amount (Distance) is -10000000000.0 to 10000000000.0.
- Distance[0..15] indicates the movement amount of configuration axis 1 to 16. Set the position in relation to the configuration axes set in Linear interpolation axis (LinearAxes).
- Movement amount (Distance) of configuration axes not set to the linear interpolation axes is ignored.
- Movement amount (Distance) of axes after all configuration axes set to the linear interpolation axes can be omitted.

### Ex.

When setting configuration axis 2, 3, 4 to the linear interpolation axes, and setting the target positions of configuration axis 2, 3, and 4 to 2000.0, 3000.0, and 4000.0

```
LinearAxes[0]:= 2;
LinearAxes[1]:= 3;
LinearAxes[2]:= 4;
LinearAxes[3]:= 0; *1
:
LinearAxes[15]:= 0; *1
Distance[0]:= 0.0;
Distance[1]:= 2000.0;
Distance[2]:= 3000.0;
Distance[3]:= 4000.0;
Distance[4]:= 0.0; *1
:
Distance[15]:= 0.0; *1
```

\*1 "LinearAxes[3]:= 0; to LinearAxes[15]:= 0;" and "Distance[4]:= 0.0; to Distance[15]:= 0.0;" can be omitted.

## ■Velocity (Velocity)

Sets the maximum speed of the path used in MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control).

| Setting range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0.0, 0.0001 to 2500000000.0 <sup>*1,2</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p>*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.<br/>If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (<u>AxisName</u>.Pr.Unit_Position) and Speed command unit (<u>AxisName</u>.Pr.Unit_Velocity) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".</p> <p>*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.</p> |

## ■Acceleration (Acceleration)

Sets the acceleration used in MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>3</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Velocity mode (VelocityMode)

Specifies the velocity mode used in linear interpolation control. When specifying "2: Reference axis speed (ReferenceAxisSpeed)" in Velocity mode (VelocityMode), the reference axis becomes the configuration axis specified to the first element of Linear interpolation axis (LinearAxes).

| Setting value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 2: Reference axis speed<br>(ReferenceAxisSpeed) | <p>Sets Velocity (Velocity) as the velocity of the reference axis.</p> <p>The Motion system calculates the positioning speed (Vn) of the other interpolation axes from the movement amount (Dn) of each interpolation axis and performs control based on the positioning speed of the set reference axis (the reference axis velocity: V).</p> <p>If "0.0" is set for the movement amount of the configuration axis specified as the reference axis, Reference Axis Movement Amount 0 (error code: 1AFAH) occurs.</p> <p>&lt;Example&gt;</p> <p>When using 4-axis linear interpolation control</p> <ul style="list-style-type: none"> <li>• Configuration axis 1 movement amount (D<sub>1</sub>): 10000.0 [pulse]</li> <li>• Configuration axis 2 movement amount (D<sub>2</sub>): 15000.0 [pulse]</li> <li>• Configuration axis 3 movement amount (D<sub>3</sub>): 5000.0 [pulse]</li> <li>• Configuration axis 4 movement amount (D<sub>4</sub>): 20000.0 [pulse]</li> <li>• Reference axis velocity (V): 7000.0 [pulse/s]</li> </ul> <p>In the above case, the long axis is configuration axis 4 whose movement amount is the largest, and the control is carried out based on the positioning speed set for configuration axis 4.</p> <p>The positioning speed of the other configuration axes is calculated by the Motion system with the following calculation formulas.</p> <ul style="list-style-type: none"> <li>• Configuration axis 1 positioning speed: <math>V_1 = D_1 / D_4 \times V</math></li> <li>• Configuration axis 2 positioning speed: <math>V_2 = D_2 / D_4 \times V</math></li> <li>• Configuration axis 3 positioning speed: <math>V_3 = D_3 / D_4 \times V</math></li> </ul> <p>■Point</p> <ul style="list-style-type: none"> <li>• For the reference axis speed specification, the set speed limit value is valid as the reference axis velocity for Velocity (Velocity).</li> <li>• Note that the positioning speed may be larger than the set reference axis velocity for axes with a movement amount larger than the reference axis. When a value is set as shown below in the 2-axis linear interpolation, the positioning speed and the vector velocity of configuration axis 2 exceed the velocity limit value.</li> </ul> <p>&lt;Example&gt;</p> <p>When the setting items and the setting values are as follows.</p> <ul style="list-style-type: none"> <li>• Linear interpolation axes: Configuration axis 1, Configuration axis 2</li> <li>• Configuration axis 1 movement amount: 100 [pulses]</li> <li>• Configuration axis 2 movement amount: 200 [pulses]</li> <li>• Reference axis velocity: 50 [pulses/s]</li> <li>• Velocity limit value of configuration axis 1: 55 [pulses/s]</li> </ul> <p>In the above case, the reference axis is configuration axis 1, and control is carried out with the velocity limit value set for configuration axis 1. The positioning speed and the vector velocity of each axis are shown below.</p> <ul style="list-style-type: none"> <li>• Configuration axis 1 positioning speed: 50 [pulses/s]</li> <li>• Configuration axis 2 positioning speed: <math>200/100 \times 50 = 100</math> [pulses/s]</li> <li>• Vector velocity: <math>\sqrt{(50^2 + 100^2)} = 111.8</math> [pulses/s]</li> </ul> <p>The positioning speed and the vector velocity of configuration axis 2 become a value that exceeds the velocity limit value "55" of configuration axis 1.</p> |

### Restriction

- When "0: Vector speed (VectorSpeed)" is set in Velocity mode (VelocityMode) and the movement value of each axis exceeds "4,294,967,296.0 (=2<sup>32</sup>)", Out of Linear Movement Amount Range (error code: 1B10H) will occur and the axis will not start.
- When "0: Aborting (mcAborting)" is set in Buffer mode (BufferMode) and MCv\_MoveLinearInterpolateAbsolute (Absolute Value Linear Interpolation Control) is executed by multiple start, specify "0: Vector speed (VectorSpeed)" in Velocity mode (VelocityMode). If a value other than "0: Vector speed (VectorSpeed)" is set, Out of Speed Mode Range (error code: 1AC9H) occurs.

## ■ Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                              |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                        |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.*1<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*1 Stops are not performed between the under-control FB and the buffering FB.

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

## Options (Options)

The function options for MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                            | Description                                                                                                                                                                                                                                                                     |
|--------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/<br>deceleration method<br>setting | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"><li>• 0: Acceleration/deceleration specification method (mcAccDec)</li><li>• 1: Acceleration/deceleration time-fixed method (mcFixedTime)</li></ul>                        |
| 3      | Position selection during<br>buffer mode        | Sets the position when executing relative positioning control by multiple start. <ul style="list-style-type: none"><li>• 0: Set position</li><li>• 1: Actual position</li></ul> <p>* This bit is valid when setting "0: Aborting (mcAborting)" in Buffer mode (BufferMode).</p> |

### • Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                   | Description                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration<br>specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control).                                                                                                                      |
| 1: Acceleration/deceleration time-fixed<br>method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MCv_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control) regardless of the velocity. The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

### • Position selection during buffer mode (Bit 3)

## ■ Necessary object data

When using MCv\_MoveLinearInterpolateRelative (Relative Value Linear Interpolation Control), set the following object data for all configuration axes in the specified axes group.

- Target position (607AH)

If there is a configuration axis where object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

📖 User's manual for the controller used

## Program example

The following is a program example. The linear interpolation control start (bLinearInterpolateCMD) is set to TRUE, and Axes group 1 (AxesGroup001) is enabled. Then, 2-axis linear interpolation relative positioning control is performed for Axis group 1 (AxesGroup001).

- Operation

- Axes group

| Item                  | Setting value |
|-----------------------|---------------|
| Configuration axis[1] | Axis0001      |
| Configuration axis[2] | Axis0002      |

- Setting

| Item            | Setting value        |                      |
|-----------------|----------------------|----------------------|
|                 | Configuration axis 1 | Configuration axis 2 |
| Target position | 50000.0              | 50000.0              |
| Velocity        | 50000.0              |                      |
| Acceleration    | 50000.0              |                      |
| Deceleration    | 50000.0              |                      |
| Jerk            | 0.0                  |                      |

## ■ Axes

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |
| 2        | Axis0002   | AXIS_REF  | Axis 2  |

## ■ Axes group

| Axes group No. | Label name   | Data type      | Comment      |

# 46.12 Absolute Value Circular Interpolation Control

46

## MCv\_MoveCircularInterpolateAbsolute

This FB performs positioning with 2-axis circular interpolation using the configuration axes of the set axes group by setting the end point and sub point of the absolute position.

| Ladder                                                                                                                                                                                                                                                                                                                                                            | FBD/LD                                                                                                                                                                                                                                                             | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Processing details

- This FB specifies an axes group and performs interpolation control mechanically so that the path from the start point (move start point) to the end point forms an arc for a linear axis which is orthogonally arranged.
- In circular interpolation control, interpolation control is performed using two arbitrary axes from the configuration axes set to the axes group.
- For circular interpolation control, the border point specification, center point specification, and radius specification circular interpolation methods are settable.
- In MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control), 2-axis circular interpolation control is performed by specifying the end point or sub point of the absolute position.

## ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

### ■Circular interpolation axis (CircAxes)

In circular interpolation control, circular interpolation is performed by using two arbitrary axes from the configuration axes set to the axes group.

The axes used to perform circular interpolation are specified from the configuration axes in the axes group by using Circular interpolation axis (CircAxes). The Circular interpolation axis (CircAxes) has two array elements. For the arrays, specify the index Nos. (1 to 16: configuration axis 1 to 16) of configuration axes to be used for interpolation control.

The first element of the array is regarded as the reference axis.

If the configuration axis specified does not have an axis set, Circular Interpolation Axis Unset (error code: 1ACAH) occurs.

#### Ex.

When setting configuration axes 2 and 3 as the circular interpolation axes

```
CircAxes[0]:= 2;
```

```
CircAxes[1]:= 3;
```

### ■Circular interpolation mode (CircMode)

Sets the circular interpolation method (border point specification, center point specification, or radius specification) used to perform circular interpolation control.

The contents set in Sub point (AuxPoint) differ depending on the setting of Circular interpolation mode (CircMode).

| Setting value                               | Sub point (AuxPoint)                                                                                                                                                                                                                                                                 |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Border point specification<br>(mcBorder) | Sub point (AuxPoint) sets the border point on the arc connecting the start point and the end point.<br>Positioning control with arc path that passes through the specified border point is performed using the two configuration axes set in Circular interpolation axis (CircAxes). |
| 1: Center point specification<br>(mcCenter) | Sub point (AuxPoint) sets the center point of the arc.<br>Positioning control with an arc path having the center point at its center is performed using the two configuration axes set in Circular interpolation axis (CircAxes).                                                    |
| 2: Radius specification<br>(mcRadius)       | Sub point (AuxPoint) sets the radius of the arc.<br>Positioning control with an arc path having the specified radius is performed using the two configuration axes set in Circular interpolation axis (CircAxes).                                                                    |

For the operation of each circular interpolation control set in Circular interpolation mode (CircMode), refer to the following.

 User's manual for the controller used

## ■Sub point (AuxPoint)

Sets the position of the sub point (border point, center point, or radius) used to perform circular interpolation.

Sub point (AuxPoint) has 16 array elements. The contents set in Sub point (AuxPoint) differ depending on the setting of Circular interpolation mode (CircMode).

| Circular interpolation mode (CircMode)   | Setting range                                            | Sub point (AuxPoint) setting                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Border point specification (mcBorder) | -10000000000.0 ≤ Set value < 10000000000.0 <sup>*1</sup> | Sub point (AuxPoint) sets the border point on the arc connecting the start point and the end point.<br>AuxPoint[0..15] indicates the sub point position of configuration axis 1 to 16.<br><ul style="list-style-type: none"> <li>Sub point (AuxPoint) of configuration axes not set to the circular interpolation axes is ignored.</li> <li>Sub point (AuxPoint) of axes after all configuration axes set to the circular interpolation axes can be omitted.</li> </ul> |
| 1: Center point specification (mcCenter) |                                                          | Sub point (AuxPoint) sets the center point of the arc.<br>AuxPoint[0..15] indicates the sub point position of configuration axis 1 to 16.<br><ul style="list-style-type: none"> <li>Sub point (AuxPoint) of configuration axes not set to the circular interpolation axes is ignored.</li> <li>Sub point (AuxPoint) of axes after all configuration axes set to the circular interpolation axes can be omitted.</li> </ul>                                              |
| 2: Radius specification (mcRadius)       | 0.000001 to 2147483647.0                                 | Sub point (AuxPoint) sets the radius of the arc.<br>AuxPoint[0] indicates the radius of the circle.<br><ul style="list-style-type: none"> <li>Inputs after AuxPoint[1] are ignored and can be omitted.</li> </ul>                                                                                                                                                                                                                                                       |

\*1 When the ring counter is enabled, the ring counter range is used.

### Ex.

When setting configuration axis 2 and 3 to the circular interpolation axes and setting the absolute position of the sub point for configuration axis 2 and 3 as 2000.0 and 3000.0

```
CircAxes[0]:= 2;
CircAxes[1]:= 3;
AuxPoint[0]:= 0.0;
AuxPoint[1]:= 2000.0;
AuxPoint[2]:= 3000.0;
AuxPoint[3]:= 0.0; *2
⋮
AuxPoint[15]:= 0.0; *2
```

\*2 "AuxPoint[3]:= 0.0; to AuxPoint[15]:= 0.0;" can be omitted.

## ■End point (EndPoint)

Sets the end point of the absolute position.

End point (EndPoint) has 16 array elements. EndPoint[0..15] indicates the end point position of configuration axis 1 to 16.

- End point (EndPoint) for configuration axes which are not set to the circular interpolation axis are ignored.
- End point (EndPoint) after all of the configuration axes which are set to the circular interpolation axis can be omitted.

Set End point (EndPoint) within the following range.

| Setting range                                            |
|----------------------------------------------------------|
| -10000000000.0 ≤ Set value < 10000000000.0 <sup>*1</sup> |

\*1 When the ring counter is enabled, the ring counter range is used.

## ■Path selection (PathChoice)

Sets the rotation direction for circular interpolation. For the rotation direction, the first element of the array set in Circular interpolation axis (CircAxes) is regarded as the reference axis.

Path selection (PathChoice) is set when Circular interpolation mode (CircMode) is set to "1: Center point specification (mcCenter)" or "2: Radius specification (mcRadius)". When "0: Border point specification (mcBorder)" is set, this input is omitted.

The following shows the setting value, setting description, arc center angle that can be controlled, and path of Path selection (PathChoice) according to the setting of Circular interpolation mode (CircMode).

- Path for "1: Center point specification (mcCenter)"

| Setting value            | Setting description                                                                                                                                                                                                                                                                                                     | Arc center angle that can be controlled | Path |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|------|
| 0: CW (mcCW)             | CW                                                                                                                                                                                                                                                                                                                      | $0^\circ < \theta \leq 360^\circ$       |      |
| 1: CCW (mcCCW)           | CCW                                                                                                                                                                                                                                                                                                                     | $0^\circ < \theta \leq 360^\circ$       |      |
| 2: Shortcut (mcShortWay) | Shortcut <ul style="list-style-type: none"> <li>• When the start point, center point, and end point are on one straight line, becomes CW. (A semicircle is drawn in the CW direction.)</li> <li>• If the start point is the same as the end point, Path Choice Setting Incorrect (error code: 1B06H) occurs.</li> </ul> | $0^\circ < \theta \leq 180^\circ$       |      |
| 3: Detour (mcLongWay)    | Detour <ul style="list-style-type: none"> <li>• When the start point, center point, and end point are on one straight line, becomes CW. (A semicircle is drawn in the CW direction.)</li> <li>• When the start point is same as the end point, becomes CW. (A perfect circle is drawn in CW direction.)</li> </ul>      | $180^\circ \leq \theta \leq 360^\circ$  |      |

- Path for "2: Radius specification (mcRadius)"

| Setting value                | Setting description                                                                                                                                         | Arc center angle that can be controlled | Path |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|------|
| 0: CW (mcCW)                 | CW (CW shortcut)<br>• If the start point, center point, and end point are on one straight line, Path Choice Setting Incorrect (error code: 1B06H) occurs.   | $0^\circ < \theta < 180^\circ$          |      |
| 1: CCW (mcCCW)               | CCW (CCW shortcut)<br>• If the start point, center point, and end point are on one straight line, Path Choice Setting Incorrect (error code: 1B06H) occurs. | $0^\circ < \theta < 180^\circ$          |      |
| 4: CW Detour (mcCWLongWay)   | CW detour<br>• When the start point, end point, and center point are on one straight line, a semicircle is drawn.                                           | $180^\circ \leq \theta < 360^\circ$     |      |
| 5: CCW Detour (mcCCWLongWay) | CCW detour<br>• When the start point, end point, and center point are on one straight line, a semicircle is drawn.                                          | $180^\circ \leq \theta < 360^\circ$     |      |

## ■Velocity (Velocity)

Sets the maximum speed of the path used in MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control).

| Setting range                               |
|---------------------------------------------|
| 0.0, 0.0001 to 2500000000.0 <sup>*1,2</sup> |

- \*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.  
If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (AxisName.Pr.Unit\_Position) and Speed command unit (AxisName.Pr.Unit\_Velocity) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".
- \*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.

## ■Acceleration (Acceleration)

Sets the acceleration used in MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Circular interpolation error tolerance (CircularErrorTolerance)

In circular interpolation control with center point specification, the arc path calculated from the start position and center position may deviate from the end position set in End point (EndPoint).

Circular interpolation error tolerance (CircularErrorTolerance) sets the allowable width of errors between the calculated arc path and the end position.

| Setting range                                                                      | Description                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Calculated error ≤ Circular interpolation error tolerance (CircularErrorTolerance) | <p>Circular interpolation control to the set end point address is performed while the error compensation is carried out by spiral interpolation.</p>  |
| Calculated error > Circular interpolation error tolerance (CircularErrorTolerance) | <p>At the positioning start, Circular Interpolation Error Allowable Value Over (error code: 1AD9H) occurs and the control will not start. The operation will immediately stop if the error is detected during positioning control.</p>    |

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                                          |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                                    |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. | 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*<sup>1</sup> Stops are not performed between the under-control FB and the buffering FB.

### Point

For details on multiple start (buffer mode), refer to the following.

📖 User's manual for the controller used

## ■Options (Options)

The function options for MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*<sup>1</sup> Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                            | Description                                                                                                                                                                                            |
|--------|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/<br>deceleration method<br>setting | Sets the acceleration/deceleration method used to perform control.<br>• 0: Acceleration/deceleration specification method (mcAccDec)<br>• 1: Acceleration/deceleration time-fixed method (mcFixedTime) |

• Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                | Description                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MCv_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control).                                                                                                                      |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MCv_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control) regardless of the velocity. The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

## ■ Necessary object data

When using MCv\_MoveCircularInterpolateAbsolute (Absolute Value Circular Interpolation Control), set the following object data for all configuration axes in the specified axes group.

- Target position (607AH)

If there is a configuration axis where object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

📖 User's manual for the controller used

## Precautions

- Circular interpolation including an axis whose stroke limit is set to invalid cannot be performed. Software stroke limit invalid at circular interpolation (error code: 1ADAH) occurs and the operation does not start.
- When the interpolation path exceeds the stroke limit range during interpolation operation, Software stroke limit over (forward direction) (error code: 1A83H) or Software stroke limit over (reverse direction) (error code: 1A84H) occurs and the operation will stop.

### Ex.

When the upper limit of the software stroke limit is exceeded in the positive direction of the Y-axis

For an immediate stop, stops at the same time that the error occurs.

For a deceleration stop, decelerates to a stop along the arc of the circle as shown below.

## Program example

The following is a program example. The circular interpolation control start (bCircularInterpolateCMD) is set to TRUE, and Axes group 1 (AxesGroup001) is enabled. Then, 2-axis circular interpolation (sub point specification) absolute positioning control is performed for Axis group 1 (AxesGroup001).

### • Operation

### • Axes group

| Item                  | Setting value |
|-----------------------|---------------|
| Configuration axis[1] | Axis0001      |
| Configuration axis[2] | Axis0002      |

### • Setting

| Item                                   | Setting value        |                      |
|----------------------------------------|----------------------|----------------------|
|                                        | Configuration axis 1 | Configuration axis 2 |
| Sub point                              | 40000.0              | 50000.0              |
| End point                              | 80000.0              | 30000.0              |
| Velocity                               | 50000.0              |                      |
| Acceleration                           | 50000.0              |                      |
| Deceleration                           | 50000.0              |                      |
| Jerk                                   | 0.0                  |                      |
| Circular interpolation error tolerance | 100.0                |                      |

## ■Axes

# 46.13 Relative Value Circular Interpolation Control

## MCv\_MoveCircularInterpolateRelative

This FB performs positioning with 2-axis circular interpolation using the configuration axes of the set axes group by setting the relative position from the current position at start to the end point and sub point.

| Ladder                                                                                                                                                                                                                                                                                                                                                                                                                                       | FBD/LD                                                                                                                                                                                                                                                                                                                                        | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Processing details

- This FB specifies an axes group and performs interpolation control mechanically so that the path from the start point (move start point) to the end point forms an arc for a linear axis which is orthogonally arranged.
- In circular interpolation control, interpolation control is performed using two arbitrary axes from the configuration axes set to the axes group.
- For circular interpolation control, the border point specification, center point specification, and radius specification circular interpolation methods are settable.
- In MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control), 2-axis circular interpolation control is performed by specifying the movement amount from the current position to the end point or sub point.

## Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Circular interpolation axis (CircAxes)

In circular interpolation control, circular interpolation is performed by using two arbitrary axes from the configuration axes set to the axes group.

The axes used to perform circular interpolation are specified from the configuration axes in the axes group by using Circular interpolation axis (CircAxes). The Circular interpolation axis (CircAxes) has two array elements. For the arrays, specify the index Nos. (1 to 16: configuration axis 1 to 16) of configuration axes to be used for interpolation control.

The first element of the array is regarded as the reference axis.

If the configuration axis specified does not have an axis set, Circular Interpolation Axis Unset (error code: 1ACAH) occurs.

### Ex.

When setting configuration axes 2 and 3 as the circular interpolation axes

```
CircAxes[0]:= 2;
```

```
CircAxes[1]:= 3;
```

## ■Circular interpolation mode (CircMode)

Sets the circular interpolation method (border point specification, center point specification, or radius specification) used to perform circular interpolation control.

The contents set in Sub point (AuxPoint) differ depending on the setting of Circular interpolation mode (CircMode).

| Setting value                               | Sub point (AuxPoint)                                                                                                                                                                                                                                                                 |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Border point specification<br>(mcBorder) | Sub point (AuxPoint) sets the border point on the arc connecting the start point and the end point.<br>Positioning control with arc path that passes through the specified border point is performed using the two configuration axes set in Circular interpolation axis (CircAxes). |
| 1: Center point specification<br>(mcCenter) | Sub point (AuxPoint) sets the center point of the arc.<br>Positioning control with an arc path having the center point at its center is performed using the two configuration axes set in Circular interpolation axis (CircAxes).                                                    |
| 2: Radius specification<br>(mcRadius)       | Sub point (AuxPoint) sets the radius of the arc.<br>Positioning control with an arc path having the specified radius is performed using the two configuration axes set in Circular interpolation axis (CircAxes).                                                                    |

For the operation of each circular interpolation control set in Circular interpolation mode (CircMode), refer to the following.

 User's manual for the controller used

## ■Sub point (AuxPoint)

Sets the position of the sub point (border point, center point, or radius) used to perform circular interpolation.

Sub point (AuxPoint) has 16 array elements. The contents set in Sub point (AuxPoint) differ depending on the setting of Circular interpolation mode (CircMode).

| Circular interpolation mode (CircMode)   | Setting range                   | Sub point (AuxPoint) setting                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Border point specification (mcBorder) | -10000000000.0 to 10000000000.0 | Sub point (AuxPoint) sets the border point on the arc connecting the start point and the end point.<br>AuxPoint[0..15] indicates the sub point position of configuration axis 1 to 16.<br><ul style="list-style-type: none"> <li>Sub point (AuxPoint) of configuration axes not set to the circular interpolation axes is ignored.</li> <li>Sub point (AuxPoint) of axes after all configuration axes set to the circular interpolation axes can be omitted.</li> </ul> |
| 1: Center point specification (mcCenter) |                                 | Sub point (AuxPoint) sets the center point of the arc.<br>AuxPoint[0..15] indicates the sub point position of configuration axis 1 to 16.<br><ul style="list-style-type: none"> <li>Sub point (AuxPoint) of configuration axes not set to the circular interpolation axes is ignored.</li> <li>Sub point (AuxPoint) of axes after all configuration axes set to the circular interpolation axes can be omitted.</li> </ul>                                              |
| 2: Radius specification (mcRadius)       | 0.000001 to 2147483647.0        | Sub point (AuxPoint) sets the radius of the arc.<br>AuxPoint[0] indicates the radius of the circle.<br><ul style="list-style-type: none"> <li>Inputs after AuxPoint[1] are ignored and can be omitted.</li> </ul>                                                                                                                                                                                                                                                       |

### Ex.

When setting configuration axis 2 and 3 to the circular interpolation axes and setting the relative position of the sub point for configuration axis 2 and 3 as 2000.0 and 3000.0

```
CircAxes[0]:= 2;
CircAxes[1]:= 3;
AuxPoint[0]:= 0.0;
AuxPoint[1]:= 2000.0;
AuxPoint[2]:= 3000.0;
AuxPoint[3]:= 0.0; *1
⋮
AuxPoint[15]:= 0.0; *1
```

\*1 "AuxPoint[3]:= 0.0; to AuxPoint[15]:= 0.0;" can be omitted.

## ■End point (EndPoint)

Sets the movement amount from the current position at start to the end point.

End point (EndPoint) has 16 array elements. EndPoint[0..15] indicates the end point position of configuration axis 1 to 16.

- End point (EndPoint) for configuration axes which are not set to the circular interpolation axis are ignored.
- End point (EndPoint) after all of the configuration axes which are set to the circular interpolation axis can be omitted.

## ■Path selection (PathChoice)

Sets the rotation direction for circular interpolation. For the rotation direction, the first element of the array set in Circular interpolation axis (CircAxes) is regarded as the reference axis. Path selection (PathChoice) is set when Circular interpolation mode (CircMode) is set to "1: Center point specification (mcCenter)" or "2: Radius specification (mcRadius)". When "0: Border point specification (mcBorder)" is set, this input is omitted.

The following shows the setting value, setting description, arc center angle that can be controlled, and path of Path selection (PathChoice) according to the setting of Circular interpolation mode (CircMode).

- Path for "1: Center point specification (mcCenter)"

| Setting value            | Setting description                                                                                                                                                                                                                                                                                                     | Arc center angle that can be controlled | Path |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|------|
| 0: CW (mcCW)             | CW                                                                                                                                                                                                                                                                                                                      | $0^\circ < \theta \leq 360^\circ$       |      |
| 1: CCW (mcCCW)           | CCW                                                                                                                                                                                                                                                                                                                     | $0^\circ < \theta \leq 360^\circ$       |      |
| 2: Shortcut (mcShortWay) | Shortcut <ul style="list-style-type: none"> <li>• When the start point, center point, and end point are on one straight line, becomes CW. (A semicircle is drawn in the CW direction.)</li> <li>• If the start point is the same as the end point, Path Choice Setting Incorrect (error code: 1B06H) occurs.</li> </ul> | $0^\circ < \theta \leq 180^\circ$       |      |
| 3: Detour (mcLongWay)    | Detour <ul style="list-style-type: none"> <li>• When the start point, center point, and end point are on one straight line, becomes CW. (A semicircle is drawn in the CW direction.)</li> <li>• When the start point is same as the end point, becomes CW. (A perfect circle is drawn in CW direction.)</li> </ul>      | $180^\circ \leq \theta \leq 360^\circ$  |      |

• Path for "2: Radius specification (mcRadius)"

| Setting value                | Setting description                                                                                                                          | Arc center angle that can be controlled | Path |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|------|
| 0: CW (mcCW)                 | CW<br>• If the start point, center point, and end point are on one straight line, Path Choice Setting Incorrect (error code: 1B06H) occurs.  | $0^\circ < \theta < 180^\circ$          |      |
| 1: CCW (mcCCW)               | CCW<br>• If the start point, center point, and end point are on one straight line, Path Choice Setting Incorrect (error code: 1B06H) occurs. | $0^\circ < \theta < 180^\circ$          |      |
| 4: CW Detour (mcCWLongWay)   | CW detour<br>• When the start point, end point, and center point are on one straight line, a semicircle is drawn.                            | $180^\circ \leq \theta < 360^\circ$     |      |
| 5: CCW Detour (mcCCWLongWay) | CCW detour<br>• When the start point, end point, and center point are on one straight line, a semicircle is drawn.                           | $180^\circ \leq \theta < 360^\circ$     |      |

## ■Velocity (Velocity)

Sets the maximum speed of the path used in MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control).

| Setting range                                |
|----------------------------------------------|
| 0.0, 0.0001 to 2500000000.0 <sup>*1</sup> *2 |

- \*1 To perform floating-point operation, the lower limit value of the command velocity is limited by the following restrictions.  
If the velocity converted from the command velocity to operation cycle is less than 0.00001, Out of Operation Cycle Converted Velocity Range (error code: 1B16H) (when changing the velocity, Out of Operation Cycle Converted Velocity Range Warning (event code: 00D2FH)) occurs. To improve the precision of floating-point operation, change Position command unit (AxisName.Pr.Unit\_Position) and Speed command unit (AxisName.Pr.Unit\_Velocity) and perform settings so that the velocity converted into the operation cycle is not less than "0.00001".
- \*2 When a Motion control FB with a commanded velocity of "0.0" performs a multiple start, the commanded velocity of the previous Motion control FB is used.

## ■Acceleration (Acceleration)

Sets the acceleration used in MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control).

The setting range differs depending on the setting for Acceleration/deceleration method setting (Options (Options): Bit 0 to 2).

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | 0.000000 <sup>*1</sup> , positive numbers from 0.000001 to 8400.0[s]                   |

- \*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Deceleration (Deceleration)

Sets the deceleration used in MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Deceleration (Deceleration) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                                          |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                               |

\*1 The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Jerk (Jerk)

Sets the jerk used in MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control).

Specifies the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) is set to "0: Acceleration/deceleration specification method (mcAccDec)". Jerk (Jerk) is not used if the acceleration/deceleration method is set to "1: Acceleration/deceleration time-fixed method (mcFixedTime)".

| Acceleration/deceleration method setting (Options (Options): Bit 0 to 2) | Setting range                                                           |
|--------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec)             | 0.0000, positive numbers from 0.0001 to 2147483647.0[U/s <sup>2</sup> ] |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime)             | Not used                                                                |

## ■Circular interpolation error tolerance (CircularErrorTolerance)

In circular interpolation control with center point specification, the arc path calculated from the start position and center position may deviate from the end position set in End point (EndPoint).

Circular interpolation error tolerance (CircularErrorTolerance) sets the allowable width of errors between the calculated arc path and the end position.

| Setting range                                                                      | Description                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Calculated error ≤ Circular interpolation error tolerance (CircularErrorTolerance) | <p>Circular interpolation control to the set end point address is performed while the error compensation is carried out by spiral interpolation.</p>  |
| Calculated error > Circular interpolation error tolerance (CircularErrorTolerance) | <p>At the positioning start, Circular Interpolation Error Allowable Value Over (error code: 1AD9H) occurs and the control will not start. The operation will immediately stop if the error is detected during positioning control.</p>    |

## ■ Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control).

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                                          |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                                    |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*<sup>1</sup> Stops are not performed between the under-control FB and the buffering FB.

### Point

For details on multiple start (buffer mode), refer to the following.

 User's manual for the controller used

■Options (Options)

The function options for MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                            | Description                                                                                                                                                                                                               |
|--------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 2 | Acceleration/<br>deceleration method<br>setting | Sets the acceleration/deceleration method used to perform control.<br>• 0: Acceleration/deceleration specification method (mcAccDec)<br>• 1: Acceleration/deceleration time-fixed method (mcFixedTime)                    |
| 3      | Position selection during<br>buffer mode        | Sets the position when executing relative positioning control by multiple start.<br>• 0: Set position<br>• 1: Actual position<br>* This bit is valid when setting "0: Aborting (mcAborting)" in Buffer mode (BufferMode). |

• Acceleration/deceleration method setting (Bit 0 to 2)

| Setting value                                                   | Description                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration<br>specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in MCv_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control).                                                                                                                      |
| 1: Acceleration/deceleration time-fixed<br>method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time specified in MCv_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control) regardless of the velocity. The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

- Position selection during buffer mode (Bit 3)

| Setting value      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Set position    | Performs relative positioning control from the set position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 1: Actual position | <p>Performs relative positioning control from the actual position. The sub point (border point, center point, and radius) and end point are calculated based on the actual position, and the set position is used as the start point.</p> <p>The operation for each type of Circular interpolation mode (CircMode) is shown below.</p> <p>■When "0: Border point specification (mcBorder)" is set</p> <p>The border point and end point is calculated based on the actual position. The center point is determined by the start point (set position), border point, and end point.</p>  <p>■When "1: Center point specification (mcCenter)" is set</p> <p>The center point and end point are calculated based on the actual position. The arc of the circle may be an elliptic circle in some cases.</p>  <p>■When "2: Radius specification (mcRadius)" is set</p> <p>The end point is calculated based on the actual position. The center point is determined by the start point (set position), radius, and end point.</p>  |

### ■Necessary object data

When using MCv\_MoveCircularInterpolateRelative (Relative Value Circular Interpolation Control), set the following object data for all configuration axes in the specified axes group.

- Target position (607AH)

If there is a configuration axis where object data is not set, Necessary Slave Object Unset (error code: 1AF7H) occurs and the axis will not start.

For details on object data settings, refer to the following.

 User's manual for the controller used

## Precautions

- Circular interpolation including an axis whose stroke limit is set to invalid cannot be performed. Software stroke limit invalid at circular interpolation (error code: 1ADAH) occurs and the operation does not start.
- When the interpolation path exceeds the stroke limit range during interpolation operation, Software stroke limit over (forward direction) (error code: 1A83H) or Software stroke limit over (reverse direction) (error code: 1A84H) occurs and the operation will stop.

### Ex.

When the upper limit of the software stroke limit is exceeded in the positive direction of the Y-axis

For an immediate stop, stops at the same time that the error occurs.

For a deceleration stop, decelerates to a stop along the arc of the circle as shown below.

## Program example

The following is a program example. The circular interpolation control start (bCircularInterpolateCMD) is set to TRUE, and Axes group 1 (AxesGroup001) is enabled. Then, 2-axis circular interpolation (sub point specification) relative positioning control is performed for Axis group 1 (AxesGroup001).

### • Operation

### • Axes group

| Item                  | Setting value |
|-----------------------|---------------|
| Configuration axis[1] | Axis0001      |
| Configuration axis[2] | Axis0002      |

### • Setting

| Item                                   | Setting value        |                      |
|----------------------------------------|----------------------|----------------------|
|                                        | Configuration axis 1 | Configuration axis 2 |
| Sub point                              | 30000.0              | 30000.0              |
| End point                              | 70000.0              | 10000.0              |
| Velocity                               | 50000.0              |                      |
| Acceleration                           | 50000.0              |                      |
| Deceleration                           | 50000.0              |                      |
| Jerk                                   | 0.0                  |                      |
| Circular interpolation error tolerance | 100.0                |                      |

## ■Axes

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |
| 2        | Axis0002   | AXIS_REF  | Axis 2  |

## ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

# 46.14 Cam Operation Start

46

## MC\_CamIn

This FB starts cam operation according to the specified cam data.

## Processing details

- This FB sets Master axis offset (MasterOffset), Slave axis offset (SlaveOffset), Master axis scaling (MasterScaling), Slave axis scaling (SlaveScaling), Master axis follow-up distance (MasterStartDistance), Master axis synchronization start position (MasterSyncPosition), Start mode (StartMode), Master axis data source selection (MasterValueSource), Cam tableID (CamTableID), and Buffer mode (BufferMode), and performs the cam operation.
- To stop the operation, perform MC\_Stop (Forced Stop).

### ■ Timing chart

- When the processing is completed successfully

When Start Mode (StartMode) is set to "1: Absolute (mcAbsolute)" and Master axis absolute coordinate (MasterAbsolute) set in MC\_CamTableSelect (Cam Table Selection) is "FALSE (Relative coordinate)"

\*1 Axis status of Slave axis (Slave)

- When the processing is completed with an error

For the timing chart, refer to the following.

☞ Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ Starting cam operation

By setting Start Mode (StartMode), the synchronization timing for cam operation and reflection timing for the cam control data can be set.

- Synchronization timing for cam operation

The following shows the synchronization timing for Current value per cycle (InputPerCycle), Reference value (Reference), and Output value (OutputData) based on Start mode (StartMode) and related parameters (Master axis synchronization start position (MasterSyncPosition) and Master axis follow-up distance (MasterStartDistance)).

| Start mode (StartMode)*1   | Timing for starting synchronization                                                                                                                                                                              |                             |                           |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|---------------------------|
|                            | Current value per cycle (InputPerCycle)                                                                                                                                                                          | Reference value (Reference) | Output value (OutputData) |
| 0: Immediate (mclmmediate) | Synchronization starts when MC_CamIn (Cam Operation Start) is executed.<br>Master axis synchronization start position (MasterSyncPosition) and Master axis follow-up distance (MasterStartDistance) are ignored. |                             |                           |
| 1: Absolute (mcAbsolute)   | Synchronization starts when the master axis position*2 passes Master axis synchronization start position (MasterSyncPosition)*3.<br>Master axis follow-up distance (MasterStartDistance) is ignored.             |                             |                           |

\*1 For details on Start mode (StartMode), refer to the following.

📖 Page 1812 Start mode (StartMode)

\*2 Set the position data to be used based on Specifying target of Master axis synchronization start position pass check (Options (Options): Bit 21). For details, refer to the following.

📖 Page 1819 Options (Options)

\*3 The position of the Master axis has crossed over Master axis synchronization start position (MasterSyncPosition)(or, the Master axis synchronization start position (MasterSyncPosition) + Master axis follow-up distance (MasterStartDistance)). When these values are the same, the Master axis is considered to have not passed, and should the Master axis move from this value, it will be considered to have passed.

- Timing of control change by FB restart/continuous update

The following shows the timing for reflecting changed parameters in control by FB restart/continuous update based on Start mode (StartMode).

| Start mode (StartMode)     | Timing for reflecting parameters                                                      |
|----------------------------|---------------------------------------------------------------------------------------|
| 0: Immediate (mclmmediate) | Immediate                                                                             |
| 1: Absolute (mcAbsolute)   | When the current value per cycle (InputPerCycle) passes the 1st point on the CamTable |

When the changed values exceed the range, the error is output and the control is maintained by keeping the value before.

| Parameter                           | Error                                                                                                                                                                                                                                                                                  |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master axis offset (MasterOffset)   | Out of Master axis offset range (error code: 1AAFH)                                                                                                                                                                                                                                    |
| Slave axis offset (SlaveOffset)     | Out of slave axis range (error code: 1AB0H)                                                                                                                                                                                                                                            |
| Master axis scaling (MasterScaling) | Out of master axis coefficient range (error code: 1AB1H)                                                                                                                                                                                                                               |
| Slave axis scaling (SlaveScaling)   | Out of slave axis coefficient range (error code: 1AB2H)                                                                                                                                                                                                                                |
| Cam table ID (CamTableID)           | <ul style="list-style-type: none"> <li>• When the Cam table ID (CamTableID) value is out of range</li> <li>Out of cam table ID range (error code: 1AAEH)</li> <li>• When there is no Cam table ID (CamTableID) open area</li> <li>No Cam Table warning (event code: 00D44H)</li> </ul> |

## ■Cam table information

For cam table information, the following shows the cam operation at execution of MC\_CamIn (Cam Operation Start) depending on the periodic mode, master axis absolute coordinate, and slave axis absolute coordinate set in MC\_CamTableSelect (Cam Table Selection).

○: Used in control, ×: Not used in control

- Slave axis absolute coordinate (SlaveAbsolute)

The following shows the cam operation depending on the setting of Slave axis absolute coordinate (SlaveAbsolute).

| Slave axis absolute coordinate (SlaveAbsolute) | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE (Relative coordinate)                    | <p>When In synchronization (InSync) becomes TRUE, the slave axis starts the operation of the cam table from the current position (set position).</p> <p>When Periodic (Periodic) of the cam table is set to "TRUE: Periodic", the next cycle starts from the stroke position (set position) where the last cycle completed.</p>  |

| Slave axis absolute coordinate (SlaveAbsolute) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRUE (Absolute coordinate)                     | <p>The cam is operated within the ring counter range including current values of the Slave axis (Slave) at the point when In synchronization (InSync) becomes TRUE.</p> <p>Command is output per operation cycle to return the set position of the Slave axis (Slave) to the start point of the cam table when In synchronization (InSync) and when the cam cycle completion (EndOfProfile) become TRUE. If the command at this time is too large, the position command and speed command to the drive unit also become too large, causing a servo error ("AL.035 (Command frequency error)") for the MR-J5(W)-G. The set position of the Slave axis (Slave) will not output any values outside the ring counter range.</p> <p>■When the Stroke Range is within the ring counter range of the Slave axis</p>  <p>■When the Stroke Range is within the ring counter range of the Slave axis (Cam started on the 2nd cycle)</p>  <p>■When the Stroke Range is outside the ring counter range of the Slave axis</p>  <p>■When current value per cycle is changed</p> <ul style="list-style-type: none"> <li>To compensate the Reference value (Reference) so that the Slave axis (Slave) does not operate, any range outside of the ring counter range will be changed. When the Slave axis (Slave) has moved and the current value per cycle has changed, change the Master axis offset (MasterOffset).</li> </ul>  |

- Length per cycle (CycleLength)

For the length per cycle, the input amount that is required for one cycle is set. For details, refer to the following.

☞ Page 1819 Current value per cycle (InputPerCycle)

- Stroke amount (Stroke)

For the stroke amount, the stroke amount corresponding to the stroke ratio at 100% is set. For details, refer to the following.

☞ Page 1821 Output value (OutputData)

- Start point (StartPoint) and Initial stroke amount (StartStroke)

The Start Point (StartPoint) used for cam operation and the Initial stroke amount (StartStroke) will differ depending on the Specifying interpolation method (Interpolate).

| Specifying interpolation method (Interpolate) | Cam operation Start Point                           | Cam operation initial stroke amount                  |
|-----------------------------------------------|-----------------------------------------------------|------------------------------------------------------|
| 0: Linear interpolation                       | Input value of the cam table 1st point              | Output value of the cam table 1st point              |
| 1: Specifying for each section                | Start Point (StartPoint) of the cam table 1st point | Initial stroke amount (StartStroke) of the cam table |
| 2: Spline interpolation                       |                                                     |                                                      |

#### ■ Cam operation Start Point

Operating with a Current value per cycle (InputPerCycle) of "0.0".

- Cam table

#### ■ Cam (1) (Cam operation start point "0.0")

- Interpolation method: Section interpolation
- Length per cycle: 360.0
- Start point: 0.0
- Initial stroke amount: 0.0

- Cam operation

The following describes operation of the program.

#### ■ Cam operation initial stroke amount

Operates so that the initial stroke amount equals the Output value (OutputData) at the start of synchronization. Because the initial stroke amount of the cam operation stops the Slave axis (Slave) from operating, the initial stroke amount from the reference axis (Reference) is decreased.

- When Initial stroke amount (StartStroke) of the cam operation is "0.0"

- When Initial stroke amount (StartStroke) of the cam operation is "25.0"

## ■ Master axis offset (MasterOffset)

Setting Master axis offset (MasterOffset) shifts the phase of Master axis (Master) by the offset amount. (This does not affect Master axis follow-up distance (MasterStartDistance) or Master axis synchronization start position (MasterSyncPosition).)

When a value other than "0.0" is set at operation start, the position of Master axis (Master) is changed at the rising edge of In synchronization (InSync) to the cam position per cycle position with the offset amount added. When this happens, the Reference value (Reference) is compensated so that the Slave axis (Slave) does not operate.

- When Start Mode (StartMode) is "0: Immediate (mclmmediate)"

- When Start Mode (StartMode) is "0: Immediate (mclmmediate)"

When the master axis offset (MasterOffset) is changed while In Synchronization (InSync) is TRUE, the position of the Slave axis (Slave) operates matching the current value per cycle with Master axis Offset (MasterOffset) added.

## ■ Slave axis offset (SlaveOffset)

This variable shifts the displacement of the slave axis (Slave) by the offset amount.

When a value other than "0.0" is set before the rising edge of In synchronization (InSync), the Reference value (Reference) is compensated so that the Slave axis (Slave) does not operate at the rising edge of In synchronization (InSync).

- When Start Mode (StartMode) is "0: Immediate (mclmmediate)"

When the slave axis offset (SlaveOffset) is changed while In Synchronization (InSync) is TRUE, the position of the Slave axis (Slave) operates matching the position with the offset amount added.

- When Start Mode (StartMode) is "0: Immediate (mclmmediate)"

### ■ Master axis scaling (MasterScaling)

Master axis scaling (MasterScaling) expands/reduces the cam table length per cycle.

When changing during synchronization, a command equal to the movement amount is output to adjust the position of Slave axis (Slave) to the position of the cam table.

### ■ Slave axis scaling (SlaveScaling)

Slave axis scaling (SlaveScaling) expands/reduces the stroke amount of the cam table.

When changing during synchronization, a command equal to the movement amount is output to adjust the position of Slave axis (Slave) to the position of the cam table.

■Start mode (StartMode)

Sets the synchronization timing for cam operation and reflection timing for the cam control data.

For details on the synchronous timing for cam operation, refer to the following.

📖 Page 1799 Starting cam operation

If a value outside the range is set, Out of Start Mode Range (error code: 1AB5H) occurs.

After Cam Operation Start (MC\_CamIn) is executed, Controlling (Active) becomes TRUE if Current value per cycle (InputPerCycle) is synchronized, and In synchronization (InSync) becomes TRUE if Output value (OutputData) is synchronized.

For details on the application example for each setting value, refer to "Cam operation" in the following manual.

📖 User's manual for the controller used

The following shows the operation depending on the setting of Slave axis absolute coordinate (SlaveAbsolute).

| Setting value                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1: Absolute (mcAbsolute) | <p>The slave axis moves after Execution command (Execute) is started and the master axis cumulative current position passes Master axis synchronization start position (MasterSyncPosition).</p> <p>Checking of whether the Master axis cumulative current position has passed the Master axis synchronization start position (MasterSyncPosition) begins at the point when the Slave axis status becomes "7: During synchronous operation (SynchronizedMotion)".</p> <div style="display: flex; justify-content: space-around;"> <div style="width: 45%;"> <p>■ When slave axis absolute coordinate (SlaveAbsolute) is set to "FALSE: Relative coordinate"</p> </div> <div style="width: 45%;"> <p>■ When slave axis absolute coordinate (SlaveAbsolute) is set to "TRUE: Absolute coordinate"</p> </div> </div> |

### ■ Master axis data source selection (MasterValueSource)

Slave axis (Slave) sets the position type of Master axis (Master) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis (Master) and Slave axis (Slave) are different.

Operates with the same value as the set value when specifying Actual value in Master axis data source selection (MasterValueSource) while an axis type other than real axis is set in Master axis (Master).

| Setting value                                  | Description                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                      | Uses the commanded position of the master axis in the previous operation cycle. |
| 2: Actual value (mcActualValue)                | Uses the actual position of the master axis in the previous operation cycle.    |
| 101: Latest set value (mcLatestSetValue)       | Uses the commanded position of the master axis in the current operation cycle.  |
| 102: Latest actual value (mcLatestActualValue) | Uses the actual position of the master axis in the current operation cycle.     |

### Point

When Master axis data source selection (MasterValueSource) is set to "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" and the master axis becomes servo OFF by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis data source selection (MasterValueSource) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

## ■ Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MC\_CamIn (Cam Operation Start).

The velocity for MC\_CamIn (Cam Operation Start) follows the synchronizing FB (the master axis) and this velocity changes immediately based on the master axis velocity and the set cam data when the FB is switched. The switching condition for each mode is shown below.

| Setting value            | Description                                                                                                                                                                                                                                       | Switching condition                              |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                       | Always                                           |
| 1: Buffered (mcBuffered) | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB. | When Cam cycle completion (EndOfProfile) is TRUE |

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

### • Under-control FB and buffering FB (MC\_CamIn (Cam Operation Start))

If MC\_CamIn (Cam Operation Start) is activated while the under-control FB is controlling the slave axis specified for MC\_CamIn (Cam Operation Start), the control of the slave axis switches to MC\_CamIn (Cam Operation Start). The timing of switching control depends on the buffer mode (BufferMode) set for the FB being controlled and MC\_CamIn (Cam Operation Start).

The speed in buffering FB (MC\_CamIn (Cam Operation Start) occurs when In synchronization (InSync) becomes TRUE.

When Start mode (StartMode) is set to a value other than "0: Immediate (mclImmediate)", In synchronization (InSync) does not become TRUE immediately after the FB starts so the velocity remains at 0 until Executing (Busy), Controlling (Active), and In synchronization (InSync) are all TRUE.

- Under-control FB (MC\_CamIn (Cam Operation Start)) and buffering FB (Buffer mode (BufferMode)) set to "0: Aborting (mcAborting)"

If another FB is activated for the slave axis specified for MC\_CamIn (Cam Operation Start) while MC\_CamIn (Cam Operation Start) is controlling the slave axis, control of the slave axis switches to the other FB. The timing of control switching depends on the buffer mode (BufferMode) of another FB. When "0: Aborting (mcAborting)" is specified, the control switches immediately.

- Under-control FB (MC\_CamIn (Cam Operation Start)) and buffering FB (Buffer mode (BufferMode)) set to "1: Buffered (mcBuffered)"

If another FB is activated for the slave axis specified for MC\_CamIn (Cam Operation Start) while MC\_CamIn (Cam Operation Start) is controlling the slave axis, control of the slave axis switches to the other FB. The timing of control switching depends on the buffer mode (BufferMode) of another FB. When "1: Buffered (mcBuffered)" is specified, the control switches at the end of the next cycle.

- Under-control FB (MC\_CamIn (Cam Operation Start)) and buffering FB (MC\_CamIn (Cam Operation Start))

If another MC\_CamIn (Cam Operation Start) is activated while MC\_CamIn (Cam Operation Start) is controlling the slave axis, control of the slave axis switches. When buffer mode (BufferMode) in another MC\_CamIn (Cam Operation Start) is "1: Buffered (mcBuffered)", the position of the start point is adjusted so that the end point and start point of the cam data are the same.

## Options (Options)

The function options for MC\_CamIn (Cam Operation Start) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name                                                                       | Description                                                                                                                                                                                                                                                                                                                                   |
|-----|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Specifying operation after one cycle operation                             | Specifies the operation after one cycle operation when Periodic (Periodic) of MC_CamTableSelect (Cam Table Selection) is set to "FALSE: Periodic". <ul style="list-style-type: none"> <li>0: End</li> <li>1: Wait for restart</li> </ul>                                                                                                      |
| 21  | Specifying target of Master axis synchronization start position pass check | Sets the target of the Master axis synchronization start position (MasterSyncPosition) pass check. <ul style="list-style-type: none"> <li>0: Master axis cumulative current position, or where the feedback position has been converted to the cumulative position.</li> <li>1: Master axis set position, or the feedback position</li> </ul> |

## Cam cycle completion (EndOfProfile)

After Controlling (Active) becomes TRUE, this variable becomes TRUE only for one execution cycle of the POU (Program Organization Unit) that calls FB each time movement equal to the cycle length occurs.

## Current value per cycle (InputPerCycle)

"0.0" is used as the initial value.

After Controlling (Active) becomes TRUE, the movement amount of Master axis (Master) is reflected as shown below.

Current value per cycle = (Master axis cumulative movement amount - Master axis offset + Current value per cycle change value) MOD Current value per cycle

The monitor value range is the following cam length per cycle range set in the cam table.

$0 \leq \text{Current value per cycle (InputPerCycle) of MC\_CamIn (Cam Operation Start)} < (\text{Cam length per cycle} \times \text{Master axis scaling})$

## ■Reference value (Reference)

When MC\_CamIn (Cam Operation Start) is executed, the reference value is calculated from the cam position start (cam current value per cycle) based on the set position where In synchronization (InSync) becomes TRUE.

- For subtracting the initial stroke amount in the cam table, the formula for initial values are shown below.

| Slave axis absolute coordinate (SlaveAbsolute)            | Formula                                                                                                                                                                                                                          |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE (Relative coordinate)<br>TRUE (Absolute coordinate) | Reference value = Slave axis position when synchronization starts - (Stroke value based on cam position (current value per cycle) when In synchronization (InSync) changes to TRUE + Initial stroke amount) × Slave axis scaling |
|                                                           | Reference value = The cumulative current position corresponding to the set position being 0 when In synchronization (InSync) changes to TRUE.                                                                                    |

- The reference values used in two-way cam operation and feed cam operation are shown below.

| Operation                                                                                                           | Description                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When Two-way cam operation, or Slave absolute coordinate (SlaveAbsolute) is "TRUE (Absolute Coordinate)"            | The reference value is not updated.                                                                                                                                                                                                                                                                                                 |
| When Feed cam operation as well as Slave axis absolute coordinate (SlaveAbsolute) are "FALSE (relative coordinate)" | <p>The reference value is calculated as shown below.</p> <ul style="list-style-type: none"> <li>Reference value = (Original reference value + (Stroke value at the last point - Stroke value at the 1st point) × Slave axis scaling)</li> </ul>  |

- The reference values are updated with the following timing.

| Update timing                                                                                                                 | Reference value calculation formula                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| When Current value per cycle (InputPerCycle) going in the address increasing direction passes the last point of the cam table | Original reference value + ((Stroke value at the last point - Stroke value at the 1st point) × Slave axis scaling)   |
| When Current value per cycle (InputPerCycle) going in the address decreasing direction passes the 1st point of the cam table  | Original reference value - ((Stroke value at the last point - Stroke value at the 1st point) × Slave axis scaling)   |
| When the current value per cycle is changed (Completion (Done) is TRUE for MCv_ChangeCycle (Current Value Change per Cycle))  | Original reference value - (Stroke value corresponding to current value per cycle after change × Slave axis scaling) |

## &lt;Reference value errors&gt;

Performing any of the following operations may cause a reference value error to occur.

- If the number of TRUE outputs by Cam cycle completion (EndOfProfile) exceeds the permissible value after the FeedCam as well as In synchronization (InSync) become TRUE. \*1
- If the FeedCam as well as the setting for the following control parameters contains a decimal.
  - (Stroke value at the last point - Stroke value at the 1st point) · Slave axis scaling
- If current value per cycle change is repeated with relative selection.

\*1 While an error does not occur if the positioning range exceeded count is less than the permissible value for the positioning range exceeded count, an error may occur if the permissible value is exceeded. (Operation is continued regardless of whether or not a truncation error has occurred.)

If the reference value error becomes too large, clear the synchronization status or reset it by executing a current value change with absolute position specification.

The permissible value for the positioning range exceeded count is a variable value calculated with the following formula.

Permissible value for the positioning range exceeded count = Limit value for the positioning range exceeded count / ((Output value at the last point - Output value at the 1st point) / slave scaling)

\*: The limit value for the positioning range exceeded count is the upper limit value of the positioning range, "1000000000".

(Example)

When the output value at the 1st point is "0", the output value at the last point is "1000000", and the output coefficient is "10", the permissible value for the positioning range exceeded count becomes "100000".

The monitor value range is shown below.

- Ring counter lower limit value of the slave axis ≤ Reference value < Ring counter upper limit value of the slave axis

## ■Output value (OutputData)

The default value is the initial stroke amount in the cam table.

The update timing and calculation method of Output value (OutputData) are as follows.

| Update timing                                                               | Output value calculation method                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| While Controlling (Active) is TRUE and In synchronization (InSync) is FALSE | Reference value + ((Initial stroke amount in the cam table + Slave axis offset) × Slave axis scaling)<br>When Start mode (StartMode) is set to Ramp-in (mcRampIn), the output value is calculated toward the slave axis position at the start of synchronization from the above position.<br>For details, refer to the following.<br>☞ Page 1812 Start mode (StartMode)                                                           |
| While In synchronization (InSync) is TRUE                                   | <p>■When Interpolation method is set to Section interpolation or Spline interpolation</p> <p>Reference value + ((Stroke amount × Stroke ratio corresponding to current value per cycle) + Slave axis offset) × Slave axis scaling</p> <p>■When Cam data format is set to Linear interpolation</p> <p>Reference value + ((Output value corresponding to cam current value per cycle) + Slave axis offset) × Slave axis scaling</p> |

## Precautions

- When Master axis offset (MasterOffset), Slave axis offset (SlaveOffset), Master axis scaling (MasterScaling), Slave axis scaling (SlaveScaling), or Cam table ID (CamTableID) are changed, the slave axis may move suddenly at the start of control or a control change. This sudden movement may cause a shock to the equipment, so it is important to carefully check the setting values and the change timing.
- When monitoring the axis being cam controlled with the engineering tool, the position, velocity, etc. is based on the unit setting of the axis. Units for the cycle length, stroke amount, etc. set in the operation profile data are not used.

## Program example

The following is a program example. The cam operation start command (bCamInStart) is set to TRUE, Axis 2 (Axis0002) is set as the master axis to be started in JOG operation, and cam operation of the slave axis (Axis0001) is performed according to the operation profile data (cam data 1).

## Processing details

- This FB sets Gear ratio numerator (RatioNumerator), Gear ratio denominator (RatioDenominator), Master axis data source selection (MasterValueSource), Acceleration (Acceleration), Deceleration (Deceleration), Jerk (Jerk), and Buffer mode (BufferMode), and starts the gear operation.
- To stop the operation, perform MC\_Stop (Forced Stop).
- After executing this FB, Slave axis (Slave) performs acceleration/deceleration until reaching the target velocity, the value of which is the velocity of Master axis (Master) converted by the gear ratio. After reaching the target velocity, Gear ratio reached (InGear) becomes TRUE, and Slave axis (Slave) is controlled using a velocity equal to the velocity of Master axis (Master) converted by the gear ratio.

\*1 Axis status of Slave axis (Slave)

- When the velocity of Master axis (Master) is changed during acceleration/deceleration, the gear synchronization speed is also updated.

■Timing chart

- When the processing is completed successfully

\*1 Axis status of Slave axis (Slave)

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

■Acceleration/deceleration until reaching the gear synchronization speed

- The acceleration/deceleration method for MC\_GearIn (Gear Operation Start) is the acceleration/deceleration specification method.
- Depending on the velocity and target velocity of the slave axis (Slave) at operation start, one of the following 4 types of acceleration/deceleration is performed. The type of acceleration/deceleration will not change even if the target velocity is updated during the acceleration/deceleration.

| Slave axis (Slave) velocity and target velocity                                                                                                | Acceleration/deceleration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## ■ Gear ratio numerator (RatioNumerator)/Gear ratio denominator (RatioDenominator)

Gear ratio numerator (RatioNumerator) and Gear ratio denominator (RatioDenominator) are set together.

Gear ratio numerator (RatioNumerator) sets the numerator value for converting and transmitting the velocity of Master axis (Master).

Gear ratio denominator (RatioDenominator) sets the denominator value for converting and composing the movement amount of Master axis (Master).

The velocity is converted as shown below.

$$\text{Master axis (Master) velocity after conversion} = \text{master axis (Master) velocity before conversion} \times \frac{\text{Gear ratio numerator (RatioNumerator)}}{\text{Gear ratio denominator (RatioDenominator)}}$$

- Set a positive value in Gear ratio denominator (RatioDenominator).
- The velocity direction can be reversed and transmitted by setting a negative value in Ratio numerator (RatioNumerator).  
The gear synchronization speed is changed if the gear ratio is changed during acceleration/deceleration. Therefore, the velocity of Slave axis (Slave) is changed directly and the gear operation may start because of the change of the gear synchronization speed.
- The velocity of Master axis (Master) after conversion can be set to "0" by setting the value of Gear ratio numerator (RatioNumerator) to "0".
- The target velocity is changed if the gear ratio is changed during acceleration/deceleration. Therefore, changing the target velocity may directly change the velocity of Slave axis (Slave) and start the gear operation.
  - Changing the gear ratio during acceleration/deceleration
    - Gear ratio increase (set to a value higher than the velocity of Slave axis (Slave))

- Gear ratio decrease (set to a value higher than the velocity of Slave axis (Slave))

- Gear ratio direction reverse (set the gear synchronization speed to a value lower than "0")

- When the gear ratio is changed during gear synchronization, the velocity of Slave axis (Slave) is changed directly.
  - Gear ratio change during gear synchronization

### Master axis data source selection (MasterValueSource)

Slave axis (Slave) sets the position type of Master axis (Master) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis (Master) and Slave axis (Slave) are different.

Operates with the same value as the set value when specifying Actual value in Master axis data source selection (MasterValueSource) while an axis type other than real axis is set in Master axis (Master).

| Setting value                                  | Description                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                      | Uses the commanded position of the master axis in the previous operation cycle. |
| 2: Actual value (mcActualValue)                | Uses the actual position of the master axis in the previous operation cycle.    |
| 101: Latest set value (mcLatestSetValue)       | Uses the commanded position of the master axis in the current operation cycle.  |
| 102: Latest actual value (mcLatestActualValue) | Uses the actual position of the master axis in the current operation cycle.     |

#### Point

When Master axis data source selection (MasterValueSource) is set to "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" and the master axis becomes servo OFF by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis data source selection (MasterValueSource) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

### Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following buffer modes are settable in MC\_GearIn (Gear Operation Start).

| Setting value            | Description                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                       |
| 1: Buffered (mcBuffered) | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB. |

#### Point

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

### Precautions

- When the gear ratio is changed, the velocity of the slave axis is changed directly. To smooth the speed change, use the buffer mode together with MCv\_SmoothingFilter (Smoothing Filter).
- When the velocity of Master axis (Master) after conversion is over the acceleration/deceleration time upper limit value during acceleration/deceleration operation, Acceleration Time Limit Over Warning (event code: 00D04H) or Deceleration Time Limit Over Warning (event code: 00D05H) will occur, the acceleration/deceleration operation is stopped, and the operation is restarted and continued at the velocity in the warning detection. If the warnings shown above occur, adjust the velocity of Master axis (Master) after conversion, Acceleration (Acceleration), and Deceleration (Deceleration) so that the setting for each does not exceed the acceleration/deceleration upper limit value.

## Program example

The following is a program example. The gear operation start command (bGearInStart) is set to TRUE, Axis 1 (Axis0001) is set as the master axis to be started in JOG operation, and gear operation of the slave axis (Axis0002) is performed according to the specified gear ratio.

- Setting

| Item                             |              | Setting value |
|----------------------------------|--------------|---------------|
| Data settings for gear operation | Acceleration | 5000.0        |
|                                  | Deceleration | 5000.0        |
|                                  | Jerk         | 0.0           |
| Data settings for JOG operation  | Velocity     | 1000.0        |
|                                  | Acceleration | 5000.0        |
|                                  | Deceleration | 5000.0        |
|                                  | Jerk         | 0.0           |

## ■Axes

| Axis No. | Label name | Data type | Comment |

# 46.16 Addition/Subtraction Positioning

46

## MC\_CombineAxes

This FB adds or subtracts the movement amounts of the two specified master axes and performs positioning using said value as the commanded position.

| Ladder                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | FBD/LD                                                                                                                                                                                                                                                                                                                                                                                        | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Processing details

- This FB sets Addition/subtraction method selection (CombineMode), Master axis 1 gear ratio numerator (GearRatioNumeratorM1), Master axis 1 gear ratio denominator (GearRatioDenominatorM1), Master axis 2 gear ratio numerator (GearRatioNumeratorM2), Master axis 2 gear ratio denominator (GearRatioDenominatorM2), Master axis 1 data source selection (MasterValueSourceM1), Master axis 2 data source selection (MasterValueSourceM2), and Buffer mode (BufferMode), and performs the addition/subtraction positioning.
- To stop the operation, perform MC\_Stop (Forced Stop).
- Combines the movement amounts of Master axis 1 (Master1) and Master axis 2 (Master2). In addition, a gear ratio can be set for each master axis. Combining the movement amounts adds or subtracts the numerical values regardless of the units of Master axis 1 (Master1) and Master axis 2 (Master2).

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ Addition/subtraction method selection (CombineMode)

Sets the method used to combine the movement amounts of Master axis 1 (Master1) and Master axis 2 (Master2).

Combining the movement amounts adds or subtracts the numerical values regardless of the units of Master axis 1 (Master1) and Master axis 2 (Master2).

| Setting value                                        | Description                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Add positions of 2 input axes<br>(mcAddAxes)      | <p>Adds the movement amounts of Master axis 1 (Master1) and Master axis 2 (Master2) and outputs the value.</p> <ul style="list-style-type: none"> <li>• Movement amount of Slave axis (Slave) = Movement amount of Master axis 1 (Master1) + Master axis 2 (Master2)</li> </ul>         |
| 1: Subtract positions of 2 input axes<br>(mcSubAxes) | <p>Subtracts the movement amount of Master axis 2 (Master2) from Master axis 1 (Master1) and outputs the value.</p> <ul style="list-style-type: none"> <li>• Movement amount of Slave axis (Slave) = Movement amount of Master axis 1 (Master1) - Master axis 2 (Master2)</li> </ul>  |

\*1 Axis status of Slave axis (Slave)

### ■ Master axis 1 gear ratio numerator (GearRatioNumeratorM1)/Master axis 1 gear ratio denominator (GearRatioDenominatorM1)

Master axis 1 gear ratio numerator (GearRatioNumeratorM1) and Master axis 1 gear ratio denominator (GearRatioDenominatorM1) are set together.

Master axis 1 gear ratio numerator (GearRatioNumeratorM1) sets the numerator value used when converting and combining the movement amount of Master axis 1 (Master1).

Master axis 1 gear ratio denominator (GearRatioDenominatorM1) sets the denominator value used when converting and combining the movement amount of Master axis 1 (Master1).

The movement amount is converted as shown below.

$$\text{Movement amount of the master axis 1 (Master1) after conversion} = \text{movement amount of the master axis 1 (Master1) before conversion} \times \frac{\text{Master axis 1 gear ratio numerator (GearRatioNumeratorM1)}}{\text{Master axis 1 gear ratio denominator (GearRatioDenominatorM1)}}$$

- Set a positive value in Master axis 1 gear ratio denominator (GearRatioDenominatorM1).
- The movement amount can be reversed and combined by setting a negative value in Master axis 1 gear ratio numerator (GearRatioNumeratorM1).
- To combine and have the movement amount of Master axis 1 (Master1) be "0" after conversion, set "0" as the setting value in Master axis 1 gear ratio numerator (GearRatioNumeratorM1).

### ■ Master axis 2 gear ratio numerator (GearRatioNumeratorM2)/Master axis 2 gear ratio denominator (GearRatioDenominatorM2)

Master axis 2 gear ratio numerator (GearRatioNumeratorM2) and Master axis 2 gear ratio denominator (GearRatioDenominatorM2) are set together.

Master axis 2 gear ratio numerator (GearRatioNumeratorM2) sets the numerator value used when converting and combining the movement amount of Master axis 2 (Master2).

Master axis 2 gear ratio denominator (GearRatioDenominatorM2) sets the denominator value used when converting and combining the movement amount of Master axis 2 (Master2).

The movement amount is converted as shown below.

$$\text{Movement amount of the master axis 2 (Master2) after conversion} = \text{movement amount of the master axis 2 (Master2) before conversion} \times \frac{\text{Master axis 2 gear ratio numerator (GearRatioNumeratorM2)}}{\text{Master axis 2 gear ratio denominator (GearRatioDenominatorM2)}}$$

- Set a positive value in Master axis 2 gear ratio denominator (GearRatioDenominatorM2).
- The movement amount can be reversed and combined by setting a negative value in Master axis 2 gear ratio numerator (GearRatioNumeratorM2).
- To combine and have the movement amount of Master axis 2 (Master2) be "0" after conversion, set "0" as the setting value in Master axis 2 gear ratio numerator (GearRatioNumeratorM2).

## ■ Master axis 1 data source selection (MasterValueSourceM1)/Master axis 2 data source selection (MasterValueSourceM2)

Slave axis (Slave) sets the position type of Master axis 1 (Master1) or Master axis 2 (Master2) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis 1 (Master1) or Master axis 2 (Master2) and Slave axis (Slave) are different.

Operates with the same value as the set value when specifying Actual value in Master axis 1 data source selection (MasterValueSourceM1) or Master axis 2 data source selection (MasterValueSourceM2) while an axis type other than real axis is set in Master axis 1 (Master1) or Master axis 2 (Master2).

| Setting value                                  | Description                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                      | Uses the commanded position of the master axis in the previous operation cycle. |
| 2: Actual value (mcActualValue)                | Uses the actual position of the master axis in the previous operation cycle.    |
| 101: Latest set value (mcLatestSetValue)       | Uses the commanded position of the master axis in the current operation cycle.  |
| 102: Latest actual value (mcLatestActualValue) | Uses the actual position of the master axis in the current operation cycle.     |

### Point

When Master axis 1 data source selection (MasterValueSourceM1) or Master axis 2 data source selection (MasterValueSourceM2) are set to "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" and the master axis becomes servo OFF by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis 1 data source selection (MasterValueSourceM1) or Master axis 2 data source selection (MasterValueSourceM2) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).  
The following buffer modes are settable in MC\_CombineAxes (Addition/Subtraction Positioning).  
The velocity of MC\_CombineAxes (Addition/Subtraction Positioning) follows the synchronizing FB (master axis) and changes immediately based on the master axis velocity and the set gear data when the FB is switched.

| Setting value            | Description                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                       |
| 1: Buffered (mcBuffered) | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB. |

Ex.

When linked start FB2 (Slave axis (Slave): MC\_CombineAxes (Addition/Subtraction Positioning)) has Buffer mode (BufferMode) set to "0: Aborting (mcAborting)" while FB1 is being executed

- When Addition/subtraction method selection (CombineMode) is set to "0: Add positions of 2 input axes (mcAddAxes)"

Velocity of FB2 occurs after In synchronization (InSync) becomes TRUE.

Point

For details on multiple start (buffer mode), refer to the following.  
📖 User's manual for the controller used

## Program example

The following is a program example. The addition/subtraction positioning start command (bCombineAxesStart) is set to TRUE, and positioning of the slave axis (Axis0001) is performed using the added/subtracted movement amount of the two master axes, Axis 2 (Axis0002) of the JOG 1 FB and Axis 3 (Axis0003) of the JOG 1 FB.

# 46.17 Backlash Compensation Filter

46

## MCv\_BacklashCompensationFilter

This FB performs filter processing that compensates the backlash amount in the machine system according to the movement direction.

| PurgedFilterPool | Disposed filter cumulated value | LREAL     | 0.0           | When Filter disable (FilterDisable) is set to TRUE, this variable stores the disposed value from Filter cumulated value (FilterPool).<br>Disposed filter cumulated value (PurgedFilterPool) is not cumulative.<br>The value is cleared to 0 at start of the FB. |

## Processing details

- This FB compensates for the backlash amount in the machine system.

- When the movement direction of Master axis (Master) is the same as Backlash compensation direction (BacklashDirection), Slave axis (Slave) synchronizes to the position equivalent to the Master axis (Master) current position shifted in the Backlash direction (BacklashDirection) by the value of Backlash amount (BacklashAmount). When the movement direction of Master axis (Master) is the reverse of Backlash compensation direction (BacklashDirection), Slave axis (Slave) synchronizes to the Master axis (Master) current position. Whenever the Master axis (Master) movement direction changes, backlash compensation is performed with the Slave axis (Slave) extra movement amount limited to only the value of Backlash amount (BacklashAmount).

- This section describes the stop operation specific to the backlash compensation filter.

When the stop factor occurs on Slave axis (Slave), Slave axis (Slave) starts the stop operation from the synchronous position. The compensated movement amount (the value from Filter cumulated value (FilterPool)) will not be restored to its original value.

- Operation at filter disabled (at Enable (Enable) falling edge)

Slave axis (Slave) stops immediately at the synchronous position upon reaching the Enable (Enable) falling edge. The compensated movement amount (the value from Filter cumulated value (FilterPool)) will not be restored to its original value.

### ■ Timing chart

- When the processing is completed successfully

\*1 "Analyzing" of Slave axis (Slave).

\*2 Axis status of Slave axis (Slave)

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1435 Basic operation of Enable (Enable) type motion control FBs

## ■ Backlash compensation direction (BacklashDirection)

Sets the backlash compensation direction.

Outputs the compensation amount to Slave axis (Slave) when the Master axis (Master) movement direction is the value of Backlash compensation direction (BacklashDirection).

When the backlash compensation filter is enabled (when starting the FB with Filter disable (FilterDisable) set to FALSE, or when Filter disable (FilterDisable) reaches the trailing edge during execution), compensates to the address increasing direction of the Master axis (Master) set position so that the backlash status of the machine system is in the following relation.

| Setting value                                                                                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1: Positive direction (mcPositiveDirection)</b><br>The address increasing direction of the set position<br>   | <p>When the movement direction of Master axis (Master) is the positive direction, Slave axis (Slave) synchronizes to the position equivalent to the Master axis (Master) current position shifted in the positive direction by the value of Backlash amount (BacklashAmount).</p>    |
| <b>2: Negative direction (mcNegativeDirection)</b><br>The address increasing direction of the set position<br> | <p>When the movement direction of Master axis (Master) is the negative direction, Slave axis (Slave) synchronizes to the position equivalent to the Master axis (Master) current position shifted in the negative direction by the value of Backlash amount (BacklashAmount).</p>  |

## ■ Master axis data source selection (MasterValueSource)

Slave axis (Slave) sets the position type of Master axis (Master) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis (Master) and Slave axis (Slave) are different.

| Setting value                            | Description                                                                     |
|------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                | Uses the commanded position of the master axis in the previous operation cycle. |
| 101: Latest set value (mcLatestSetValue) | Uses the commanded position of the master axis in the current operation cycle.  |

## Options (Options)

The function options for MCv\_Jog (JOG) are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit | Name                                   | Description                                                                                                                                                                                                                                                                                                                                                                                |
|-----|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16  | Enable filter initial status selection | Sets the initial status for when the backlash compensation filter is enabled (when starting the FB with Filter disable (FilterDisable) set to FALSE, or when Filter disable (FilterDisable) reaches the trailing edge during execution).<br>• 0: First compensation<br>*If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs and the function does not start. |

- Enable filter initial status selection (Bit 16)

| Setting value         | Description                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: First compensation | Regardless of the Master axis (Master) current direction when the filter is enabled, starts filter operation assuming that the position relation of the Master axis (Master) current position and the Slave axis (Slave) current position do not have the backlash compensation added. |

## Procedure for enabling the backlash compensation filter

This section describes the procedure for enabling the backlash compensation filter and a usage example. Perform this procedure after the machine position is established by homing, or when restarting the backlash compensation filter after cancelling it midway.

1. Move the real drive axis by operations such as homing or JOG operation, and maintain the status so that the backlash of the machine system is generated in only one direction as shown in the correct example below.

■Correct example

■Incorrect example

2. Match the Master axis (Master) set position with the real drive axis set position by using the current position change, etc.
3. Set Backlash compensation direction (BacklashDirection) so that it is the reverse direction of the direction that the real drive axis was moved to in Step 1., then start the backlash compensation filter. In addition, start any back part function blocks that are present.

## Precautions

- The backlash compensation is a function which the command direction and the backlash status should not change from the external force and other factors. Correct compensation will not be performed when this function is used in the following cases.
  - A machine that has external force constantly applied in one direction, such as a vertical axis
  - A mechanism (such as rack and pinion mechanism) in which the backlash amount changes depending on the machine position
- When the Master axis (Master) movement direction changes, Slave axis (Slave) moves only the value of Backlash amount (BacklashAmount) for one operation cycle. Depending on the value, it may exceed the command frequency that the speed limit value and the driver unit can accept, so connect the speed limit filter or the smoothing filter to the backlash compensation filter back part.
- The Slave axis (Slave) current position (such as set position, machine feed position, etc.) will be the position to which the value of Backlash amount (BacklashAmount) compensation is added. Backlash amount (BacklashAmount) compensation will not be added to the Master axis (Master) current position.
- If Filter disable (FilterDisable) is switched during operation, the Slave axis (Slave) velocity may change rapidly.
- After enabling the command filter, when the Master axis (Master) command is not transmitted to Slave axis (Slave) or the back part synchronous control FB because the stop factor occurred on Slave axis (Slave), the synchronous position relation deviates. Before enabling the command filter again, execute the synchronous positioning as needed.

## Program example

The following is a program example. The speed limit filter is connected to the output stage of the backlash compensation filter and the filter processing is performed.

# 46.18 Smoothing Filter

46

## MCv\_SmoothingFilter

This FB performs filter processing according to the specified frequency.

## Public variables

| Public variable  | Name                            | Data type | Default value | Description                                                                                                                                                                                                                                                     |
|------------------|---------------------------------|-----------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PurgedFilterPool | Disposed filter cumulated value | LREAL     | 0.0           | When Filter disable (FilterDisable) is set to TRUE, this variable stores the disposed value from Filter cumulated value (FilterPool).<br>Disposed filter cumulated value (PurgedFilterPool) is not cumulative.<br>The value is cleared to 0 at start of the FB. |

## Processing details

- This FB removes frequencies higher than the value set in Frequency (Frequency), and makes smooth acceleration/ deceleration waveforms.
- Smoothing filter outputs the result of filter processing executed for the Master axis (Master) value set in Master axis data source selection (MasterValueSource) to Slave axis (Slave).
- Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) is "7: During synchronous operation (SynchronizedMotion)" during smoothing filter execution.
- The time constant of smoothing is " $1/\text{Frequency (Frequency)}[\text{s}]$ ", and the acceleration time and deceleration time become longer by the amount of the smoothing time constant. When Frequency (Frequency) is 10[Hz], the smoothing time constant is " $0.1[\text{s}] = 100[\text{ms}]$ ".

- If a smoothing filter is started while Slave axis (Slave) is in another operation FB, the start request will be ignored, and Start Not Possible (error code: 1AFCH) occurs. Start the smoothing filter when Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) is "4: Standby (Standstill)".
- MC\_Stop (Forced Stop) is the only function block that can be multiple started during smoothing filter execution.

## Timing chart

- When the processing is completed successfully

\*1 Axis status of Slave axis (Slave)

- When the processing is completed with an error

For the timing chart, refer to the following.

Page 1435 Basic operation of Enable (Enable) type motion control FBs

## ■Filter disable (FilterDisable)

Sets the method used for the filter processing.

| Setting value | Description                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------|
| FALSE         | Operates according to the filter setting.                                                        |
| TRUE          | Disables the filter and transmits the Master axis (Master) input to Slave axis (Slave) as it is. |

- When Filter disable (FilterDisable) is set to TRUE, the value in Filter cumulated value (FilterPool) becomes "0.0" and the disposed value from Filter cumulated value (FilterPool) is stored in Disposed filter cumulated value (PurgedFilterPool).

## ■Frequency (Frequency)

Sets the frequency to suppress vibration.

The following shows the settable range for Frequency (Frequency).

| 1/Slave axis operation cycle[s] | Setting range                                  |
|---------------------------------|------------------------------------------------|
| 250.00 [Hz] or more             | 0.20 to 250.00 [Hz]                            |
| Less than 250.00 [Hz]           | 0.20 to (1/Slave axis operation cycle[s]) [Hz] |

- If a value outside the range is set in Frequency (Frequency), Out of Frequency Specification Range (error code: 1AE6H) occurs.
- Valid frequencies can be checked in Valid frequency (ValidFrequency).
- To change the frequency, change Frequency (Frequency) when Filter cumulated value (FilterPool) is "0.0". Even if it is changed in a status other than "0.0", the change will not be reflected until Filter cumulated value (FilterPool) becomes "0.0".
- Frequency (Frequency) cannot be changed to a frequency lower than Valid frequency (ValidFrequency). If a lower frequency is set, Out of Frequency Specification Range (error code: 1AE6H) occurs.
- Filter cumulated value (FilterPool) may become "0.0" while the master axis operates with the operation pattern which repeats positive/reverse rotation. When the value of Frequency (Frequency) is changed while the filter operation is not settled, the filter operation will be stopped in the middle. Thus, it causes the deviation between the master axis and the slave axis. To change Frequency (Frequency), check the master axis stop and wait for the filter time constant before changing.

■Filter purge (FilterPurge)

Sets the operation for when Enable (Enable) is set to FALSE and Filter cumulated value (FilterPool) is other than "0.0".

| Setting value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRUE          | <p>When Enable (Enable) becomes FALSE, the axis operates until Filter cumulated value (FilterPool) reaches "0.0" and then stops.</p> <p>The diagram for FilterPurge = TRUE shows the following behavior: When Enable transitions from TRUE to FALSE, the slave axis continues to operate until the FilterPool value reaches 0.0. The Master axis velocity profile is a trapezoid. The Slave axis velocity profile follows the Master axis velocity with a smoothing time constant. The FilterPool value starts at 0.0, increases during the acceleration phase, remains constant during the constant velocity phase, and then decreases back to 0.0 during the deceleration phase. The time taken for FilterPool to reach 0.0 after Enable becomes FALSE is indicated by a double-headed arrow labeled 'Smoothing time constant'.</p> |
| FALSE         | <p>When Enable (Enable) becomes FALSE, immediately stops the slave axis regardless of the Filter cumulated value (FilterPool) status.</p> <p>The diagram for FilterPurge = FALSE shows the following behavior: When Enable transitions from TRUE to FALSE, the slave axis stops immediately, regardless of the FilterPool value. The Master axis velocity profile is a trapezoid. The Slave axis velocity profile follows the Master axis velocity with a smoothing time constant. The FilterPool value starts at 0.0, increases during the acceleration phase, and remains constant during the constant velocity phase. When Enable becomes FALSE, the slave axis stops immediately, and the FilterPool value remains constant.</p>                                                                                                  |

## ■ Master axis data source selection (MasterValueSource)

Slave axis (Slave) sets the position type of Master axis (Master) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis (Master) and Slave axis (Slave) are different.

Operates with the same value as the set value when specifying Actual value in Master axis data source selection (MasterValueSource) while an axis type other than real axis is set in Master axis (Master).

| Setting value                                  | Description                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                      | Uses the commanded position of the master axis in the previous operation cycle. |
| 2: Actual value (mcActualValue)                | Uses the actual position of the master axis in the previous operation cycle.    |
| 101: Latest set value (mcLatestSetValue)       | Uses the commanded position of the master axis in the current operation cycle.  |
| 102: Latest actual value (mcLatestActualValue) | Uses the actual position of the master axis in the current operation cycle.     |

### Point

When Master axis data source selection (MasterValueSource) is set to "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" and the master axis becomes servo OFF by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis data source selection (MasterValueSource) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

## Precautions

- For the smoothing filter, the operation load increases as the filter level increases. A rough standard for the operation load when the filter level is 5000 is approximately 415 [ $\mu$ s].
- The filter level is calculated with the following formula. Digits after the decimal point are rounded/up down to the nearest integer. When the result of rounding is "0", the operation is carried out as 1 level.  
Filter level = (1 / frequency[Hz]) / operation cycle[s]
- The smoothing filter secures the memory to use for filter processing at start. The memory usage can be calculated with the following formula. If memory is insufficient, change Maximum RAM size (AddonSystem.PrConst.MT\_MotionControl\_AxisFilter.RamSizeMax) of Addon MotionControl\_AxisFilter parameter (Addon\_MotionControl\_AxisFilter).  
Memory usage = Filter level  $\times$  8 [Bytes]
- The operation error may increase when the movement amount of the master axis or the slave axis is large and the following case applies. Confirm the unit setting of the master axis and the slave axis and decrease the movement range. If the error increases, clear the synchronization status or execute the current value change of absolute position specification.
- When the total sum of the movement amount (the following formula) equivalent to filter level at control exceeds the number of significant digits which can be represented by double-precision floating-point (approximately 15 digits).

Filter level - 1

$$\sum_{i=0} (i \text{ Position of the master axis before the operation cycle} - \text{Position of the master axis at the start of control})$$

- If Filter disable (FilterDisable) is switched during operation, the Slave axis (Slave) velocity may change rapidly.
- After enabling the command filter, when the Master axis (Master) command is not transmitted to Slave axis (Slave) or the back part synchronous control FB because the stop factor occurred on Slave axis (Slave), the synchronous position relation deviates. Before enabling the command filter again, execute the synchronous positioning as needed.

## Program example

The following is a program example. The filter processing that changes the trapezoidal acceleration/deceleration to a smooth acceleration/deceleration waveform is performed.

### • Operation

### • Settings

| Item                            |              | Setting value |
|---------------------------------|--------------|---------------|
| Frequency                       |              | 10.00         |
| Data settings for speed control | Velocity     | 5000.0        |
|                                 | Acceleration | 100.0         |
|                                 | Deceleration | 100.0         |
|                                 | Jerk         | 0.0           |

# 46.19 Moving Direction Restriction Filter

46

## MCv\_DirectionFilter

This FB performs filter processing to restrict traveling for the set movement direction.

## ■Public variables

| Public variable  | Name                            | Data type | Default value | Description                                                                                                                                                                                                                                                     |
|------------------|---------------------------------|-----------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PurgedFilterPool | Disposed filter cumulated value | LREAL     | 0.0           | When Filter disable (FilterDisable) is set to TRUE, this variable stores the disposed value from Filter cumulated value (FilterPool).<br>Disposed filter cumulated value (PurgedFilterPool) is not cumulative.<br>The value is cleared to 0 at start of the FB. |

## Processing details

- This FB restricts the movement of the slave axis to one direction in relation to the master axis movement.
- Moving direction limit filter takes the result of filter processing executed for the Master axis (Master) value set in Master axis data source selection (MasterValueSource) and outputs it to Slave axis (Slave).
- Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) is "7: During synchronous operation (SynchronizedMotion)" during moving direction filter execution.
- If a moving direction limit filter is started while Slave axis (Slave) is in another operation FB, the start request will be ignored, and Start Not Possible (error code: 1AFCH) occurs. Start the moving direction limit filter when Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) is "4: Standby (Standstill)".
- MC\_Stop (Forced Stop) is the only function block that can be multiple started during smoothing filter execution.
- When setting Enable (Enable) to FALSE, perform this function block while the slave axis is in stop status. If Enable (Enable) is set to FALSE while the slave axis is in operation, the slave axis will stop immediately.

### ■ Timing chart

- When the processing is completed successfully

\*1 Axis status of Slave axis (Slave)

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1435 Basic operation of Enable (Enable) type motion control FBs

■Filter disable (FilterDisable)

Sets the method used for the filter processing.

| Setting value | Description                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------|
| FALSE         | Operates according to the filter setting.                                                        |
| TRUE          | Disables the filter and transmits the Master axis (Master) input to Slave axis (Slave) as it is. |

- When Filter disable (FilterDisable) is set to TRUE, the value in Filter cumulated value (FilterPool) becomes "0.0" and the disposed value from Filter cumulated value (FilterPool) is stored in Disposed filter cumulated value (PurgedFilterPool).

Ex.

When set as shown below

| Input pin                                  | Setting value                                              |
|--------------------------------------------|------------------------------------------------------------|
| Filter operation (Filter)                  | 4: Clamp (Without Ramp at Deceleration) (ClampWithoutRamp) |
| Positive direction limit (PositiveDisable) | FALSE (Not limited)                                        |
| Negative direction limit (NegativeDisable) | TRUE (Limited)                                             |

## ■Filter operation (Filter)

- Sets the slave axis operation at control based on the setting of Filter operation (Filter).

| Setting value                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Ignore (Ignore)                                         | <ul style="list-style-type: none"> <li>The movement direction is not restricted.</li> <li>Filter cumulated value (FilterPool) is not updated.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2: Truncate (Truncate)                                     | <ul style="list-style-type: none"> <li>The movement amount to the restricted direction is ignored and is not added to Filter cumulated value (FilterPool).</li> <li>The movement amount to the restricted direction will be truncated, and the position relation between the master axis and the slave axis will deviate by an amount equal to the movement amount to the restricted direction.</li> </ul> <p>&lt;Example&gt;<br/>When Positive direction limit (PositiveDisable) is FALSE, and Negative direction limit (NegativeDisable) is TRUE</p>  <p>The axis operation in the negative direction is limited.</p> <p>Not updated when the filter operation (Filter) is "2: Truncate (Truncate)"</p>                                                                                      |
| 4: Clamp (Without Ramp at Deceleration) (ClampWithoutRamp) | <ul style="list-style-type: none"> <li>The movement amount to the restricted direction is added to Filter cumulated value (FilterPool).</li> <li>Filter cumulated value (FilterPool) reflects the reverse direction movement. Thus, even if operation to the restricted direction is repeated, the position relation between the master axis and the slave axis will not deviate from that when the status of Filter cumulated value (FilterPool) is "0.0".</li> </ul> <p>&lt;Example&gt;<br/>When Positive direction limit (PositiveDisable) is FALSE (Not limited), and Negative direction limit (NegativeDisable) is TRUE (Limited)</p>  <p>Accumulates as a filter cumulative value and the value is reflected when the input movement amount in the permitted direction is reached.</p> |

- If a value outside the range is set in Filter operation (Filter), Out of Filter Operation Specification Range (error code: 1AE7H) occurs.

## ■ Master axis data source selection (MasterValueSource)

Slave axis (Slave) sets the position type of Master axis (Master) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis (Master) and Slave axis (Slave) are different.

Operates with the same value as the set value when specifying Actual value in Master axis data source selection (MasterValueSource) while an axis type other than real axis is set in Master axis (Master).

| Setting value                                  | Description                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                      | Uses the commanded position of the master axis in the previous operation cycle. |
| 2: Actual value (mcActualValue)                | Uses the actual position of the master axis in the previous operation cycle.    |
| 101: Latest set value (mcLatestSetValue)       | Uses the commanded position of the master axis in the current operation cycle.  |
| 102: Latest actual value (mcLatestActualValue) | Uses the actual position of the master axis in the current operation cycle.     |

### Point

When Master axis data source selection (MasterValueSource) is set to "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" and the master axis becomes servo OFF by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis data source selection (MasterValueSource) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

## Precautions

- If Filter disable (FilterDisable) is switched during operation, the Slave axis (Slave) velocity may change rapidly.
- After enabling the command filter, when the Master axis (Master) command is not transmitted to Slave axis (Slave) or the back part synchronous control FB because the stop factor occurred on Slave axis (Slave), the synchronous position relation deviates. Before enabling the command filter again, execute the synchronous positioning as needed.

## Program example

The following is a program example. The filter processing that restricts the direction of the cam operation is performed.

### • Operation

### • Settings

| Item           | Setting value |
|----------------|---------------|
| Cam ID setting | 1             |

### ■Axes

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001   | AXIS_REF  | Axis 1  |
| 2        | Axis0002   | AXIS_REF  | Axis 2  |
| 3        | Axis0003   | AXIS_REF  | Axis 3  |

### ■Labels used

| Label name               | Data type                           | Comment                                     |

## 46.20 Speed Limit Filter

### MCv\_SpeedLimitFilter

This FB performs filter processing to restrict to the velocity of the set limit value.

## ■Public variables

| Public variable  | Name                            | Data type | Default value | Description                                                                                                                                                                                                                                                     |
|------------------|---------------------------------|-----------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PurgedFilterPool | Disposed filter cumulated value | LREAL     | 0.0           | When Filter disable (FilterDisable) is set to TRUE, this variable stores the disposed value from Filter cumulated value (FilterPool).<br>Disposed filter cumulated value (PurgedFilterPool) is not cumulative.<br>The value is cleared to 0 at start of the FB. |

## Processing details

- This FB sets a specified control value to the input velocity of the master axis, and outputs the velocity of the set control value to the slave axis.
- Speed limit filter outputs the result of filter processing executed for the master axis (Master) value set in Master axis data source selection (MasterValueSource) to the slave axis (Slave).
- Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) is "7: During synchronous operation (SynchronizedMotion)" during speed limit filter execution.
- If a speed limit filter is started while Slave axis (Slave) is in another operation FB, the start request will be ignored, and Start Not Possible (error code: 1AFCH) occurs. Start the speed limit filter when Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) is "4: Standby (Standstill)".
- MC\_Stop (Forced Stop) is the only function block that can be multiple started during speed limit filter execution.
- When setting Enable (Enable) to FALSE, perform this function block while the slave axis is in stop status. If Enable (Enable) is set to FALSE while the slave axis is in operation, the slave axis will stop immediately.

## ■Timing chart

- When the processing is completed successfully

\*1 Axis status of Slave axis (Slave)

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1435 Basic operation of Enable (Enable) type motion control FBs

### ■Filter disable (FilterDisable)

Sets the method used for the filter processing.

| Setting value | Description                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------|
| FALSE         | Operates according to the filter setting.                                                        |
| TRUE          | Disables the filter and transmits the Master axis (Master) input to Slave axis (Slave) as it is. |

- When Filter disable (FilterDisable) is set to TRUE, the value in Filter cumulated value (FilterPool) becomes "0.0" and the disposed value from Filter cumulated value (FilterPool) is stored in Disposed filter cumulated value (PurgedFilterPool).

**Ex.**

When set as shown below

| Input pin                                               | Setting value                                              |
|---------------------------------------------------------|------------------------------------------------------------|
| Positive direction filter operation<br>(PositiveFilter) | 4: Clamp (Without Ramp at Deceleration) (ClampWithoutRamp) |

## ■Positive direction filter operation (PositiveFilter)/Negative direction filter operation (NegativeFilter)

- Sets the slave axis operation at control based on the setting of Positive direction filter operation (PositiveFilter) and Negative direction filter operation (NegativeFilter).

| Setting value                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 4: Clamp (Without Ramp at Deceleration) (ClampWithoutRamp) | <ul style="list-style-type: none"> <li>The amount exceeding the control value is cumulated as Filter cumulated value (FilterPool) and output later. The Filter cumulated value (FilterPool) output does not operate deceleration.</li> <li>When "0.0" is set as the control value, all the master axis input to the applicable direction will be cumulated as Filter cumulated value (FilterPool) and will not be output later to the slave axis. The cumulated amount will be subtracted by the reverse direction master axis input, and the slave axis will not operate until Filter cumulated value (FilterPool) is "0.0".</li> </ul> <p>■When Filter cumulated value is greater than the decelerated distance</p>  <p>■When Filter cumulated value is smaller than the decelerated distance</p>  |

- If a value outside the range is set in Filter operation (Filter), Out of Filter Operation Specification Range (error code: 1AE7H) occurs.

### ■ Master axis data source selection (MasterValueSource)

Slave axis (Slave) sets the position type of Master axis (Master) that will execute single axis synchronous control.

The operation may differ depending on the execution order of the FBs or if the operation cycles of Master axis (Master) and Slave axis (Slave) are different.

Operates with the same value as the set value when specifying Actual value in Master axis data source selection (MasterValueSource) while an axis type other than real axis is set in Master axis (Master).

| Setting value                                  | Description                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------|
| 1: Set value (mcSetValue)                      | Uses the commanded position of the master axis in the previous operation cycle. |
| 2: Actual value (mcActualValue)                | Uses the actual position of the master axis in the previous operation cycle.    |
| 101: Latest set value (mcLatestSetValue)       | Uses the commanded position of the master axis in the current operation cycle.  |
| 102: Latest actual value (mcLatestActualValue) | Uses the actual position of the master axis in the current operation cycle.     |

#### Point

When Master axis data source selection (MasterValueSource) is set to "1: Set value (mcSetValue)" or "101: Latest set value (mcLatestSetValue)" and the master axis becomes servo OFF by a servo alarm or forced stop, the amount of the value change may be too large. This can be prevented by setting Master axis data source selection (MasterValueSource) to "2: Actual value (mcActualValue)" or "102: Latest actual value (mcLatestActualValue)".

### Precautions

- If Filter disable (FilterDisable) is switched during operation, the Slave axis (Slave) velocity may change rapidly.
- After enabling the command filter, when the Master axis (Master) command is not transmitted to Slave axis (Slave) or the back part synchronous control FB because the stop factor occurred on Slave axis (Slave), the synchronous position relation deviates. Before enabling the command filter again, execute the synchronous positioning as needed.

## Program example

The following is a program example. The filter processing that restricts the velocity of the synchronous encoder is performed.

## 46.21 Axis Control Start Wait

46

### MCv\_MoveWait

This FB immediately performs the operation of the multiple-started motion FB for the specified axis by inputting an execution permission signal.

## ■Output variable

| Output variable  | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                            |
|------------------|-----------------------|------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done             | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when input detection of the signal set by ExecutionPermission (Execution permission signal) and AnalysisComplete (Analysis completion) become TRUE, indicating MCv_MoveWait (Axis control start wait) control is completed. |
| Busy             | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MCv_MoveWait (Axis control start wait) is being executed.                                                                                                                                                              |
| Active           | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MCv_MoveWait (Axis control start wait) is controlling the axis.                                                                                                                                                       |
| CommandAborted   | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution is aborted by another FB.                                                                                                                                                                                    |
| Error            | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                       |
| ErrorID          | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used          |
| AnalysisComplete | Analysis completion   | BOOL       | FALSE         | This variable becomes TRUE when the multiple-started motion FB analysis is complete.                                                                                                                                                                   |

## Processing details

- The axis operation of the multiple-started single axis control motion FB is immediately started when ExecutionPermission (Execution permission signal) is input.
- If another motion FB performs multiple start while MCv\_MoveWait (Axis control start wait) is in operation, the multiple-started FB is executed until analysis is complete and waits until ExecutionPermission (Execution permission signal) is input. The timing of completion of multiple-started FB analysis can be checked with AnalysisComplete (Analysis completion).
- Execute ExecutionPermission (Execution permission signal) after AnalysisComplete (Analysis completion) becomes TRUE.
- Axis status (AxisName.Md.AxisStatus) is "6: During continuous operation (ContinuousMotion)" until ExecutionPermission (Execution permission signal) is input.
- When ExecutionPermission (Execution permission signal) is input, the multiple-started FB is executed after one operation cycle from when the input signal is detected. At this time, Axis Status (AxisName.Md.AxisStatus) transits to the state according to the multiple-started FB.
- Input ExecutionPermission after AnalysisComplete becomes TRUE.

## ■ Timing chart

- When the processing is completed successfully

- (1) FB2 starts after one operation cycle when ExecutionPermission input is detected.  
 (2) Analysis of FB2 in progress  
 (3) Analysis of FB2 completed

- When the FB is completed with an error

For the timing chart, refer to the following.

📖 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ExecutionPermission (Execution permission signal)

Specify a signal used for clearing MCv\_MoveWait (Axis control start wait).

ExecutionPermission (Execution permission signal) is set with an MC\_INPUT\_REF structure. For details on MC\_INPUT\_REF structures, refer to the following.

📖 Page 1487 MC\_INPUT\_REF

The following table shows the setting range for the input signal (ExecutionPermission.Signal) set in ExecutionPermission (Execution permission signal).

The type of input signal (ExecutionPermission.Signal) is SIGNAL\_SELECT structure.

| Structure                     | Variable name                                      | Type                                                    | Setting range                                                                                                                                                                                              |

|                               | CompensationTime (Compensation time)* <sup>2</sup> | LREAL                                                   | -5.0 to 0.0[s]                                                                                                                                                                                             |
|                               | FilterTime (Filter time)                           | LREAL                                                   | 0.0 to 5.0[s]                                                                                                                                                                                              |

\*1 An external signal high-accuracy input cannot be used. If a signal for an external signal high-accuracy input is specified, operation is performed with the same accuracy as a normal signal.

\*2 If a value smaller than one operation cycle is specified for Compensation time (ExecutionPermission.Signal.CompensationTime), operation is performed as 0.0 (no compensation).

When [OBJ] is specified, if the target modification is omitted, the object set in the target axis specified by the operand axis (Axis) is referred. However, if the axis set to Axis (Axis) does not have a station address or a station address has not been set, External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H) will be output.

When the station referred to when [OBJ] is specified has the Axis Emulate function enabled and also has a set station address, the emulating object will be referred.

To correct the advancement of ExecutionPermission (Execution permission signal) or adjust the execution timing of the multiple-started motion FB, set Compensation time (ExecutionPermission.Signal.CompensationTime).

To prevent signal misdetection caused by the chattering of ExecutionPermission (Execution permission signal), set Filter time (ExecutionPermission.Signal.FilterTime).

When a signal that cannot be used for Signal name (ExecutionPermission.Signal.Source.Target) is used, one of the following errors will be output: External signal selection string incorrect (error code: 1B05H), External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H), or Add-on Signal IO internal error (error code: 1B33H, 1BD8H).

## Precautions

- Input ExecutionPermission (execution permission signal) after AnalysisComplete becomes TRUE. If no multiple-started motion FB exists or if analysis is not completed (when AnalysisComplete (Analysis completion) is FALSE), even if the input of ExecutionPermission (Execution permission signal) is detected, Done (Execution completion) does not become TRUE.
- Perform multiple start with the motion FB after Active (Executing) of MCv\_MoveWait (Axis control start wait) becomes TRUE. If an error occurs while MCv\_MoveWait (Axis control start wait) is being executed, a multiple-started motion FB may be executed without waiting for the input of ExecutionPermission (Execution permission signal).
- When using the mixed operation cycles function, the operation cycle of the MCv\_MoveWait (Axis control start wait) target axis and the refresh cycle of ExecutionPermission (Execution permission signal) must be the same. If the refresh cycle is different, the positioning start timing may become irregular.
- To start axes with different operation cycles at the same time, set the same operation cycle to each axis. Otherwise, the axis start timing may deviate by one operation cycle. To start axes with different operation cycles at the same time, use multiple signals of ExecutionPermission (Execution permission signal) with the same Signal name (ExecutionPermission.Signal.Source.Target) and the same Signal logic (ExecutionPermission.Signal.Detection) set, and adjust the Compensation time (ExecutionPermission.Signal.CompensationTime).
- When executing MCv\_MoveWait (axis control start wait), check that Axis Status (AxisName.Md.AxisStatus) is "4: Standby (Standstill)". If Axis status (AxisName.Md.AxisStatus) is unable to start, Start Not Possible (error code: 1AFCH) occurs, and control in operation stops.
- If MCv\_MoveWait (axis control start wait) is started while another operation system FB is running, the start request will be ignored and Start during Operation Warning (event code: 00D01H) will occur.
- Set Buffered to Buffer mode (BufferMode) for the multiple start motion FB. If multiple start is performed by setting Aborting, MCv\_MoveWait (Axis control start wait) is aborted, the input status of ExecutionPermission (Execution permission signal) is ignored, and the multiple-started motion FB is executed immediately. If multiple start is performed when Blending is set, BufferMode specification not allowed (Error code: 1AE5H) occurs.

## Program example

The following is a program example. By setting Control start (bExecute) to TRUE, MC\_MoveRelative and MCv\_MoveLinearInterpolateRelative are analyzed and put in standby, and by setting Execution permission signal (bExecutionPermission) to TRUE, the FBs that are in standby mode are started at the same time.

## 46.22 Axes Group Control Start Wait

### MCv\_GroupMoveWait

This FB immediately performs the operation of the multiple-started motion FB for the specified axes group by inputting an execution permission signal.

## ■Output variable

| Output variable  | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                                 |
|------------------|-----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done             | Execution completion  | BOOL       | FALSE         | This variable becomes TRUE when the input of the signal set by ExecutionPermission (Execution permission signal) and AnalysisComplete (Analysis completion) become TRUE, indicating MCv_GroupMoveWait (Axes group control start wait) control is completed. |
| Busy             | Executing             | BOOL       | FALSE         | This variable becomes TRUE when MCv_GroupMoveWait (Axes group control start wait) is being executed.                                                                                                                                                        |
| Active           | Controlling           | BOOL       | FALSE         | This variable becomes TRUE while MCv_GroupMoveWait (Axes group control start wait) is controlling the axes.                                                                                                                                                 |
| CommandAborted   | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution is aborted by another FB.                                                                                                                                                                                         |
| Error            | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                            |
| ErrorID          | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used               |
| AnalysisComplete | Analysis completion   | BOOL       | FALSE         | This variable becomes TRUE when the multiple-started motion FB analysis is complete.                                                                                                                                                                        |

## Processing details

- The axes group operation of a multiple-started multi-axis control motion FB is immediately executed when ExecutionPermission (Execution permission signal) is input.
- If another motion FB performs multiple start while MCv\_GroupMoveWait (Axes group control start wait) is in operation, the multiple-started FB is executed until analysis is complete and waits until ExecutionPermission (Execution permission signal) is input. The timing of completion of multiple-started FB analysis can be checked with AnalysisComplete (Analysis completion).
- Execute ExecutionPermission (Execution permission signal) after AnalysisComplete (Analysis completion) becomes TRUE.
- Axes group status (AxisGroupName.Md.GroupStatus) is "5: Operating (GroupMoving)" until ExecutionPermission (Execution permission signal) is input.
- When ExecutionPermission (Execution permission signal) is input, the multiple-started FB is executed after one operation cycle from when the input signal is detected.
- Input ExecutionPermission after AnalysisComplete becomes TRUE.

## ■ Timing chart

- When the processing is completed successfully

- (1) FB2 starts after one operation cycle when ExecutionPermission input is detected.  
 (2) Analysis of FB2 in progress  
 (3) Analysis of FB2 completed

- When the FB is completed with an error

For the timing chart, refer to the following.

☞ Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■ExecutionPermission (Execution permission signal)

Specify a signal used for clearing MCv\_GroupMoveWait (Axes group control start wait).

ExecutionPermission (Execution permission signal) is set with an MC\_INPUT\_REF structure. For details on MC\_INPUT\_REF structures, refer to the following.

📖 Page 1487 MC\_INPUT\_REF

The following table shows the setting range for the input signal (ExecutionPermission.Signal) set in ExecutionPermission (Execution permission signal).

The type of input signal (ExecutionPermission.Signal) is SIGNAL\_SELECT structure.

| Structure                     | Variable name                                      | Type                                                    | Setting range                                                                                                                                                         |
|-------------------------------|----------------------------------------------------|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                               | Detection (Signal detection method)                | INT<br>(MC_SIGNAL_LOGIC)<br>📖 Page 1524 MC_SIGNAL_LOGIC | <ul style="list-style-type: none"> <li>• 0: Detection at TRUE (HighLevel)</li> <li>• 1: Detection at FALSE (LowLevel)</li> </ul>                                      |
|                               | CompensationTime (Compensation time)* <sup>2</sup> | LREAL                                                   | -5.0 to 0.0[s]                                                                                                                                                        |
|                               | FilterTime (Filter time)                           | LREAL                                                   | 0.0 to 5.0[s]                                                                                                                                                         |

\*1 An external signal high-accuracy input cannot be used. If a signal for an external signal high-accuracy input is specified, operation is performed with the same accuracy as a normal signal.

\*2 If a value smaller than one operation cycle is specified for Compensation time (ExecutionPermission.Signal.CompensationTime), operation is performed as 0.0 (no compensation).

When [OBJ] is specified, if the target modification is omitted, External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H) is output.

When the station referred to when [OBJ] is specified has the Axis Emulate function enabled and also has a set station address, the emulating object will be referred.

To correct the advancement of ExecutionPermission (Execution permission signal) and adjust the execution timing of the multiple-started motion FB, set Compensation time (ExecutionPermission.Signal.CompensationTime).

To prevent signal misdetection caused by the chattering of ExecutionPermission (Execution permission signal), set Filter time (ExecutionPermission.Signal.FilterTime).

When a signal that cannot be used for Signal name (ExecutionPermission.Signal.Source.Target) is used, one of the following errors will be output: External signal selection string incorrect (error code: 1B05H), External signal selection incorrect (error code: 1B31H, 1B32H, 1BD6H, or 1BD7H), or Add-on Signal IO internal error (error code: 1B33H, 1BD8H).

## Precautions

- Input ExecutionPermission (execution permission signal) after AnalysisComplete becomes TRUE. If no multiple-started motion FB exists or if analysis is not completed (when AnalysisComplete (Analysis completion) is FALSE), even if the input of ExecutionPermission (Execution permission signal) is detected, Done (Execution completion) does not become TRUE.
- Perform multiple start with the motion FB after Active (Executing) of MCv\_GroupMoveWait (Axes group control start wait) becomes TRUE. If an error occurs while MCv\_GroupMoveWait (Axes group control start wait) is being executed, a multiple-started motion FB may be executed without waiting for the input of ExecutionPermission (Execution permission signal).
- When using the mixed operation cycles function, the operation cycle of the MCv\_GroupMoveWait (Axes group control start wait) target axis and the refresh cycle of ExecutionPermission (Execution permission signal) must be the same. If the refresh cycle is different, the positioning start timing may become irregular.
- To start axes with different operation cycles at the same time, set the same operation cycle to each axis. Otherwise, the axis start timing may deviate by one operation cycle. To start axes with different operation cycles at the same time, use multiple signals of ExecutionPermission (Execution permission signal) with the same Signal name (ExecutionPermission.Signal.Source.Target) and the same Signal logic (ExecutionPermission.Signal.Detection) set, and adjust the Compensation time (ExecutionPermission.Signal.CompensationTime).
- When executing MCv\_GroupMoveWait (Axes group control start wait), check that Axes group status (AxisGroupName.Md.GroupStatus) is "4: Standby (GroupStandby)". If Axes group status (AxisGroupName.Md.GroupStatus) is unable to start, Start Not Possible (error code: 1AFCH) occurs, and control in operation stops.
- If MCv\_GroupMoveWait (axes group control start wait) is started while another operation system FB is running, the start request will be ignored and Start during Operation Warning (event code: 00D01H) will occur.
- Set Buffered to Buffer mode (BufferMode) for the multiple start motion FB. If multiple start is performed by setting Aborting, MCv\_GroupMoveWait (Axes group control start wait) is aborted, the input status of ExecutionPermission (Execution permission signal) is ignored, and the multiple-started motion FB is executed immediately. If multiple start is performed when Blending is set, BufferMode specification not allowed (Error code: 1AE5H) occurs.

## Program example

The following is a program example. By setting Control start (bExecute) to TRUE, MC\_MoveRelative and MCv\_MoveLinearInterpolateRelative are analyzed and put in standby, and by setting Execution permission signal (bExecutionPermission) to TRUE, the FBs that are in standby mode are started at the same time.

### ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|

# 46.23 Advanced Synchronous Control

46

## MCv\_AdvancedSync

This FB starts synchronous control according to the specified advanced synchronous control settings.

### Restriction

Before using this FB, check the versions of the controller and engineering tool.

 User's manual for the controller used

## Processing details

- When this FB is executed, it starts advanced synchronous control according to the specified advanced synchronous control settings.
- Synchronous control can only be started when Axis status (AxisName.Md.AxisStatus) of the slave axis is "4: Standby (Standstill)". When control is started, Axis status (AxisName.Md.AxisStatus) of the slave axis changes to "7: During synchronous operation (SynchronizedMotion)". When synchronous control is started, if "4: Standby (Standstill)" is not set, Axis status (AxisName.Md.AxisStatus) of the slave axis becomes "1: Stopping on error (ErrorStop)" and Start not possible (error code: 1AFCH) occurs.
- If Enable (Enable) of this FB is set to FALSE, or a stop cause occurs in the axis set in the axis information on the output axis, Slave axis (Slave) immediately stops or is decelerated to stop according to the stop cause and its stop processing.
- For details on advanced synchronous control, refer to the following.

📖 User's manual for the controller used

### ■ Timing chart

- When the processing is completed successfully

- When I/O variables are abnormal

- When an input variable is abnormal

## ■Deceleration (Deceleration)

The deceleration is set.

Specify the setting range if Acceleration/deceleration method setting (Options (Options): Bit 0 to 1) is set to "0: Acceleration/deceleration specification method (mcAccDec)".

| Acceleration/deceleration method setting<br>(Options (Options): Bit 0 to 1) | Setting range                                                                           |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method<br>(mcAccDec)             | 0.0000 <sup>*1</sup> , positive numbers from 0.0001 to 2147483647.0 [U/s <sup>2</sup> ] |

<sup>\*1</sup> The operation performed at start varies depending on the setting of Operation selection at start acceleration/deceleration 0 (AxisName.Pr.AccelerationZeroBehavior). When changing the acceleration or deceleration, the changes are not accepted.

## ■Options (Options)

The function options for this FB are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

<sup>\*1</sup> Set empty areas to "0".

| Bit | Name                                      | Description                                                                                                                          |
|-----|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Acceleration/deceleration method setting  | Sets the acceleration/deceleration method used to perform control.<br>• 0: Acceleration/deceleration specification method (mcAccDec) |

• Acceleration/deceleration method setting (bit 0 to 1)

| Setting value                                                | Description                                                                          |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Deceleration (Deceleration) set in this FB |

## Precautions

- Even if a stop cause occurs in an axis set to the input axis information of Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), or Sub-input axis (AdvOutputName.Pr.SubAxis) while this FB is being executed, Slave axis (Slave) maintains control under the command transmitted from the input axis. The axis status of Slave axis (Slave) does not change. Also, even if a stop cause occurs in an axis set to Axis information (AdvOutputName.Axis) of the output axis, the axis set to Axis information (AdvInputName.Axis) of the input axis is not affected.
- When this FB is started, Master axis and slave axis cyclic reference (error code: 1AADH) occurs in the following cases.

### Error occurrence condition

When multiple axes are concatenated, Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), and Sub-input axis (AdvOutputName.Pr.SubAxis) are set to Slave axis (Slave) of the single axis synchronous control FB in the later part.

257 or more single axis synchronous control FBs are concatenated.

- If Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), or Sub-input axis (AdvOutputName.Pr.SubAxis) becomes serve OFF due to a servo alarm or emergency stop, Slave axis (Slave) may operate unexpectedly. Therefore, using MC\_Stop (Forced Stop) to stop the operation of this FB is recommended.
- When the input axis is operated before Axis status (AxisName.Md.AxisStatus) of Slave axis (Slave) being analyzed for starting this FB becomes "7: During synchronous operation (SynchronizedMotion)", the information on the input axis being analyzed, such as the movement amount and the amount of change due to changes in the current value or other factors, will be reflected immediately after the start of synchronous control. The output axis may suddenly accelerate depending on the amount of movement or change in the input axis. Therefore, start the operation of the input axis after checking that synchronous control is active.
- If the setting values of the member variables ADV\_INPUT and ADV\_OUTPUT, which are imported during synchronous control, are changed to values outside the range during the execution of this FB, Out of Parameter Range (Advanced synchronous control input axis) or Out of Parameter Range (Advanced synchronous control output axis) occurs, and the control continues with the setting value before the change.
- When the setting values of the member variables ADV\_INPUT and ADV\_OUTPUT are outside the range at the start of this FB, Out of Parameter Range (Advanced synchronous control input axis) or Out of Parameter Range (Advanced synchronous control output axis) occurs, and the operation will not start.
- When this FB is started, Operation cycle mismatch (error code: 1B29H) occurs in the following cases. Even when MCV\_SyncOperationCycles (Control operation cycle synchronization) is used, Operation cycle mismatch (error code: 1B29H) occurs if the following conditions are satisfied.

### Error occurrence condition

The control operation cycles of Master axis (Master), Auxiliary axis (AdvOutputName.Pr.AuxAxis), and Sub-input axis (AdvOutputName.Pr.SubAxis) do not match that of the Slave axis (Slave).

The control operation cycle of the output axis does not match the refresh cycle of the clutch signals.

## Program example

For a program example of this FB, refer to the following manual.

 User's manual for the controller used

# 46.24 Multiple Axes Positioning Data Operation

46

## MCv\_MovePositioningData

This FB operates the axes group according to the specified positioning data.

Before using this FB, check the versions of the controller and engineering tool.

User's manual for the controller used

| InstanceID       | Instance ID              | INSTANCE_ID           | 0             | The instance ID is stored.<br>This variable is automatically set by the system when an instance is created.                                                                                                                                                                                                               |
| ResetMcode       | M code reset             | BOOL                  | FALSE         | When this variable is set to TRUE, the M code is reset.<br>M strobe (Mstrobe) becomes FALSE after the reset.                                                                                                                                                                                                              |
| Mstrobe          | M strobe                 | BOOL                  | FALSE         | This variable becomes TRUE when the M code output is valid.<br>This variable becomes TRUE at the M code output timing (Options (Options): Bit 16).<br>This variable becomes FALSE when M code reset (ResetMcode) is TRUE.                                                                                                 |
| ValidMcode       | Valid M code             | WORD (UINT)           | 0             | The valid M code (that is output in the latest status) is stored.<br>When the M code output for the positioning data is valid, the M code is updated to that of the positioning data number at the M code output timing (Options (Options): Bit 16).<br>*: The value is not reset when M code reset (ResetMcode) is TRUE. |
| StepMode         | Step mode                | INT<br>(MC_STEP_MODE) | 0             | The step mode is set.<br>• 0: Ignored (Ignored)<br>• 1: Deceleration Unit Step (StepPerDec)<br>• 2: Positioning Data Unit Step (StepPerPositioningData)<br>For details, refer to the following.<br> Page 1912 Step mode (StepMode)     |
| CurrentProfileNo | Executing profile number | WORD (UINT)           | 0             | The profile ID number currently being executed is stored.<br>For details, refer to the following.<br> Page 1913 Executing profile number (CurrentProfileNo)                                                                            |

- The following table shows the cycles at which public variables are imported or updated.

| Public variable  | Import/update cycle                                                   |
|------------------|-----------------------------------------------------------------------|
| InstanceID       | Execution cycle of a POU (Program Organization Unit) that calls an FB |
| ResetMcode       | Control cycle of an axes group structuring axis <sup>*1</sup>         |
| Mstrobe          |                                                                       |
| ValidMcode       |                                                                       |
| StepMode         |                                                                       |
| CurrentProfileNo | Execution cycle of a POU (Program Organization Unit) that calls an FB |

<sup>\*1</sup> The output variable may not always match the update timing. To adjust the update timing, call an FB from a program in the same cycle.

## Processing details

- The continuous positioning operation specified by the operation profile data (in the format of multiple axes positioning data) is performed on the axes group.
- In the multiple axes positioning data operation, the positioning data is read in ascending order starting from Start positioning data number (StartDataNo), and the multiple axes positioning operations are internally executed continuously.
- For details on the multiple axes positioning data operation, refer to the following.

📖 User's manual for the controller used

## ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

📖 Page 1435 Basic operation of Enable (Enable) type motion control FBs

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following table shows the buffer modes that can be set for this FB.

| Setting value            | Description                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                       |
| 1: Buffered (mcBuffered) | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB. |

### Point

For details on multiple start (buffer mode), refer to the following.

📖 User's manual for the controller used

## ■Options (Options)

The function options for this FB are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than 0 is set, Out of options range (error code: 1ABBH) occurs.

| Bit | Name                 | Description                                                                       |
|-----|----------------------|-----------------------------------------------------------------------------------|
| 16  | M code output timing | The timing for outputting the M code is set.<br>• 0: WITH Mode<br>• 1: AFTER Mode |

• M code output timing (Bit 16)

| Setting value   | Description                                                                                                                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: WITH Mode*2  | M strobe (Mstrobe) is set to TRUE when the positioning data starts positioning, and M code (Mcode) of the positioning data is stored in Valid M code (ValidMcode).                                            |
| 1: AFTER Mode*2 | M strobe (Mstrobe) is set to TRUE when the target position is reached (or after the setting time has elapsed when the dwell time is set), and the M code of the positioning data is stored in M code (Mcode). |

\*2 For details on each mode, refer to the following manual.

📖 User's manual for the controller used

## ■Step mode (StepMode)

The step mode is set.

| Setting value                                          | Description                                                                                 |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------|
| 0: Ignored (Ignored)                                   | The step function is disabled.<br>The step mode is ignored.                                 |
| 1: Deceleration Unit Step (StepPerDec)                 | The step function is enabled.<br>The step operation is performed at each deceleration.      |
| 2: Positioning Data Unit Step (StepPerPositioningData) | The step function is enabled.<br>The step operation is performed for each positioning data. |

## ■Executing profile number (CurrentProfileNo)

The profile ID number currently being executed is stored.

- This variable indicates that the operation profile data in the open area that is associated with the profile ID number is in use.
- The profile ID number is stored at the start of operation and cleared to 0 at the completion of the operation.

■When the FB is normal

■When an error occurred after the start of operation

- The stored value of Executing profile number (CurrentProfileNo) is not stored in Execution profile ID number (AxisName.Md.ProfileID) of the structuring axis in the axes group.

## ■Necessary object data

When using this FB, map the object assigned to the following object data for all structuring axes in the specified axes group to a PDO.

- Target position (607AH)

If a structuring axis that exists is the one without the object being mapped to PDO, Necessary object data unset (error code: 1AF7H) occurs and the operation will not start.

For details on object data settings, refer to the following manual.

📖 User's manual for the controller used

## Precautions

- In this FB, the start and multiple start (Aborting) operations may be delayed due to pre-reading and the operation profile data analysis on external signal settings and other items.

## Program example

This section provides examples of positioning control on Axes group 1 (AxesGroup001).

### • Operation

| Positioning data number | Path  | Positioning operation                                                                                                         |
|-------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------|
| 1                       | P0→P1 | Positioning with Absolute Value Linear Interpolation (LinearAbsolute) from the start point position (P0) to the position (P1) |
| 2                       | P1→P2 | Positioning with Absolute Value Circular Interpolation (CircularAbsolute) from the position (P1) to the position (P2)         |
| 3                       | P2→P3 | Positioning with Absolute Value Linear Interpolation (LinearAbsolute) from the position (P2) to the position (P3)             |
| 4                       | P3→P4 | Positioning with Relative Value Circular Interpolation (CircularRelative) from the position (P3) to the position (P4)         |
| 5                       | P4→P5 | Positioning with Relative Value Linear Interpolation (LinearRelative) from the position (P4) to the position (P5)             |
| 6                       | P5→P0 | Positioning with Absolute Value Linear Interpolation (LinearAbsolute) from the position (P5) to the end point position (P0)   |

### • Axes group

| Item                  | Setting value |
|-----------------------|---------------|
| Configuration axis[1] | Axis0001      |
| Configuration axis[2] | Axis0002      |

## ■Axis

| Axis No. | Label name | Data type | Comment |
|----------|------------|-----------|---------|
| 1        | Axis0001*1 | AXIS_REF  | Axis 1  |
| 2        | Axis0002*1 | AXIS_REF  | Axis 2  |

\*1 To perform circular interpolation control, set Software stroke limit target (AxisName.Pr.SwStrokeLimit\_Target) of an axis parameter to valid (a value other than "-1: Invalid (Invalid)"). (In the program example, "1: Set position (SetPosition)" is set.)

## ■Axes group

| Axes group No. | Label name   | Data type      | Comment      |
|----------------|--------------|----------------|--------------|
| 1              | AxesGroup001 | AXES_GROUP_REF | Axes group 1 |

## ■ Operation profile data

| Profile ID | Label name          | Data type               | Comment                          |
|------------|---------------------|-------------------------|----------------------------------|
| 1          | PositioningData0001 | MC_POSITIONING_DATA_REF | Multiple axes positioning data 1 |

### • Operation profile data (PositioningData0001 (Multiple axes positioning data)) settings

| Item                                                        |                         | Positioning data number                                  |                                             |                                        |                                             |                                                          |                                                      |

# 46.25 Absolute Position Tracking Control

46

## MCv\_PositionControl

This FB moves the specified axis to the target position according to the limit velocity, acceleration, deceleration, and jerk. In addition, even after the command has reached the target position, the axis can be moved by changing the target position with retrigger or continuous update.

Before using this FB, check the versions of the controller and engineering tool.

User's manual for the controller used

| Ladder diagram                                                                                                                                                                                                                                                                                                                                                                                                   | FBD/LD                                                                                                                                                                                                                                                                                                                                                       | ST                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Processing details

This FB moves the specified Axis (Axis) to Target position (Position) according to the limit velocity, Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). In addition, even after the command has reached the target position, the axis can be moved by changing Target position (Position) with retrigger or Continuous update (ContinuousUpdate).

When Target position (Position) is changed before the axis reaches Target position (Position), the axis moves to the target position after change.

Execution of this FB is completed when MC\_Stop (Forced Stop) or other motion FB is executed.

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

☞ Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Target position (Position)

The target position of the absolute position is set according to the axis unit. When the setting value is negative, the axis moves in the negative direction. When 0 is set, the axis does not move, but Axis status (AxisName.Md.AxisStatus) of the target axis becomes "5: During positioning operation (DiscreteMotion)".

The following table summarizes the valid ranges. If a value outside the range is set, Out of target position range (error code: 1A85H) occurs and the axis will not start.

| Ring counter setting | Valid range                                                                              |
|----------------------|------------------------------------------------------------------------------------------|
| Invalid              | $-10000000000.0 \leq \text{Target position} < 10000000000.0$                             |
| Valid                | Ring counter lower limit value $\leq$ Target position $<$ Ring counter upper limit value |

When the software stroke limit is valid (when Software stroke limit target (AxisName.Md.SwStrokeLimit\_Target) is set to a value other than "-1: Invalid (Invalid)")

- Software stroke limit over (target position) (error code: 1A80H) occurs and the axis will not start if a position which exceeds the software stroke limit is specified as the target position.
- The Direction selection (Direction) setting is ignored and positioning control is performed in a direction which does not cross over into the area outside the software stroke limit range.
- When the value does not cross over into the area outside the software stroke limit range both in the positive direction and the negative direction, positioning control is performed in the direction closest to Target position (Position) (the direction in which the absolute value of the movement amount is shortest) based on the current position.
- When the distance is the same between the positive direction and negative direction, the moving direction of the motion control FB executed the last time or the moving direction when the target position was changed in the previous execution will be carried over for the operation. If the previous moving direction is not available, the axis will move in the positive direction.

When the software stroke limit is invalid (when Software stroke limit target (AxisName.Md.SwStrokeLimit\_Target) is set to "-1: Invalid (Invalid)"), positioning control is performed within the valid range.

The target position change will be ignored one operation cycle before Target position reached (InAddress) becomes TRUE.

If Target position (Position) is changed, the changed operation varies depending on the Direction selection (Direction) setting.

- If a value outside the range is set for Target position (Position) during execution of the motion control FB, Out of Position/Distance setting range warning (event code: 00D0DH) occurs and the operation continues with the previous setting.
- When Out of Position/Distance setting range warning (event code: 00D0DH) occurs, if Direction selection (Direction) has been changed, the operation continues with the previous Direction selection (Direction) setting.
- When Out of direction selection range warning (event code: 00D4DH) occurs, the operation continues with the previous Target position (Position) setting.

### Ex.

When the shortest path is set, the axis moves from the set position at the time of the change in the direction closest to Target position (Position) after the change.

"Start" in the following refers to the start of the motion control FB after the first operation and the change of Target position (Position) after Target position reached (InAddress) becomes TRUE in the previous operation.

**Ex.**

When a path other than the shortest path is set, Target position (Position) is calculated from the set position and Direction selection (Direction) at the time of change.

"Start" in the following refers to the start of the motion control FB after the first operation and the change of Target position (Position) after Target position reached (InAddress) becomes TRUE in the previous operation.

If the reverse operation is performed due to the change in Target position (Position), or if the axis has passed Target position (Position) after the change during the change, the axis decelerates to stop. After the deceleration stop is completed, the operation starts toward the changed Target position (Position). In that case, no overrun error will occur.

AxisName.Md.SetVelocity

## ■Velocity (Velocity)

The command velocity is set for this FB.

### Setting range

0.0, 0.0001 to 2500000000.0

When the setting is omitted or set as 0.0, the axis does not operate, but Axis status (AxisName.Md.AxisStatus) changes to "6: During continuous operation (ContinuousMotion)".

If a value outside the range is set, Out of velocity range (error code: 1ABAH) occurs and the axis will not start.

For details on the operation while the motion control FB is being executed, refer to the user's manual for the controller used.

## ■Acceleration (Acceleration)

The acceleration is set for this FB. For details on the acceleration/deceleration method, refer to the user's manual for the controller used.

If a value outside the range is set, Out of acceleration range (error code: 1A8DH) occurs and the axis will not start.

For details on the operation while the motion control FB is being executed, refer to the user's manual for the controller used.

## ■Deceleration (Deceleration)

The deceleration is set for this FB. For details on the acceleration/deceleration method, refer to the user's manual for the controller used.

If a value outside the range is set, Out of deceleration range (error code: 1A8EH) occurs and the axis will not start.

For details on the operation while the motion control FB is being executed, refer to the user's manual for the controller used.

## ■Jerk (Jerk)

The jerk is set for this FB. For details on the acceleration/deceleration method, refer to the user's manual for the controller used.

If a value outside the range is set, Out of jerk range (error code: 1A8FH) occurs and the axis will not start.

## ■Direction selection (Direction)

The operation direction is specified. When continuous update or retrigger is performed, Direction selection (Direction) will not be reflected at the timing when the value is changed, but will be reflected when Target position (Position) is changed.

Choose one of the following:

- 1: Positive direction (mcPositiveDirection)
- 2: Negative direction (mcNegativeDirection)
- 3: Shortest path (mcShortestWay)

If a value outside the range is set for Direction selection (Direction) at start, Out of direction selection range (error code: 1AA5H) occurs and the axis will not start.

If a value outside the range is set for Direction selection (Direction) during control, Out of direction selection range warning (event code: 00D4DH) occurs and the operation continues with the previous setting. If Target position (Position) is changed at the same time as Direction selection (Direction), the operation continues with the previous Target position (Position) setting. The setting for Direction selection (Direction) is ignored when the software stroke limit is valid.

When the software stroke limit is invalid, the direction used to move from the current position to Target position (Position) can be set by selecting from "1: Positive direction (mcPositiveDirection)", "2: Negative direction (mcNegativeDirection)", or "3: Shortest path (mcShortestWay)" in Direction selection (Direction).

- 1: Positive direction (mcPositiveDirection)

Performs positioning from the current position to the target position in the positive direction (address increasing).

| Setting range                                                    | Operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Current value ≤ Target position < Ring counter upper limit value | <p>The graph shows a coordinate system with a vertical axis labeled 'Ring counter' and values -100.0, 0.0, and 100.0. The horizontal axis represents position. A dashed diagonal line represents the ring counter's periodic nature. A solid line shows the current value starting at 0.0 and moving upwards to a target position (marked with a circle) that is below the upper limit value of 100.0. An arrow indicates the direction of movement.</p>                                                                                           |
| Ring counter lower limit value ≤ Target position < Current value | <p>The graph shows a coordinate system with a vertical axis labeled 'Ring counter' and values -100.0, 0.0, and 100.0. The horizontal axis represents position. A dashed diagonal line represents the ring counter's periodic nature. A solid line shows the current value starting at 0.0 and moving upwards. It reaches the upper limit value of 100.0, wraps around to -100.0, and then continues to move upwards to a target position (marked with a circle) that is below the current value. An arrow indicates the direction of movement.</p> |

- 2: Negative direction (mcNegativeDirection)

Performs positioning in the negative direction (address decreasing) from the current position to the target position.

| Setting range                                                    | Operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ring counter lower limit value ≤ Target position ≤ Current value | <p>The graph shows a coordinate system with a vertical axis labeled 'Ring counter' and values -100.0, 0.0, and 100.0. The horizontal axis represents position. A dashed diagonal line represents the ring counter's periodic nature. A solid line shows the current value starting at 0.0 and moving downwards to a target position (marked with a circle) that is above the lower limit value of -100.0. An arrow indicates the direction of movement.</p>                                                                                            |
| Current value < Target position < Ring counter upper limit value | <p>The graph shows a coordinate system with a vertical axis labeled 'Ring counter' and values -100.0, 0.0, and 100.0. The horizontal axis represents position. A dashed diagonal line represents the ring counter's periodic nature. A solid line shows the current value starting at 0.0 and moving downwards. It reaches the lower limit value of -100.0, wraps around to 100.0, and then continues to move downwards to a target position (marked with a circle) that is above the current value. An arrow indicates the direction of movement.</p> |

- 3: Shortest path (mcShortestWay)

Based on the current position, positioning control is performed in the direction closest to the target position (the direction in which the absolute value of the movement amount is shortest). If the distance is the same in both the positive direction and the negative direction, control is performed using the current direction. The setting range of the target position is "Ring counter lower limit value  $\leq$  Target position  $<$  Ring counter upper limit value". If a value outside the range is set, Out of target position range (error code: 1A85H) occurs and the axis will not start.

**Ex.**

Operation when set to the values shown below

- Ring counter upper limit value: 100.0
- Ring counter lower limit value: -100.0
- Current position: 80.0
- Target position: -80.0

Since the movement amount of (1) is "160.0" and the movement amount of (2) is "40.0", positioning moves in the positive direction from (2).

## ■ Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following table shows the buffer modes that can be set for this FB.

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Aborting (mcAborting)                 | Aborts (cancels) the under-control FB and executes the next FB immediately.                                                                                                                                                                                                                                                                                                                                                                          |
| 1: Buffered (mcBuffered)                 | Buffers the next FB on the under-control FB.<br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after completion of the under-control FB.                                                                                                                                                                                                    |
| 2: BlendingLow (mcBlendingLow)           | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the lower target velocity between the under-control FB and the buffering FB is used as the switching speed.  |
| 3: BlendingPrevious (mcBlendingPrevious) | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the under-control FB is used as the switching speed.                                  |
| 4: BlendingNext (mcBlendingNext)         | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the target velocity of the buffering FB is used as the switching speed.                                      |
| 5: BlendingHigh (mcBlendingHigh)         | Buffers the next FB on the under-control FB.* <sup>1</sup><br>If the under-control FB already has an FB buffering on it, subsequent FBs are buffered consecutively. (Up to 2.)<br>Buffering FBs are executed in order after the under-control FB reaches the target position.<br>When the under-control FB reaches the target position, the higher target velocity between the under-control FB and the buffering FB is used as the switching speed. |

\*<sup>1</sup> Stops are not performed between the under-control FB and the buffering FB.

For details on multiple start (buffer mode), refer to the following.

User's manual for the controller used

## ■Options (Options)

The function options for this FB are set in the specified bit position.

The following figure shows how the settings should be configured with bit specification.

\*1 Set empty areas to "0". If a value other than "0" is set, Out of Options Range (error code: 1ABBH) occurs.

| Bit    | Name                                     | Description                                                                                                                                                                                                                                                 |
|--------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 1 | Acceleration/deceleration method setting | Sets the acceleration/deceleration method used to perform control. <ul style="list-style-type: none"> <li>• 0: Acceleration/deceleration specification method (mcAccDec)</li> <li>• 1: Acceleration/deceleration time-fixed method (mcFixedTime)</li> </ul> |

### • Acceleration/deceleration method setting (bit 0 to 1)

| Setting value                                                | Description                                                                                                                                                                                                                                        |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Acceleration/deceleration specification method (mcAccDec) | An acceleration/deceleration method using Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk) set in this FB                                                                                                                 |
| 1: Acceleration/deceleration time-fixed method (mcFixedTime) | An acceleration/deceleration method using the acceleration/deceleration time set in this FB regardless of the velocity. The acceleration/deceleration time does not use Acceleration (Acceleration), Deceleration (Deceleration), and Jerk (Jerk). |

## Precautions

If Target position (Position) and Direction selection (Direction) are changed at the same time, data inconsistency may occur. By changing Direction selection (Direction) before changing Target position (Position), both changes can be applied when Target position (Position) is changed. If the values of Target position (Position) and Direction selection (Direction) need to be changed at the same time, execute this FB with the program execution cycle set to "Fixed Scan" or restart this FB.

## Program example

The following is a program example that uses this FB to move the workpiece on the XYθ table to the reference position based on the correction information (θ/X/Y axis correction values) from the sensor.

- Operation

- (1): XYθ table  
 (2): Reference position  
 (3): Sensor  
 (4): Workpiece  
 (5): The position is corrected by following the position based on the correction information from the sensor.

### ■Axes

| Setting item          | X axis          | Y axis          | θ axis          |
|-----------------------|-----------------|-----------------|-----------------|
| Axis type             | Real drive axis | Real drive axis | Real drive axis |
| Position command unit | μm              | μm              | degree          |

### ■Labels used

| Label name                   | Data type                    | Comment                                                                       |
|------------------------------|------------------------------|-------------------------------------------------------------------------------|
| bMCv_PositionControl_Execute | Bit                          | Control start                                                                 |
| leMCv_PositionControl_Pos_1  | Double-precision real number | Input to MCv_PositionControl_1.Position                                       |
| leMCv_PositionControl_Pos_2  | Double-precision real number | Input to MCv_PositionControl_2.Position                                       |
| leMCv_PositionControl_Pos_3  | Double-precision real number | Input to MCv_PositionControl_3.Position                                       |
| leCorrectionValue_Theta      | Double-precision real number | θ-axis correction value (input the correction value obtained from the sensor) |
| leCorrectionValue_XPos       | Double-precision real number | X-axis correction value (input the correction value obtained from the sensor) |
| leCorrectionValue_YPos       | Double-precision real number | Y-axis correction value (input the correction value obtained from the sensor) |

## ■ST program

```
//Input the correction value from the sensor
leMCv_PositionControl_Pos_1:= leCorrectionValue_Theta;
leMCv_PositionControl_Pos_2:= leCorrectionValue_XPos;
leMCv_PositionControl_Pos_3:= leCorrectionValue_YPos;
```

```
//-----Axis 1: Absolute position follow-up control-----
```

```
MCv_PositionControl_1 (
  Axis:= Axis0001.AxisRef ,

  Position:= leMCv_PositionControl_Pos_3
  Velocity:= 10000000.0 ,
  Acceleration:= 100000.0 ,
  Deceleration:= 100000.0 ,
  Jerk:= 0.0 ,
  Direction:= MC_DIRECTION__mcPositiveDirection ,
  BufferMode:= MC_BUFFER_MODE__mcAborting ,
  Options:= 0
);
```

# 46.26 Motion Cyclic Position Control

## MCv\_CyclicPosition

This FB sends the target position to a drive unit according to the specified target position.

### Restriction

Before using this FB, check the versions of the controller and engineering tool.

 User's manual for the controller used

## Processing details

The control mode on the drive unit side is switched to csp (cyclic synchronous position mode), and the command position is sent. To stop this FB, use MC\_Stop (Forced Stop).

### ■ Timing chart

- When the processing is completed successfully

- When I/O variables are abnormal

- When an input variable is abnormal

## ■Target position (Position)

The target position of the absolute position is set in the positioning range. The following table summarizes the valid ranges. If a value outside the range is set, Out of target position range (error code: 1A85H) occurs.

| Ring counter setting | Valid range                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------|
| Invalid              | $-10000000000.0 \leq \text{Target position} < 10000000000.0$                                                |
| Valid                | $\text{Ring counter lower limit value} \leq \text{Target position} < \text{Ring counter upper limit value}$ |

When the software stroke limit is valid (when Software stroke limit target (AxisName.Md.SwStrokeLimit\_Target) is set to a value other than "-1: Invalid (Invalid)"), positioning control is performed in a direction which does not cross over into the area outside the software stroke limit range. When the value does not cross over into the area outside the software stroke limit range both in the positive direction and the negative direction, positioning control is performed in the direction closest to the target position (the direction in which the absolute value of the movement amount is shortest) based on the current position. When the distance is the same between the positive direction and negative direction, the moving direction of the motion control FB executed previously or the moving direction at the previous target position change will be carried over for the operation. In addition, even when the value set is within the valid range, Software stroke limit over (target position) (error code: 1A80H) occurs if a position which exceeds the software stroke limit is specified as the target position.

When the software stroke limit is invalid (when Software stroke limit target (AxisName.Md.SwStrokeLimit\_Target) is set to "-1: Invalid (Invalid)"), refer to the following.

☞ Page 1937 Direction selection (Direction)

When changing Target position (Position), change it within the following range. If the setting is configured so that the value after the electronic gear conversion exceeds 31 bits, Out of the movement amount range after driver position unit conversion (error code: 1B3CH) occurs.

Change amount of target position  $\times$  Driver unit conversion numerator/Driver unit conversion denominator  $\leq 2000000000$

### Ex.

An example of calculating the target position under the following conditions is shown below.

| Item                     | Value                  |
|--------------------------|------------------------|
| Motor encoder resolution | 67108864 [pulse/rev]   |
| Worm gear pitch          | 1000 [ $\mu\text{m}$ ] |
| External gear ratio      | 1/10                   |

When the electronic gear settings specify the number of pulses per servo motor rotation as 67108864 [pulse] and the movement amount per servo motor rotation as 100.0 [ $\mu\text{m}$ ], the change amount of the target position is within or falls below the following range.

$$\begin{array}{l} \text{Target position} \\ \text{variation amount} \end{array} = 2000000000 \div \frac{\text{Driver unit conversion} \\ \text{numerator}}{\text{Driver unit conversion} \\ \text{denominator}} = 2000000000 \div \frac{\text{Number of pulses per} \\ \text{rotation}}{\text{Movement amount per} \\ \text{rotation}} = 2000000000 \div \frac{67108864}{100.0} = 2980.23\dots$$

## ■Direction selection (Direction)

When the software stroke limit is disabled, the direction used to move from the current position to the target position is specified.

The setting range can be selected from "1: Positive direction (mcPositiveDirection)", "2: Negative direction (mcNegativeDirection)", and "3: Shortest path (mcShortestWay)".

The setting for Direction selection (Direction) is ignored when the software stroke limit is valid.

If a value outside the range is set for Direction selection (Direction) at start, Out of direction selection range (error code: 1AA5H) occurs and the axis will not start.

If a value outside the range is set for Direction selection (Direction) during control, Out of direction selection range warning (event code: 00D4DH) occurs and the operation continues with the previous setting. Also, if Target position (Position) is changed at the same time as Direction selection (Direction), the operation continues with the previous Target position (Position) setting.

For the moving direction according to Direction selection (Direction), the operation at the start of the motion control FB is based on the set position at the start, and the operation after the start of the motion control FB is based on the set position at the target position change.

- 1: Positive direction (mcPositiveDirection)

Performs positioning from the current position to the target position in the positive direction (address increasing).

| Setting range                                                         | Operation                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Current value $\leq$ Target position < Ring counter upper limit value | <p>The graph shows a sawtooth wave for the Ring counter. The y-axis ranges from -100.0 to 100.0, with 0.0 in the middle. The x-axis represents position. A solid line with an arrow points from the current value (0.0) to the target position (also 0.0), indicating no movement. The Ring counter upper limit value is at 100.0 and the lower limit value is at -100.0.</p>                            |
| Ring counter lower limit value $\leq$ Target position < Current value | <p>The graph shows two sawtooth waves. The top graph, labeled AxisName.Md.FeedMachinePosition, has a y-axis from -200 to 200. The bottom graph, labeled AxisName.Md.SetPosition, has a y-axis from -100 to 100. In both, the current value is 0.0. The target position is 200, which is beyond the upper limit of 100. The movement is shown as a solid line with an arrow pointing from 0.0 to 200.</p> |

- 2: Negative direction (mcNegativeDirection)

Performs positioning in the negative direction (address decreasing) from the current position to the target position.

| Setting range                                                              | Operation                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ring counter lower limit value $\leq$ Target position $\leq$ Current value | <p>The graph shows a sawtooth wave for the Ring counter. The y-axis ranges from -100.0 to 100.0, with 0.0 in the middle. The x-axis represents position. A solid line with an arrow points from the current value (0.0) to the target position (also 0.0), indicating no movement. The Ring counter upper limit value is at 100.0 and the lower limit value is at -100.0.</p>                             |
| Current value < Target position < Ring counter upper limit value           | <p>The graph shows two sawtooth waves. The top graph, labeled AxisName.Md.FeedMachinePosition, has a y-axis from -200 to 0. The bottom graph, labeled AxisName.Md.SetPosition, has a y-axis from -100 to 100. In both, the current value is 0.0. The target position is -200, which is beyond the lower limit of -100. The movement is shown as a solid line with an arrow pointing from 0.0 to -200.</p> |

- 3: Shortest path (mcShortestWay)

Based on the current position, positioning control is performed in the direction closest to the target position (the direction in which the absolute value of the movement amount is shortest). If the distance is the same in both the positive direction and the negative direction, control is performed using the current direction. The setting range of the target position is "Ring counter lower limit value  $\leq$  Target position  $<$  Ring counter upper limit value". If a value outside the range is set, Out of target position range (error code: 1A85H) occurs and the axis will not start.

**Ex.**

Operation when set to the values shown below

- Ring counter upper limit value: 100.0
- Ring counter lower limit value: -100.0
- Current position: 80.0
- Target position: -80.0

Since the movement amount of (1) is "160.0" and the movement amount of (2) is "40.0", positioning moves in the positive direction from (2).

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following table shows the buffer modes that can be set for this FB.

| Setting value            | Description                                                                 |
|--------------------------|-----------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately. |

### Point

For details on multiple start (buffer mode), refer to the following.

 User's manual for the controller used

## Precautions

- The motion cyclic position control does not configure the settings for acceleration, deceleration, and jerk, which may result in sudden acceleration or deceleration when sending the command position. Therefore, set the following speed limit values with safety considerations: Positive Direction Speed Limit Value (AxisName.Pr.VelocityLimit\_Positive) for the positive direction and Negative Direction Speed Limit Value (AxisName.Pr.VelocityLimit\_Negative) for the negative direction.
- If the set velocity exceeds the speed limit value for each axis, the operation follows Operation Setting at Velocity Limit Value Exceeded (AxisName.Pr.VelocityLimit\_OverOperation). Also, if the absolute value of the set velocity exceeds the maximum velocity, Velocity range over during controlling (error code: 1B1AH) occurs and the operation stops.
- To switch from a control mode other than csp to csp using multiple starts of MCv\_CyclicPosition (Motion Cyclic Position Control), ensure that the motor has stopped before switching. If not, the difference between the current position and MCv\_CyclicPosition (Motion Cyclic Position Control) becomes large, and the sudden operation may occur.

## Program example

For a program example of this FB, refer to the following manual.

 User's manual for the controller used

# 46.27 Motion Cyclic Velocity Control

46

## MCv\_CyclicVelocity

This FB sends the target velocity to a drive unit according to the specified target velocity.

### Restriction

Before using this FB, check the versions of the controller and engineering tool.

 User's manual for the controller used

| ErrorID         | Error code              | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

The control mode on the drive unit side is switched to csv (cyclic synchronous velocity mode), and the command velocity is sent. To stop this FB, use MC\_Stop (Forced Stop).

### ■Timing chart

- When the processing is completed successfully

- When I/O variables are abnormal

- When an input variable is abnormal

### ■Target velocity (Velocity)

The target velocity is set. If a value outside the range is set at the start, Out of velocity range (error code: 1ABAH) occurs. If a value outside the range is set during control, Out of velocity range warning (event code: 00D0FH) occurs.

Set the value so that the command velocity after driver velocity unit conversion falls within the range from -2147483648 to 2147483647. If the command velocity after conversion is outside the range, Set velocity of converted driver velocity unit out of range (error code: 1A90H) occurs regardless of the operation status.

The command velocity after driver velocity unit conversion is determined by the following equation:

Command velocity after driver velocity unit conversion = Velocity command unit × (Driver unit conversion numerator ÷ Driver unit conversion denominator)

When the velocity is set to a negative value, the axis moves in the negative direction.

When 0 is set at the start, the axis does not operate, but Axis status (AxisName.Md.AxisStatus) of the target axis changes to "6: During continuous operation (ContinuousMotion)".

When this FB is started multiple times and Target velocity (Velocity) is set to 0, the axis operates at the command velocity of the previous motion control FB.

### ■Direction selection (Direction)

The direction used to move from the current position to the target position is specified.

The setting range can be selected from "1: Positive direction (mcPositiveDirection)", "2: Negative direction (mcNegativeDirection)", and "3: Shortest path (mcShortestWay)". When "2: Negative direction (mcNegativeDirection)" is set and Target velocity (Velocity) is set to a negative value, the movement direction of the motor will be positive.

If a value outside the range is set for Direction selection (Direction) at start, Out of direction selection range (error code: 1AA5H) occurs and the axis will not start.

### ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following table shows the buffer modes that can be set for this FB.

| Setting value            | Description                                                                 |
|--------------------------|-----------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately. |

#### Point

For details on multiple start (buffer mode), refer to the following.

 User's manual for the controller used

### Precautions

When setting the target velocity, set the value so that the difference between the current velocity and the target velocity is not too large. If the difference is too large, the axis may suddenly accelerate.

When a stop cause occurs while this FB is starting, the axis will stop immediately.

### Program example

For a program example of this FB, refer to the following.

 User's manual for the controller used

# 46.28 Motion Cyclic Torque Control

## MCv\_CyclicTorque

The target torque is sent to the drive unit according to the specified target torque.

Before using this FB, check the versions of the controller and engineering tool.

Set 0. If a value other than 0 is set, Out of options range (error code: 1ABBH) occurs.          |

## ■ Output variables

| Output variable | Name                  | Data type  | Default value | Description                                                                                                                                                                                                                                     |
|-----------------|-----------------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| InTorque        | Target torque reached | BOOL       | FALSE         | This variable becomes TRUE when Cst_SetTorque sent from a drive unit reaches the target torque. This variable becomes FALSE after the axis stops due to error or stop cause occurrence.                                                         |
| Busy            | Executing             | BOOL       | FALSE         | This variable becomes TRUE when this FB is operating.                                                                                                                                                                                           |
| Active          | Controlling           | BOOL       | FALSE         | This variable becomes TRUE when this FB is controlling the axis.                                                                                                                                                                                |
| CommandAborted  | Abortion of execution | BOOL       | FALSE         | This variable becomes TRUE when execution is aborted by another FB.                                                                                                                                                                             |
| Error           | Error                 | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                |
| ErrorID         | Error code            | WORD(UINT) | 0             | When an error occurs, this variable returns the error code.<br>For details on error codes, refer to the following.<br> User's manual for the controller used |

## Processing details

The control mode on the drive unit side is switched to cst (cyclic synchronous torque mode), and the command velocity is sent. To stop this FB, use MC\_Stop (Forced Stop).

### ■Timing chart

- When the processing is completed successfully

- When I/O variables are abnormal

- When an input variable is abnormal

## ■Target torque (Torque)

The ratio of the servo motor used to the rated torque is set in percentage.

If a value outside the range is set at the start, Out of target torque range (error code: 1A96H) occurs.

If a value outside the range is set during control, Out of torque setting range warning (event code: 00D16H) occurs.

The number of significant digits for the target torque varies depending on the specifications for Target Torque of the connected drive unit. If the value set for the target torque contains a value equal to or less than the number of significant digits of Target Torque, it is rounded down.

To output the command torque in the positive direction (address increasing direction), set a positive value. To output the command torque in the negative direction (address decreasing direction), set a negative value.

To reverse the target torque direction for safety reasons, set the target torque to 0 once.

### Ex.

To change the target torque from -10.0 to 10.0, change the value in the following order.

-10.0 → 0.0 → 10.0

## ■Limit velocity (LimitVelocity)

The velocity limit value for the cyclic synchronous torque mode is set in the range from -2500000000.0 to 2500000000.0. If a value outside the range is set, Out of limit velocity range (error code: 1A86H) occurs at start, and Out of limit velocity range warning (event code: 00D1BH) occurs during control.

Set the value so that the command velocity after driver velocity unit conversion does not go out of the range from -2147483648 to 2147483647 [0.01rpm]. If a value outside the range is set, Set velocity of converted driver velocity unit out of range (error code: 1A90H) occurs.

The command velocity after driver velocity unit conversion is determined by the following equation:

Command velocity after driver velocity unit conversion = Velocity command unit × (Driver unit conversion numerator ÷ Driver unit conversion denominator)

When 0 is set at the start, the axis does not operate, but Axis status (AxisName.Md.AxisStatus) of the target axis changes to "6: During continuous operation (ContinuousMotion)".

When MC\_CyclicTorque (torque control) is executed by multiple start and 0 is stored in LimitVelocity (LimitVelocity), the motor speed of the previous motion control FB is controlled as Limit velocity (LimitVelocity).

Limit velocity (LimitVelocity) becomes valid when the following conditions are met.

- An object corresponding to Limit velocity (LimitVelocity) during cyclic synchronous torque mode (cst) for the connected drive unit is mapped and assigned to a PDO.
- The mapped object data is set to vVelLimitValue (AxisName.PrConst.SlaveObject.vVelLimitValue).

The setting method for enabling the velocity limit with Limit velocity (LimitVelocity) varies depending on the drive unit.

- When using the MR-J5(W)-G, map and assign Velocity limit value to a PDO.
- When using a drive unit other than the MR-J5(W)-G, map and assign an object corresponding to the limit velocity during cyclic synchronous torque mode (cst) for the connected drive unit to a PDO. Then, set the mapped object data to vVelLimitValue (AxisName.PrConst.SlaveObject.vVelLimitValue).

When the velocity limit in Limit velocity (LimitVelocity) is invalid, the velocity limit of the controller cannot be valid.

- When using the MR-J5(W)-G, use an engineering tool to set the setting value of the servo parameter [Pr.PT67 Speed limit].
- When using a drive unit other than the MR-J5(W)-G, use the velocity limit function of the connected drive unit. For details, refer to the user's manual for the connected drive unit.

## ■Buffer mode (BufferMode)

Sets the operation used to perform multiple start (buffer mode).

The following table shows the buffer modes that can be set for this FB.

| Setting value            | Description                                                                 |
|--------------------------|-----------------------------------------------------------------------------|
| 0: Aborting (mcAborting) | Aborts (cancels) the under-control FB and executes the next FB immediately. |

### Point

For details on multiple start (buffer mode), refer to the following.

 User's manual for the controller used

## Precautions

- The set position and the feed machine position are updated by follow up.
- The switching time of the control mode by this FB varies depending on the specifications for the drive unit used.
- When a stop cause occurs while this FB is starting, the axis will stop immediately.
- Do not start a positioning control FB while this FB is operating. Check that Driver control mode (AxisName.Md.Driver\_Mode) has switched to "10: Torque control (cst)" before starting the positioning control FB.
- If the torque set as the target torque is insufficient, the torque may suddenly drop depending on the mechanism or load. When setting a small value for the target torque, take sufficient care for safety.
- When the axis stops, store the value in Limit velocity (LimitVelocity) after checking that the control mode is switched. If the value is already stored in Limit velocity (LimitVelocity) before the mode is switched, the velocity may suddenly increase, creating a dangerous situation.
- Limit velocity (LimitVelocity) is recommended during cst. When Limit velocity (LimitVelocity) is not used, a large difference between the current torque and the target torque may cause the velocity to suddenly increase, depending on the mechanism and load application, creating a dangerous situation.
- For the torque limit change during cst, pay attention to the operations when the following changes are made.

| Change content                                                                                                                                                                                                                                                                         | Operation                                                                                                                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| At restart or continuous update, the target torque was changed to a value bigger than the torque limit value (Positive direction torque limit value ( <u>AxisName.Md.TorqueLimit_Positive</u> ) or Negative direction torque limit value ( <u>AxisName.Md.TorqueLimit_Negative</u> )). | Torque limit value over warning (event code: 00D12H) occurs, and the operation is performed with the value before the change. |
| During torque control, Positive direction torque limit value ( <u>AxisName.Cd.TorqueLimit_Positive</u> ) or Negative direction torque limit value ( <u>AxisName.Cd.TorqueLimit_Negative</u> ) was changed to a value smaller than the target torque.                                   | The target torque is changed to the torque limit value. In this case, the command torque is changed in one operation cycle.   |

- While this FB is operating, the continuous operation to torque control mode cannot be switched by multiple starts of MC\_TorqueControl (Torque control). When the control mode is switched, Control mode switching disabled warning (event code: 00D31H) occurs and the operation is performed in the current control mode.
- This FB cannot be executed during the continuous operation to torque control. If the control mode is switched, Control mode switching error (error code: 1A95H) occurs.
- When the control mode is switched from cst using multiple starts of MCv\_CyclicTorque (Motion Cyclic Torque Control), the command torque set in MCv\_CyclicTorque (Motion Cyclic Torque Control) is immediately sent. Set a value so that the difference between the command torque and speed limit before and after multiple starts does not become large. If the difference is large, the sudden operation may occur.

## Program example

For a program example of this FB, refer to the following.

 User's manual for the controller used

## 47.1 Profile Read

### MCv\_ReadProfileData

This FB reads the specified operation profile data from the open area or a file.

| Ladder | FBD/LD | ST                                                                                                                                                                                                                                                                                               |

## Processing details

- This FB reads the operation profile data.
- The file specified in Profile data (ProfileData) and Read destination (Target), or the operation profile data in the open area are read for the number of points specified in Number of read data (Points) from the data specified with Offset (Offset).
- To read the whole operation profile data, specify "0" in both Offset (Offset) and Number of read data (Points).
- Read data is stored in variables specified in Read data 1 (Data1) and Read data 2 (Data2).

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

👉 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Offset (Offset) and Number of read data (Points) setting

The following operations are based on the values set in Offset (Offset) and Number of read data (Points).

| Offset (Offset) | Number of read data (Points) | Size relationship with the number of elements of the operation profile data                                                 | Operation                                                                                                           |
|-----------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| 0               | 0                            | —                                                                                                                           | Reads all operation profile data elements.                                                                          |
|                 | Other than 0                 | $\text{Offset (Offset)} + \text{Number of read data (Points)} \leq \text{number of elements of the operation profile data}$ | Reads the number of operation profile data elements set in Number of read data (Points) from the top.               |
|                 | Other than 0                 | $\text{Offset (Offset)} + \text{Number of read data (Points)} > \text{number of elements of the operation profile data}$    | Reads all operation profile data elements.                                                                          |
| Other than 0    | 0                            | $\text{Offset (Offset)} \leq \text{number of elements of the operation profile data}$                                       | Number of Offset/Read/Write Data Incorrect (error code: 1BADH) occurs, and read is not executed.                    |
|                 | Other than 0                 | $\text{Offset (Offset)} + \text{Number of read data (Points)} \leq \text{number of elements of the operation profile data}$ | Reads the number of operation profile data elements specified in Number of read data (Points) from Offset (Offset). |
|                 | Other than 0                 | $\text{Offset (Offset)} + \text{Number of read data (Points)} > \text{number of elements of the operation profile data}$    | Reads until the final element of the operation profile data from Offset (Offset).                                   |
|                 | —                            | $\text{Offset (Offset)} > \text{number of elements of the operation profile data}$                                          | Out of Offset Range (error code: 1B92H) occurs, and read is not executed.                                           |

The contents of the values set for Offset (Offset) and Number of read data (Points) vary depending on the operation profile data format.

The following describes the contents when "cam data" and "rotary cutter" are set to the operation profile data format.

- When the operation profile data format is "cam data"

| Specifying interpolation method (Interpolate) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                               |               |               |     |                              |                               |     |                              |                               |     |                              |                               |     |              |              |     |              |              |     |              |              |     |              |              |     |              |              |  |                              |                               |  |                              |                               |  |                              |                               |  |                              |                               |  |                              |                               |  |                              |                               |  |                              |                               |  |                              |                               |

The data stored in Read data 1 (Data1) is the PROFILE_CAM_DATA type data when Specifying interpolation method (Interpolate) is "0: Linear interpolation" and the operation profile data format is "cam data". The data stored in Read data 2 (Data2) is data defined by using target cam data divided equally by the cam resolution points (a pair of current value per cycle and stroke) which is defined in LREAL type two-dimensional array.</p> <p>&lt;Example&gt;<br/>Read result of Read data 2 (Data2) when Offset (Offset) is set to "2" and Number of read data (Points) is set to "3".<br/>(When the variable set to Read data 2 (Data2) is a "LREAL[1..8,1..2]" data type "CamData2" label.)</p> <div><div><p>&lt;Variable (label/device)&gt;<br/>Two-dimensional array label of LREAL type<br/>(CamData2[1..8,1..2])</p><table><thead><tr><th></th><th>CamData[n][1]</th><th>CamData[n][2]</th></tr></thead><tbody><tr><td>n=1</td><td>Current value per cycle at the 2nd point</td><td>Stroke at the 2nd point</td></tr><tr><td>n=2</td><td>Current value per cycle at the 3rd point</td><td>Stroke at the 3rd point</td></tr><tr><td>n=3</td><td>Current value per cycle at the 4th point</td><td>Stroke at the 4th point</td></tr><tr><td>n=4</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=5</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=6</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=7</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=8</td><td>Not updating</td><td>Not updating</td></tr></tbody></table></div><div><p>Start point                      Initial stroke<br/>&lt;Open area&gt;</p><table><thead><tr><th>0</th><th>0</th></tr></thead><tbody><tr><td>Current value per cycle at the 1st point</td><td>Stroke at the 1st point</td></tr><tr><td>Current value per cycle at the 2nd point</td><td>Stroke at the 2nd point</td></tr><tr><td>Current value per cycle at the 3rd point</td><td>Stroke at the 3rd point</td></tr><tr><td>Current value per cycle at the 4th point</td><td>Stroke at the 4th point</td></tr><tr><td>Current value per cycle at the 5th point</td><td>Stroke at the 5th point</td></tr><tr><td>⋮</td><td>⋮</td></tr><tr><td>Current value per cycle at the 255th point</td><td>Stroke at the 255th point</td></tr></tbody></table><p>↑<br/>Data in which cam data is divided equally by the number of points of cam resolution</p></div><div><p>Offset</p><p>Number of read data (Points)</p></div></div> |                         | CamData[n][1] | CamData[n][2] | n=1 | Current value per cycle at the 2nd point | Stroke at the 2nd point | n=2 | Current value per cycle at the 3rd point | Stroke at the 3rd point | n=3 | Current value per cycle at the 4th point | Stroke at the 4th point | n=4 | Not updating | Not updating | n=5 | Not updating | Not updating | n=6 | Not updating | Not updating | n=7 | Not updating | Not updating | n=8 | Not updating | Not updating | 0 | 0 | Current value per cycle at the 1st point | Stroke at the 1st point | Current value per cycle at the 2nd point | Stroke at the 2nd point | Current value per cycle at the 3rd point | Stroke at the 3rd point | Current value per cycle at the 4th point | Stroke at the 4th point | Current value per cycle at the 5th point | Stroke at the 5th point | ⋮ | ⋮ | Current value per cycle at the 255th point | Stroke at the 255th point |

## ■Read data 1 (Data1)/Read data 2 (Data2)

Set read data of the operation profile data with a TARGET\_REF structure. The [VAR] and [DEV] data types can be used. For details on the TARGET\_REF structure, refer to the following.

📖 Page 1489 TARGET\_REF (Input signal)

For data types, read data structures of each operation profile data format can be used.

- Read data 1 (Data1) The operation profile data formats and data types set in Read data 1 (Data1) are shown below.

| Operation profile data format | Data type             | Reference                       |
|-------------------------------|-----------------------|---------------------------------|
| Cam data                      | PROFILE_CAM_DATA      | Page 1494 PROFILE_CAM_DATA      |
| Cam data for rotary cutter    | PROFILE_ROTARY_CUTTER | Page 1496 PROFILE_ROTARY_CUTTER |

### Ex.

When reading by using a device or label

- When reading a PROFILE\_CAM\_DATA type label (CamData1)

Data1.Target := "[VAR]CamData1"

- Read data 2 (Data2) The operation profile data formats and data types set in Read data 2 (Data2) are shown below. The data type of the structure that is set varies depending on Read destination (Target) and Specifying interpolation method (Interpolate) of the target cam data.

If the number of elements of the specified array is less than (the resolution + 1/number of coordinates) when the entire operation profile data is read, Number of Read/Write Data Mismatch (error code: 1BACH) occurs.

○: Supported, ×: Not supported

- \*1 The LREAL type two-dimensional array is set as follows.

LREAL[m..n,o..p]

| Item                         | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of elements (n-m+1)   | Sets the array elements so that they are greater than the number of points that are to be read.<br>When reading the entire operation profile data (Offset (Offset), Number of read data (Points) are set to "0"), set this to the cam data resolution + 1/the number of coordinates or more.<br>However, an area bigger than the resolution + 1/number of coordinates in Read data 1 (Data1) will not be updated. |
| Number of dimensions (p-o+1) | The stroke and current position per cycle for each point are read.<br>Set the array element to "2".<br>If the array element is set to "3" or more, a read is possible, but as the intended result of the read may not be obtained due to data being moved forward, make sure to set the array element to "2".                                                                                                     |

- \*2 The PROFILE\_CAM\_ELEMENT array is set as follows.

PROFILE\_CAM\_ELEMENT[m..n]

| Item                       | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of elements (n-m+1) | Sets the array elements so that they are greater than the number of points that are to be read.<br>When reading the entire operation profile data (Offset (Offset), Number of read data (Points) are set to "0"), set this to the cam data Number of sections (NumberOfSections) or more.<br>However, an area bigger than the Number of sections (NumberOfSections) in Read data 1 (Data1) will not be updated. |

- \*3 Reads as stroke data (a pair of current value per cycle and stroke) opened to the open area. X of 1st point data is the value set in start point, and Y of 1st point data is the value set in initial stroke amount.

Data after the 2nd point is stroke data divided by the resolution. Due to this, the read points in the open area is "resolution+1".

- \*4 Only used by the end point and stroke.

**Ex.**

When setting LREAL type with Specifying interpolation method (Interpolate)

| Specifying interpolation method (Interpolate) | Setting example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <p>The following shows examples of setting the two-dimensional label number of sections "10" to Target (Target) of the TARGET_REF structure.</p> <p>Data2.Target := "[VAR]CamData2"</p> <ul style="list-style-type: none"> <li>* CamData2 declares the "PROFILE_CAM_ELEMENT[1..10]" label to data type and label name of the global label to "CamData2", and specifies the character string for Target (Target). The read data is as shown below. <ul style="list-style-type: none"> <li>· CamData2[n]: nth point section data (PROFILE_CAM_ELEMENT type)</li> </ul> </li> </ul> |

**Point** 

- If the type of the specified data structure for reading does not match the type that is required for each operation profile data, Read/Write Data Type Incorrect (error code: 1BAAH) occurs.
- For details on the cam data for the operation profile data set in Read data 1 (Data1)/Read data 2 (Data2), refer to the following.

 User's manual for the controller used

## ■Read destination (Target)

Sets the read destination of the operation profile data.

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Open area                             | <ul style="list-style-type: none"><li>• The Profile ID (ID) value of the PROFILE_DATA structure is referred to, and the read is performed for the operation profile data that Profile ID No. (Number) of the PROFILE_ID structure indicates in the open area.</li><li>• The read is performed at the cycle of the executed program.</li><li>• If the operation profile data does not exist (unopened), No Operation Profile Data (error code: 1B8EH) occurs.</li></ul>       |
| 1: File                                  | <ul style="list-style-type: none"><li>• The Operation profile data storage location (Location) value of the PROFILE_DATA structure is referred, and the read is performed for the operation profile data that the file name and the path indicate.</li><li>• The read is performed at the cycle of the motion service processing.</li><li>• If the operation profile data does not exist, No Operation Profile Data (error code: 1B8EH) occurs.</li></ul>                    |
| 2: Open area (motion service processing) | <ul style="list-style-type: none"><li>• The Profile ID (ID) value of the PROFILE_DATA structure is referred, and the read is performed for the operation profile data that Profile ID No. (Number) of the PROFILE_ID structure indicates in the open area.</li><li>• The read is performed at the cycle of the motion service processing.</li><li>• If the operation profile data does not exist (unopened), No Operation Profile Data (error code: 1B8EH) occurs.</li></ul> |

### Point

- When Read destination (Target) is "1: File" or "2: Open area (motion service processing)", as motion service processing is used in that case, it may take much time for the processing to complete. Use Done (Execution completion) for the interlock as needed.
- When Target is set to "0: Open area", the processing is completed immediately as it is performed within the task where the FB is called. The program execution time increases when the number of write data points is too large. Therefore, execute the write multiple times with smaller data quantities as needed, or use the setting with Target set to "2: Open area (motion service processing)".

## Precautions

The number of data points that can be read at the same time are limited. If the read is not completed in a single FB execution, execute the read over several FB executions.

## Program example

The following is a program example. "LREAL type (two-dimensional array) format" cam data 1 (ProfileData0001) and "PROFILE\_CAM\_ELEMENT format" cam data 2 (ProfileData0002) are read from the file.

### ■ Operation profile data

| Profile ID | Label name      | Data type  | Comment    |
|------------|-----------------|------------|------------|
| 1          | ProfileData0001 | MC_CAM_REF | Cam data 1 |
| 2          | ProfileData0002 | MC_CAM_REF | Cam data 2 |

## ■Output variables

| Output variable | Name       | Data type  | Default value | Description                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|------------|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Done            | Completion | BOOL       | FALSE         | <p>This variable becomes TRUE when the control is completed.</p> <p>The value differs depending on the status of Start (Execute) at operation completion.</p> <p>■When Start (Execute) is TRUE</p> <p>This variable remains TRUE until Start (Execute) is set to FALSE.</p> <p>■When Start (Execute) is FALSE</p> <p>This variable becomes TRUE only for one cycle.</p> |
| Busy            | Executing  | BOOL       | FALSE         | This variable becomes TRUE when MCv_WriteProfileData (Profile Write) is executed.                                                                                                                                                                                                                                                                                       |
| Error           | Error      | BOOL       | FALSE         | This variable becomes TRUE when an error occurs.                                                                                                                                                                                                                                                                                                                        |
| ErrorID         | Error code | WORD(UINT) | 0             | <p>When an error occurs, this variable returns the error code.</p> <p>For details on error codes, refer to the following.</p> <p> User's manual for the controller used</p>                                                                                                          |
| ProfileID       | Profile ID | PROFILE_ID | 0             | The profile ID is output.                                                                                                                                                                                                                                                                                                                                               |

## Processing details

- This FB writes the operation profile data.
- The file specified in Profile data (ProfileData) and Write destination (Target), or the operation profile data in the open area are written for the number of points specified in Number of write data (Points) from the data specified with Offset (Offset).
- To write the whole operation profile data, specify "0" in both Offset (Offset) and Number of write data (Points).
- Write data is stored in variables specified in Write data 1 (Data1) and Write data 2 (Data2).

### ■Timing chart

- When the processing is completed successfully

- When the processing is completed with an error

For the timing chart, refer to the following.

👉 Page 1432 Basic operation of Execution command (Execute) type motion control FBs

## ■Offset (Offset) and Number of write data (Points) setting

The following operations are based on the values set in Offset (Offset) and Number of write data (Points).

The contents of the values set for Offset (Offset) and Number of write data (Points) vary depending on the operation profile data format.

The following describes the contents when "cam data" and "rotary cutter" are set to the operation profile data format.

- When the operation profile data format is "cam data"

| Specifying interpolation method (Interpolate) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                               |               |               |     |                              |                               |     |                              |                               |     |                              |                               |     |              |              |     |              |              |     |              |              |     |              |              |     |              |              |  |             |              |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |

| 0: Linear interpolation                       | <p>Sets the top of the coordinate for write in Offset (Offset), and the number of coordinates in Number of write points (Points). The data stored in Write data 1 (Data1) is the PROFILE_CAM_DATA type data when Specifying interpolation method (Interpolate) is "0: Linear interpolation". The data stored in Write data 2 (Data2) is data defined by using set coordinate data (a pair of input value (current value per cycle) and output value (stroke)) in LREAL type two-dimensional array.</p> <p>&lt;Example&gt;</p> <p>Write result of Write data 2 (Data2) when Offset (Offset) is set to "2" and Number of write data (Points) is set to "3". (When the variable set to Write data 2 (Data2) is a "LREAL[1..8,1..2]" data type "CamData2" label.)</p> <div><div><p>&lt;Variable (label/device)&gt;<br/>Two-dimensional array label of LREAL type<br/>(CamData2[1..8,1..2])</p><table><thead><tr><th></th><th>CamData[n][1]</th><th>CamData[n][2]</th></tr></thead><tbody><tr><td>n=1</td><td>Input value at the 2nd point</td><td>Output value at the 2nd point</td></tr><tr><td>n=2</td><td>Input value at the 3rd point</td><td>Output value at the 3rd point</td></tr><tr><td>n=3</td><td>Input value at the 4th point</td><td>Output value at the 4th point</td></tr><tr><td>n=4</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=5</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=6</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=7</td><td>Not updating</td><td>Not updating</td></tr><tr><td>n=8</td><td>Not updating</td><td>Not updating</td></tr></tbody></table></div><div><p>Offset</p><p>Number of write data (Points)</p></div><div><p>&lt;Open area/file&gt;*1</p><table><thead><tr><th></th><th>Input value</th><th>Output value</th></tr></thead><tbody><tr><td></td><td>at the 0th point</td><td>at the 0th point</td></tr><tr><td></td><td>at the 1st point</td><td>at the 1st point</td></tr><tr><td></td><td>at the 2nd point</td><td>at the 2nd point</td></tr><tr><td></td><td>at the 3rd point</td><td>at the 3rd point</td></tr><tr><td></td><td>at the 4th point</td><td>at the 4th point</td></tr><tr><td></td><td>at the 5th point</td><td>at the 5th point</td></tr><tr><td></td><td>at the 6th point</td><td>at the 6th point</td></tr><tr><td></td><td>at the 7th point</td><td>at the 7th point</td></tr></tbody></table></div></div> <p>*1: Depends on Read destination (Target).</p> |                               | CamData[n][1] | CamData[n][2] | n=1 | Input value at the 2nd point | Output value at the 2nd point | n=2 | Input value at the 3rd point | Output value at the 3rd point | n=3 | Input value at the 4th point | Output value at the 4th point | n=4 | Not updating | Not updating | n=5 | Not updating | Not updating | n=6 | Not updating | Not updating | n=7 | Not updating | Not updating | n=8 | Not updating | Not updating |  | Input value | Output value |  | at the 0th point | at the 0th point |  | at the 1st point | at the 1st point |  | at the 2nd point | at the 2nd point |  | at the 3rd point | at the 3rd point |  | at the 4th point | at the 4th point |  | at the 5th point | at the 5th point |  | at the 6th point | at the 6th point |  | at the 7th point | at the 7th point |

| 1: Specifying for each section                | <p>Specifying a section for write is not possible.</p> <p>Sets Offset (Offset) and Number of write data (Points) to "0", and writes the entire operation profile data. When a value other than "0" is set, Number of Offset/Read/Write Data Incorrect (error code: 1BADH) occurs. The data stored in Write data 1 (Data1) is the PROFILE_CAM_DATA type data when Specifying interpolation method (Interpolate) is "1: Specifying for each section" or "2: Spline interpolation". The data stored in Write data 2 (Data2) is section data defined in PROFILE_CAM_ELEMENT type array.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                               |               |               |     |                              |                               |     |                              |                               |     |                              |                               |     |              |              |     |              |              |     |              |              |     |              |              |     |              |              |  |             |              |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |  |                  |                  |

- When the operation profile data format is "rotary cutter"

Specifying a section for write is not possible. This format sets the Offset (Offset) and Number of write data (Points) to "0", and writes the entire operation profile data. The setting input manually for Offset (Offset) and the Number of write data (Points) is ignored. The data stored in Write data 1 (Data1) is data where the operation profile data format is PROFILE\_ROTARY\_CUTTER type "rotary cutter". Write data 2 (Data2) is not used.

- When the operation profile data format is "Multiple Axes Positioning Data"

| Write destination (Target)               | Description - When the operation profile data format is "Digital Cam Switch Data"

The top of the section to be written is set in Offset (Offset), and the Number of sections (NumberOfSections) in Number of write data (Points).

Specify PROFILE\_CAMSWITCH\_DATA type data in Write data 1 (Data1).

Specify the data for which the data of switch settings (FirstOnPosition, LastOnPosition, Direction, CamSwitchMode, and Duration) is defined as the PROFILE\_CAMSWITCH\_ELEMENT type array in Write data 2 (Data2).

Example:

Write result of Write data 2 (Data2) when Offset (Offset) is set to "0" and Number of write data (Points) is set to "3"  
(When the variable set to Write data 2 (Data2) is a "PROFILE\_CAMSWITCH\_ELEMENT[1..8]" data type  
"DigitalCamSwitchData2" label)

## ■Write data 1 (Data1)/Write data 2 (Data2)

Set write data of the operation profile data with a TARGET\_REF structure. The [VAR] and [DEV] data types can be used. For details on the TARGET\_REF structure, refer to the following.

📖 Page 1489 TARGET\_REF (Input signal)

For data types, write data structures of each operation profile data format can be used.

### • Write data 1 (Data1)

The operation profile data formats and data types set in Write data 1 (Data1) are shown below.

| Operation profile data format | Data type             | Reference                       |
|-------------------------------|-----------------------|---------------------------------|
| Cam data                      | PROFILE_CAM_DATA      | Page 1494 PROFILE_CAM_DATA      |
| Cam data for rotary cutter    | PROFILE_ROTARY_CUTTER | Page 1496 PROFILE_ROTARY_CUTTER |

### Ex.

When writing by using a device or label

#### • When writing a PROFILE\_CAM\_DATA type label (CamData1)

Data1.Target := "[VAR]CamData1"

#### • Write data 2 (Data2)

The operation profile data formats and data types set in Write data 2 (Data2) are shown below. The data type of the structure that is set varies depending on the Write destination (Target) and Specifying interpolation method (Interpolate) of the target cam data.

If the number of elements of the specified array is less than (the resolution + 1/number of coordinates) when the entire operation profile data is written, Number of Read/Write Data Mismatch (error code: 1BACH) occurs.

○: Supported, ×: Not supported

### Point

- If the type of the specified data structure for writing does not match the type that is required for each operation profile data, Read/Write Data Type Incorrect (error code: 1BAAH) occurs.
- For details on the cam data for the operation profile data set in Write data 1 (Data1)/Write data 2 (Data2), refer to the following.
  -  User's manual for the controller used
- If the Write destination (Target) of MCv\_WriteProfileData (Profile Write) is set to "1: File" with an LREAL type array and then data is written, the data is output to the file with Specifying interpolation method (Interpolate) for the cam data format set to "0: Linear Interpolation".

## ■Write destination (Target)

Sets the write destination of the operation profile data, and writes Write Data 1 (Data1)/Write Data 2 (Data2) and the Profile ID (PROFILE\_ID) of the operation profile data open FB.

| Setting value                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 2: Open area (motion service processing) | <ul style="list-style-type: none"> <li>The Profile ID (ID) value of the PROFILE_DATA structure is referred, and the write is performed for the operation profile data that Profile ID No. (Number) of the PROFILE_ID structure indicates in the open area.</li> <li>The write is performed at the cycle of the motion service processing.</li> </ul> <p>■When "0" is set in Profile ID No. (Number) of the PROFILE_ID structure<br/>An available ID is assigned automatically, and the ID is stored in profile ID No. (Number).<br/>If an FB with Profile ID No. (Number) specified as "0" is executed multiple times to the same operation profile data, the data will be opened in multiple different open areas.<br/>When no ID is available, Insufficient Operation Profile Data ID (error code: 1BA0H) will occur and open processing will not be performed.</p> <p>■When "1 to 60000" is set in Profile ID No. (Number) of the PROFILE_ID structure<br/>The set ID is opened without changing the ID.<br/>If setting an ID that has been already opened, the open data will be overwritten.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Point

- When Read destination (Target) is "1: File" or "2: Open area (motion service processing)", as motion service processing is used in that case, it may take much time for the processing to complete. Use Done (Execution completion) for the interlock as needed.
- When Target is set to "0: Open area", the processing is completed immediately as it is performed within the task where the FB is called. The program execution time increases when the number of write data points is too large. Therefore, execute the write multiple times with smaller data quantities as needed, or use the setting with Target set to "2: Open area (motion service processing)".

## ■ Execution mode (ExecutionMode)

Sets the timing for executing MCv\_WriteProfileData (Profile Write).

| Setting value                                 | Description                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0: Execute immediately<br>(mcImmediately)     | The contents of the open area are immediately written.<br>The writing may affect the control in execution.<br>Note that if the operation profile data format and resolution do not match when performing a write during FB execution, Operation Profile Data Being Operated (error code: 1B90H) occurs. |
| 1: Execute at completion (mcQueued)           | Waits for the FB being executed to complete, then performs writing.<br>When multiple FBs are waiting, the FBs will be executed in order of task priority.<br>FBs of the same priority are executed according to the start order.                                                                        |
| 3: Execute speculatively<br>(mcSpeculatively) | Operation profile data being operated (error code: 1B90H) occurs and the open area is not changed.                                                                                                                                                                                                      |

### Point

When no FB is in execution, the FB is executed immediately regardless of the setting of Execution mode (ExecutionMode).

When FBs in execution are accessing the open area, Executing (Busy) of each FB accessing the open area becomes TRUE. Use Execution mode (ExecutionMode) for the interlock as needed.

## Precautions

The number of data points that can be written at the same time are limited. If the write is not completed in a single FB execution, execute the write over several FB executions.

## Program example

The following is a program example. "LREAL type (two-dimensional array) format" cam data 1 (ProfileData0001) and "PROFILE\_CAM\_ELEMENT format" cam data 2 (ProfileData0002) are written to the file.

### ■Operation profile data

| Profile ID | Label name      | Data type  | Comment    |
|------------|-----------------|------------|------------|
| 1          | ProfileData0001 | MC_CAM_REF | Cam data 1 |
| 2          | ProfileData0002 | MC_CAM_REF | Cam data 2 |

#### • Operation profile data (cam data) settings

| Item                            |                  | ProfileData0001      | ProfileData0002             |
|---------------------------------|------------------|----------------------|-----------------------------|

# 48 FUNCTION BLOCKS FOR Ethernet

## Point

The function blocks in this chapter are controller module FBs. Use them from [Module] ⇒ [Module FB] of the Element Selection window of the engineering tool.

## 48.1 Opening/Disconnecting a Connection

### M+MXF-SQ\_ConnectionOpen

Opens (establishes) a connection.

To specify the encrypted predefined protocols (TLS and DTLS), the external device must also support them.

### Setting data

#### ■Input arguments

| Variable name   | Name              | Data type                           | Range   | Description                                                                      |
|-----------------|-------------------|-------------------------------------|---------|----------------------------------------------------------------------------------|
| i_bEN           | Execution command | Bit                                 | —       | On: Start FB.<br>Off: Do not start FB.                                           |
| i_stModule      | Module label      | Structure                           | —       | Specify the module label of the controller executing the FB.<br>(Example: MX_SQ) |
| i_uConnectionNo | Connection No.    | Word [unsigned]/bit string [16-bit] | 1 to 64 | Specify the number of the connection to be opened.                               |

#### ■Output arguments

| Variable name | Name              | Data type                           | Description                                                                          | Default value |
|---------------|-------------------|-------------------------------------|--------------------------------------------------------------------------------------|---------------|
| o_bENO        | Execution status  | Bit                                 | On: The execution command is turned on.<br>Off: The execution command is turned off. | Off           |
| o_bOK         | Normal completion | Bit                                 | The FB has been processed normally when this argument is on.                         | Off           |
| o_bErr        | Error completion  | Bit                                 | The FB has been processed abnormally when this argument is on.                       | Off           |
| o_uErrId      | Error code        | Word [unsigned]/bit string [16-bit] | An error code is stored at error completion.                                         | 0             |

## ■Operation parameters

| Variable name       | Name                           | Data type                                  | Range                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Default value           |
|---------------------|--------------------------------|--------------------------------------------|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| pbi_bUseParameters  | Parameter used                 | Bit                                        | On or off                                           | Specify whether to use the parameter values set by the engineering tool or the following operation parameter values when processing for opening a connection.<br>• Off: Performs open processing according to the external device configuration setting made by the engineering tool. (The following operation parameters need not be set. Any settings are ignored if made.)<br>• On: Performs open processing according to the following operation parameters. | Off                     |
| pbi_uProtocol       | Protocol                       | Word [unsigned]/bit string [16-bit]        | 0 to 3                                              | Select the protocol to be used for the connection to be opened.<br>• pbi_uPredefProtocol (predefined protocol setting) is 0<br>0: TCP<br>1: UDP<br>2: TLS<br>3: DTLS<br>• pbi_uPredefProtocol (predefined protocol setting) is 1<br>0: TCP<br>1: UDP                                                                                                                                                                                                             | 0                       |
| pbi_uOpen_System    | Open method                    | Word [unsigned]/bit string [16-bit]        | 0 to 2                                              | Select the connection open method.<br>• 0: Active open or UDP or DTLS<br>• 1: Unpassive open<br>• 2: Fullpassive open                                                                                                                                                                                                                                                                                                                                            | 0                       |
| pbi_uPredefProtocol | Communication protocol setting | Word [unsigned]/bit string [16-bit]        | 0 to 1                                              | Select whether to use the predefined protocol function.<br>• 0: Do not use the predefined protocol support function. (Use the socket communications function.)<br>• 1: Use the predefined protocol support function.                                                                                                                                                                                                                                             | 0                       |
| pbi_uLocal_Port_No  | Own node port number           | Word [unsigned]/bit string [16-bit]        | 1 to 4999, 5010 to 65534                            | Specify the port number of the own node. Port numbers 1 to 1023 are generally reserved port numbers (WELL KNOWN PORT NUMBERS), and therefore port numbers 1024 to 4999 and 5010 to 65534 should be used.                                                                                                                                                                                                                                                         | 4096                    |
| pbi_uTarget_Port_No | Destination port number        | Word [unsigned]/bit string [16-bit]        | 1 to 65534, 65535                                   | Specify the destination port number. With the connection that is assigned port No.65535 (only when the UDP or DTLS protocol is selected), data is received through all port numbers. Data cannot be sent with the connection which is assigned port No.65535 and therefore a port number from 1 to 65534 should be specified to send data.                                                                                                                       | 4096                    |
| pbi_u2IP_Address    | IP address of external device  | Word [unsigned]/bit string [16-bit] (0..1) | 0.0.0.1 to 255.255.255.255 (00000001H to FFFFFFFFH) | Specify the IP address of an external device.<br>Specify the third and fourth octets to the 1st word, and first and second octets to the 2nd word.<br>Specify 255.255.255.255 (FFFFFFFH) when performing simultaneous broadcast.<br><div><div></div><div><div>b15b8b7b0</div><div>+0<div>(3)(4)</div></div><div>+1<div>(1)(2)</div></div></div><br/>(1) to (4): IP address octet</div> <td>192.168.1.1 (C0A80101H)</td>                                          | 192.168.1.1 (C0A80101H) |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Precautions | <p>■ Specifications of the FBs</p> <ul style="list-style-type: none"> <li>• This module FB cannot be executed for the connection that is being used by another module FB or a dedicated instruction. An error occurs if this module FB is executed for the connection in use.</li> <li>• When open processing is performed according to the content of the operation parameter with pbi_bUseParameters (parameter used) set to ON, the available communication means is the socket communications and predefined protocols only.</li> <li>• If this FB is executed for the connection for which parameters are already set by "External Device Connection Configuration Setting", conduct open processing based on the operation parameters specified by this FB.</li> <li>• This FB uses the label initial value by each program. When the program file using this FB is specified to boot file setting for the boot operation in the controller, specify the initial label value file by each program to the boot file setting as well. If an error code that is not described in  Page 1989 Error codes appears, the initial label value files by each program may not be set correctly. In this case, specify the initial label value files by each program to the boot file setting.</li> <li>• When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> <p>■ Operations of the FBs</p> <ul style="list-style-type: none"> <li>• Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> </ul> |

## ■ Error codes

The error code occurred by this FB is the same as the SOCOPEN instruction.

 Page 1146 GP.SOCOPEN, SP.SOCOPEN

## M+MXF-SQ\_ConnectionClose

Closes (disconnects) the connection.

### ST

```

M_MXF_SQ_ConnectionClose(
    i_bEN:= ?BOOL? ,
    i_stModule:= ?M+MX_SQ? ,
    i_uConnectionNo:= ?WORD? ,
    o_bENO=> ?BOOL? ,
    o_bOK=> ?BOOL? ,
    o_bErr=> ?BOOL? ,
    o_uErrId=> ?WORD?
);

```

### Setting data

#### Input arguments

| Variable name   | Name              | Data type                           | Range          | Description                                                                                                               |
|-----------------|-------------------|-------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------|
| i_bEN           | Execution command | Bit                                 | —              | On: Start FB.<br>Off: Do not start FB.                                                                                    |
| i_stModule      | Module label      | Structure                           | —              | Specify the module label of the controller executing the FB.<br>(Example: MX_SQ)                                          |
| i_uConnectionNo | Connection No.    | Word [unsigned]/bit string [16-bit] | 1 to 64, 65535 | Specify the number of the connection to be closed.<br>This function closes all connections if 65535 (FFFFH) is specified. |

#### Output arguments

| Variable name | Name              | Data type                           | Description                                                                          | Default value |
|---------------|-------------------|-------------------------------------|--------------------------------------------------------------------------------------|---------------|
| o_bENO        | Execution status  | Bit                                 | On: The execution command is turned on.<br>Off: The execution command is turned off. | Off           |
| o_bOK         | Normal completion | Bit                                 | The FB has been processed normally when this argument is on.                         | Off           |
| o_bErr        | Error completion  | Bit                                 | The FB has been processed abnormally when this argument is on.                       | Off           |
| o_uErrId      | Error code        | Word [unsigned]/bit string [16-bit] | An error code is stored at error completion.                                         | 0             |

#### Public variables

| Variable name   | Name                 | Data type                           | Description                                                                                                                                                                                                                                                                 | Default value |
|-----------------|----------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| pbo_uErrConn_No | Error connection No. | Word [unsigned]/bit string [16-bit] | The number of the connection for which close processing was completed with an error is stored.<br>If 65535 (FFFFH) is specified in "Connection No." (i_uConnectionNo), the number of the connection for which close processing was first completed with an error is stored. | 0             |

## Processing details

| Item                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                      |

| Precautions                 | <ul style="list-style-type: none"> <li>This module FB cannot be executed for the connection that is being used by another module FB or a dedicated instruction. An error occurs if this module FB is executed for the connection in use.</li> <li>Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrld (error code) is cleared to 0.</li> <li>When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |                                      |

## Operation error

The error code occurred by this FB is the same as the SOCCLOSE instruction.

 Page 1150 GP.SOCCLOSE, SP.SOCCLOSE

# 48.2 Socket Communications

## M+MXF-SQ\_Recv\_Socket

Reads the data received from the external device through socket communications.

### ST

```
M_MXF_SQ_Recv_Socket(
    i_bEN:= ?BOOL? ,
    i_stModule:= ?M+MX_SQ? ,
    i_uConnectionNo:= ?WORD? ,
    o_bENO=> ?BOOL? ,
    o_bOK=> ?BOOL? ,
    o_bErr=> ?BOOL? ,
    o_uErrId=> ?WORD? ,
    o_uRecvData=> ?WORD?
);
```

### Setting data

#### Input arguments

| Variable name   | Name              | Data type                                 | Range   | Description                                                                      |
|-----------------|-------------------|-------------------------------------------|---------|----------------------------------------------------------------------------------|
| i_bEN           | Execution command | Bit                                       | —       | On: Start FB.<br>Off: Do not start FB.                                           |
| i_stModule      | Module label      | Structure                                 | —       | Specify the module label of the controller executing the FB.<br>(Example: MX_SQ) |
| i_uConnectionNo | Connection No.    | Word<br>[unsigned]/bit<br>string [16-bit] | 1 to 64 | Specify the number of the connection to be received.                             |

| Precautions                 | <ul style="list-style-type: none"> <li>This module FB cannot be executed for the connection that is being used by another module FB or a dedicated instruction. An error occurs if this module FB is executed for the connection in use.</li> <li>Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrld (error code) is cleared to 0.</li> <li>The execution command of this FB can be executed at any timing. However, when executing it after receiving data, G7889 to G7892 (Socket communications reception status signal) or corresponding module label must be added to conditions of the execution.</li> <li>When the module FB is executed by specifying ON (start reading in the first END processing after the FB starts) in operation parameter "Read timing", the module FB extends the scan time to complete data read processing within one END processing.</li> <li>This FB uses the label initial value by each program. When the program file using this FB is specified to boot file setting for the boot operation in the controller, specify the initial label value file by each program to the boot file setting as well. If an error code that is not described in <a href="#">Page 1995 Error codes</a> appears, the initial label value files by each program may not be set correctly. In this case, specify the initial label value files by each program to the boot file setting.</li> <li>When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |                                      |

## ■Error codes

The error code occurred by this FB is the same as the SOCRCV instruction or SOCRCVS instruction.

☞ Page 1157 G.SOCRCVS, S.SOCRCVS

M+MXF-SQ\_Send\_Socket

Sends data to the external device through socket communications.

ST

```
M_MXF_SQ_Send_Socket(  
  i_bEN:= ?BOOL? ,  
  i_stModule:= ?M+MX_SQ? ,  
  i_uConnectionNo:= ?WORD? ,  
  i_uSendData:= ?WORD? ,  
  o_bENO=> ?BOOL? ,  
  o_bOK=> ?BOOL? ,  
  o_bErr=> ?BOOL? ,  
  o_uErrId=> ?WORD?  
);
```

## Input arguments

| Precautions                 | <ul style="list-style-type: none"> <li>This module FB cannot be executed for the connection that is being used by another module FB or a dedicated instruction. An error occurs if this module FB is executed for the connection in use.</li> <li>Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> <li>When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |                                      |

## Operation error

The error code occurred by this FB is the same as the SOCSND instruction.

 Page 1160 GP.SOCSND, SP.SOCSND

## M+MXF-SQ\_SLMP\_DeviceRead\_IP

Reads device data from the SLMP-compatible device specified by an IP address.

The external device must support SLMP command (Device Read).

For encrypted communications, the external device must support the encrypted predefined protocol (DTLS) in addition to the above.

\*1 For details on each device code, refer to the following.

SLMP Reference Manual

\*2 Give the serial numbers when sending several request messages to the same SLMP-compatible device. Serial numbers to be given are automatically numbered by the system. For the serial number, refer to the following.

SLMP Reference Manual

## ■Output arguments

| Variable name | Name                          | Data type                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Default value |   |   |   |     |  |  |  |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

| pbo_uErrIP_Address_1st_2nd | IP address of error detected station (first and second octets) | Word [unsigned]/bit string [16-bit] (0..1) | The IP addresses (the first and second octets) of the station in which an error was detected are stored.*1<br>Example: When the IP address is 192.168.1.2<br>C0A8h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0             |

\*1 The value is stored only when the dedicated instruction was completed with an error.

The value set to the target station address of the input argument is stored in the error-detected device IP addresses (the third and fourth octets) and the error-detected device IP addresses (the first and second octets).

## Processing details

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Precautions | <ul style="list-style-type: none"> <li>This FB does not include error recovery processing. Please create error recovery processing separately according to the system and required operations.</li> <li>This FB uses the SLMPSND instruction or SLMPSNDC instruction. The SLMPSND instruction and SLMPSNDC instruction are successfully completed even if the target device returns an abnormal response. Therefore, in this FB, the instruction is determined to be completed successfully or completed with an error by the end code of the response frame in addition to the completion status of the dedicated instruction. If the instruction is determined as completed with an error by the end code, check that the end code is stored in o_uErrId (error code), and 0 (initial value) is stored in pbo_u4ErrTime (error occurrence time), pbo_uErrIP_Address_3rd_4th (error detection device IP address (3rd and 4th octets)) and pbo_uErrIP_Address_1st_2nd (error detection device IP address (1st and 2nd octets)). For the cause of the error, refer the manual for the SLMP-compatible device being used, and take corrective action. (SLMP Reference Manual)</li> <li>Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> <li>In this FB, access devices (such as link direct device) that are accessed by the extension specification of the SLMP cannot be read.</li> <li>In this FB, stations in other network cannot be set as the target station.</li> <li>When this FB is executed for the port of an external device where the remote password is set, execute this FB after performing the unlock processing of the remote password. When this FB is executed for the port of an external device where the remote password is set, an error will occur.</li> <li>The target station must support "Read (command: 0401)" of the SLMP command.</li> <li>This FB is for communications in binary code only. (Communications using ASCII code cannot be performed.)</li> <li>This FB uses UDP or DTLS communications. The external device must have the same settings.</li> <li>This FB uses the label initial value by each program. When the program file using this FB is specified to boot file setting for the boot operation in the controller, specify the initial label value file by each program to the boot file setting as well. If an error code that is not described in  Page 2005 Error codes appears, the initial label value files by each program may not be set correctly. In this case, specify the initial label value files by each program to the boot file setting.</li> <li>When pbi_bEncryptionComm (whether to use the encrypted communications) is on (enabled), the value set to pbi_uLocal_Port_No (own node port number) must not be the same as the value set to "PLC Port No." set in "External Device Configuration" in the module parameter (Ethernet). If the configured port numbers are overlapped, this FB may complete with an error.</li> <li>When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |

## ■Error codes

| Error code  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     | Action                                                                                   |

| 100H        | A value out of the range is set in the number of device points (i_uDevicePoints) of the argument.                                                                                                                                                                                                                                                                                                                                               | Set the value within the setting range in the number of device points (i_uDevicePoints). |
| Except 100H | <p>Check the error code of the SLMPSND instruction and take actions.</p> <p> Page 1184 G(P).SLMPSND, J(P).SLMPSND, SP.SLMPSND</p> <p>For encrypted communication, check the error code of the SLMPSNDC instruction, and take actions.</p> <p> Page 1194 G(P).SLMPSNDC</p> |                                                                                          |

# M+MXF-SQ\_SLMP\_DeviceWrite\_IP

Writes device data to the SLMP-compatible device specified by an IP address.  
The external device must support SLMP command (Device Write).  
For encrypted communications, the external device must support the encrypted predefined protocol (DTLS) in addition to the above.

| i_uTarget_Port_No | Destination port number        | Word [unsigned]/bit string [16-bit] | 1 to 65534 | <p>Specify the UDP port number or DTLS port number of an external device.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

\*1 For details on each device code, refer to the following.

📖 SLMP Reference Manual

\*2 Give the serial numbers when sending several request messages to the same SLMP-compatible device. Serial numbers to be given are automatically numbered by the system. For the serial number, refer to the following.

📖 SLMP Reference Manual

## ■Output arguments

| Variable name | Name              | Data type                           | Description                                                                          | Default value |
|---------------|-------------------|-------------------------------------|--------------------------------------------------------------------------------------|---------------|
| o_bENO        | Execution status  | Bit                                 | On: The execution command is turned on.<br>Off: The execution command is turned off. | Off           |
| o_bOK         | Normal completion | Bit                                 | The FB has been processed normally when this argument is on.                         | Off           |
| o_bErr        | Error completion  | Bit                                 | The FB has been processed abnormally when this argument is on.                       | Off           |
| o_uErrId      | Error code        | Word [unsigned]/bit string [16-bit] | An error code is stored at error completion.                                         | 0             |

## ■Operation parameters

| Variable name        | Name                                   | Data type                           | Range                    | Description                                                                                                                                                                                                                                                                                                                 | Default value |
|----------------------|----------------------------------------|-------------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| pbi_uRequestModuleIO | Requested module I/O No.               | Word [unsigned]/bit string [16-bit] | 03E0H to 03E3H, 03FFH    | Specify the module of the access destination.<br>• 03FFH: Own station, control CPU<br>• 03E0H: Multiple CPU No.1<br>• 03E1H: Multiple CPU No.2<br>• 03E2H: Multiple CPU No.3<br>• 03E3H: Multiple CPU No.4                                                                                                                  | 03FFH         |
| pbi_uResendCountMax  | Maximum number of resends              | Word [unsigned]/bit string [16-bit] | 0 to 15                  | Specify the number of resends to be performed if the data transfer is not completed within the monitoring time specified by pbi_uMonitorTime (Arrival monitoring time).<br>• 0 to 15                                                                                                                                        | 5             |
| pbi_uMonitorTime     | Arrival monitoring time                | Word [unsigned]/bit string [16-bit] | 0, 1 to 32767            | Specify the monitoring time until completion of processing. If the processing is not completed within the monitoring time, data is resent until the value specified in pbi_uResendCountMax (Maximum number of resends) is reached.<br>• 0: 10s<br>• 1 to 32767: 1 to 32767s                                                 | 0             |
| pbi_bEncryptionComm  | Encrypted communication enable/disable | Bit string                          | On or off                | Specify whether SLMP frames are encrypted or not.<br>• On: Enable (Encrypt)<br>• Off: Disable (Do not encrypt)                                                                                                                                                                                                              | Off           |
| pbi_uLocal_Port_No   | Own node port number                   | Word [unsigned]/bit string [16-bit] | 1 to 4999, 5010 to 65534 | Specify the port number of the own node. Port numbers 1 to 1023 are generally reserved port numbers (WELL KNOWN PORT NUMBERS), and therefore port numbers 1024 to 4999 and 5010 to 65534 should be used.<br>The specified value is valid only when pbi_bEncryptionComm (whether to use the encrypted communications) is ON. | 4096          |

| pbo_uErrIP_Address_3rd_4th | IP address of error detected station (third and fourth octets) | Word [unsigned]/bit string [16-bit] (0..1) | The IP addresses (the third and fourth octets) of the station in which an error was detected are stored.*1<br>Example: When the IP address is 192.168.1.2<br>0102h                                                                                                                                                                                                                                                                                                               | 0             |
| pbo_uErrIP_Address_1st_2nd | IP address of error detected station (first and second octets) | Word [unsigned]/bit string [16-bit] (0..1) | The IP addresses (the first and second octets) of the station in which an error was detected are stored.*1<br>Example: When the IP address is 192.168.1.2<br>C0A8h                                                                                                                                                                                                                                                                                                               | 0             |

\*1 The value is stored only when the dedicated instruction was completed with an error.  
The value set to the target station address of the input argument is stored in the error-detected device IP addresses (the third and fourth octets) and the error-detected device IP addresses (the first and second octets).

## Processing details

| Item                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Precautions | <ul style="list-style-type: none"> <li>This FB does not include error recovery processing. Please create error recovery processing separately according to the system and required operations.</li> <li>This FB uses the SLMPSEND instruction or SLMPSENDNC instruction. The SLMPSEND instruction and SLMPSENDNC instruction are successfully completed even if the target device returns an abnormal response. Therefore, in this FB, the instruction is determined to be completed successfully or completed with an error by the end code of the response frame in addition to the completion status of the dedicated instruction. If the instruction is determined as completed with an error by the end code, check that the end code is stored in o_uErrId (error code), and 0 (initial value) is stored in pbo_u4ErrTime (error occurrence time), pbo_uErrIP_Address_3rd_4th (error detection device IP address (3rd and 4th octets)) and pbo_uErrIP_Address_1st_2nd (error detection device IP address (1st and 2nd octets)). For the cause of the error, refer the manual for the SLMP-compatible device being used, and take corrective action. (SLMP Reference Manual)</li> <li>Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> <li>In this FB, access devices (such as link direct device) that are accessed by the extension specification of the SLMP cannot be written.</li> <li>In this FB, stations in other network cannot be set as the target station.</li> <li>When this FB is executed for the port of an external device where the remote password is set, execute this FB after performing the unlock processing of the remote password. When this FB is executed for the port of an external device where the remote password is set, an error will occur.</li> <li>The target station must support "Write (command: 1401)" of the SLMP command.</li> <li>This FB is for communications in binary code only. (Communications using ASCII code cannot be performed.)</li> <li>This FB uses UDP or DTLS communications. The external device must have the same settings.</li> <li>This FB uses the label initial value by each program. When the program file using this FB is specified to boot file setting for the boot operation in the controller, specify the initial label value file by each program to the boot file setting as well. If an error code that is not described in  Page 2012 Error codes appears, the initial label value files by each program may not be set correctly. In this case, specify the initial label value files by each program to the boot file setting.</li> <li>When pbi_bEncryptionComm (whether to use the encrypted communications) is on (enabled), the value set to pbi_uLocal_Port_No (own node port number) must not be the same as the value set to "PLC Port No." set in "External Device Configuration" in the module parameter (Ethernet). If the configured port numbers are overlapped, this FB may complete with an error.</li> <li>When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |

## ■Error codes

| Error code  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             | Action                                                                                   |

## M+MXF-TSN\_SLMP\_DeviceRead\_IP

Reads device data from the SLMP-compatible device specified by an IP address.

The external device must support SLMP command (Device Read).

### ST

```

| pbo_uErrIP_Address_1st_2nd | IP address of error detected station (first and second octets) | Word [unsigned]/bit string [16-bit] (0..1) | The IP addresses (the first and second octets) of the station in which an error was detected are stored.*1<br>Example: When the IP address is 192.168.1.2<br>C0A8h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 0             |

\*1 The value is stored only when the dedicated instruction was completed with an error.

The value set to the target station address of the input argument is stored in the error-detected device IP addresses (the third and fourth octets) and the error-detected device IP addresses (the first and second octets).

| Item                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                |

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Precautions | <ul style="list-style-type: none"> <li>This FB does not include error recovery processing. Please create error recovery processing separately according to the system and required operations.</li> <li>This FB uses the SLMPSEND instruction. The SLMPSEND instruction is successfully completed even if the target device returns an abnormal response. Therefore, in this FB, the instruction is determined to be completed successfully or completed with an error by the end code of the response frame in addition to the completion status of the dedicated instruction. If the instruction is determined as completed with an error by the end code, check that the end code is stored in o_uErrId (error code), and 0 (initial value) is stored in pbo_u4ErrTime (error occurrence time), pbo_uErrIP_Address_3rd_4th (error detection device IP address (3rd and 4th octets)) and pbo_uErrIP_Address_1st_2nd (error detection device IP address (1st and 2nd octets)). For the cause of the error, refer the manual for the SLMP-compatible device being used, and take corrective action. (SLMP Reference Manual)</li> <li>Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> <li>In this FB, access devices (such as link direct device) that are accessed by the extension specification of the SLMP cannot be read.</li> <li>In this FB, stations in other network cannot be set as the target station.</li> <li>When this FB is executed for the port of an external device where the remote password is set, execute this FB after performing the unlock processing of the remote password. When this FB is executed for the port of an external device where the remote password is set, an error will occur.</li> <li>The target station must support "Read (command: 0401)" of the SLMP command.</li> <li>This FB is for communications in binary code only. (Communications using ASCII code cannot be performed.)</li> <li>This FB uses UDP communications. The external device must have the same settings.</li> <li>This FB uses the label initial value by each program. When the program file using this FB is specified to boot file setting for the boot operation in the controller, specify the initial label value file by each program to the boot file setting as well. If an error code that is not described in Page 2019 Error codes appears, the initial label value files by each program may not be set correctly. In this case, specify the initial label value files by each program to the boot file setting.</li> <li>When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |

## ■Error codes

| Error code  | Description                                                                                                               | Action                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| 100H        | A value out of the range is set in the number of device points (i_uDevicePoints) of the argument.                         | Set the value within the setting range in the number of device points (i_uDevicePoints). |
| Except 100H | Check the error code of the SLMPSEND instruction and take actions.<br>Page 1184 G(P).SLMPSEND, J(P).SLMPSEND, SP.SLMPSEND |                                                                                          |

## M+MXF-TSN\_SLMP\_DeviceWrite\_IP

Writes device data to the SLMP-compatible device specified by an IP address.

The external device must support SLMP command (Device Write).

### ST

```

M_MXF_TSN_SLMP_DeviceWrite_IP(
    i_bEN:= ?BOOL? ,
    i_stModule:= ?M+MX_TSN? ,
    i_u2IP_Address:= ?WORD(0..1)? ,
    i_uSubCommand:= ?WORD? ,
    i_uDeviceCode:= ?WORD? ,
    i_u2DeviceNo:= ?WORD(0..1)? ,
    i_uDevicePoints:= ?WORD? ,
    i_uWriteData:= ?WORD? ,
    i_uChannel:= ?WORD? ,
    i_uTarget_Port_No:= ?WORD? ,
    o_bENO=> ?BOOL? ,
    o_bOK=> ?BOOL? ,
    o_bErr=> ?BOOL? ,
    o_uErrId=> ?WORD?
);

```

## ■Input arguments

\*1 For details on each device code, refer to the following.

📖 SLMP Reference Manual

## ■Output arguments

| Variable name | Name              | Data type                           | Description                                                                          | Default value |
|---------------|-------------------|-------------------------------------|--------------------------------------------------------------------------------------|---------------|
| o_bENO        | Execution status  | Bit                                 | On: The execution command is turned on.<br>Off: The execution command is turned off. | Off           |
| o_bOK         | Normal completion | Bit                                 | The FB has been processed normally when this argument is on.                         | Off           |
| o_bErr        | Error completion  | Bit                                 | The FB has been processed abnormally when this argument is on.                       | Off           |
| o_uErrId      | Error code        | Word [unsigned]/bit string [16-bit] | An error code is stored at error completion.                                         | 0             |

## ■Operation parameters

| Variable name        | Name                      | Data type                           | Range                 | Description                                                                                                                                                                                                                                                                 | Default value |
|----------------------|---------------------------|-------------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| pbi_uRequestModuleIO | Requested module I/O No.  | Word [unsigned]/bit string [16-bit] | 03E0H to 03E3H, 03FFH | Specify the module of the access destination.<br>• 03FFH: Own station, control CPU<br>• 03E0H: Multiple CPU No.1<br>• 03E1H: Multiple CPU No.2<br>• 03E2H: Multiple CPU No.3<br>• 03E3H: Multiple CPU No.4                                                                  | 03FFH         |
| pbi_uResendCountMax  | Maximum number of resends | Word [unsigned]/bit string [16-bit] | 0 to 15               | Specify the number of resends to be performed if the data transfer is not completed within the monitoring time specified by pbi_uMonitorTime (Arrival monitoring time).<br>• 0 to 15                                                                                        | 5             |
| pbi_uMonitorTime     | Arrival monitoring time   | Word [unsigned]/bit string [16-bit] | 0, 1 to 32767         | Specify the monitoring time until completion of processing. | pbo_uErrIP_Address_3rd_4th | IP address of error detected station (third and fourth octets) | Word [unsigned]/bit string [16-bit] (0..1) | The IP addresses (the third and fourth octets) of the station in which an error was detected are stored.*1<br>Example: When the IP address is 192.168.1.2<br>0102h                                                                                                                                                                                                                                                                                                               | 0             |
| pbo_uErrIP_Address_1st_2nd | IP address of error detected station (first and second octets) | Word [unsigned]/bit string [16-bit] (0..1) | The IP addresses (the first and second octets) of the station in which an error was detected are stored.*1<br>Example: When the IP address is 192.168.1.2<br>C0A8h                                                                                                                                                                                                                                                                                                               | 0             |

\*1 The value is stored only when the dedicated instruction was completed with an error.

The value set to the target station address of the input argument is stored in the error-detected device IP addresses (the third and fourth octets) and the error-detected device IP addresses (the first and second octets).

## Processing details

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Precautions | <ul style="list-style-type: none"> <li>• This FB does not include error recovery processing. Please create error recovery processing separately according to the system and required operations.</li> <li>• This FB uses the SLMPSEND instruction. The SLMPSEND instruction is successfully completed even if the target device returns an abnormal response. Therefore, in this FB, the instruction is determined to be completed successfully or completed with an error by the end code of the response frame in addition to the completion status of the dedicated instruction. If the instruction is determined as completed with an error by the end code, check that the end code is stored in o_uErrId (error code), and 0 (initial value) is stored in pbo_u4ErrTime (error occurrence time), pbo_uErrIP_Address_3rd_4th (error detection device IP address (3rd and 4th octets)) and pbo_uErrIP_Address_1st_2nd (error detection device IP address (1st and 2nd octets)). For the cause of the error, refer the manual for the SLMP-compatible device being used, and take corrective action. (SLMP Reference Manual)</li> <li>• Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> <li>• In this FB, access devices (such as link direct device) that are accessed by the extension specification of the SLMP cannot be written.</li> <li>• In this FB, stations in other network cannot be set as the target station.</li> <li>• When this FB is executed for the port of an external device where the remote password is set, execute this FB after performing the unlock processing of the remote password. When this FB is executed for the port of an external device where the remote password is set, an error will occur.</li> <li>• The target station must support "Write (command: 1401)" of the SLMP command.</li> <li>• This FB is for communications in binary code only. (Communications using ASCII code cannot be performed.)</li> <li>• This FB uses UDP communications. The external device must have the same settings.</li> <li>• This FB uses the label initial value by each program. When the program file using this FB is specified to boot file setting for the boot operation in the controller, specify the initial label value file by each program to the boot file setting as well. If an error code that is not described in Page 2026 Error codes appears, the initial label value files by each program may not be set correctly. In this case, specify the initial label value files by each program to the boot file setting.</li> <li>• When this FB is executed, an operation error may occur in the controller. In this case, check the detailed information of the operation error in event history and correct the input argument of the module FB.</li> </ul> |

## ■Error codes

| Error code  | Description                                                                                                               | Action                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| 100H        | A value out of the range is set in the number of device points (i_uDevicePoints) of the argument.                         | Set the value within the setting range in the number of device points (i_uDevicePoints). |
| Except 100H | Check the error code of the SLMPSEND instruction and take actions.<br>Page 1184 G(P).SLMPSEND, J(P).SLMPSEND, SP.SLMPSEND |                                                                                          |

Point

The function blocks in this chapter are controller module FBs. Use them from [Module] ⇒ [Module FB] of the Element Selection window of the engineering tool.

49.1 Remote Reset

M+MXF-TSN\_RemoteReset2\_IP

Sends the remote RESET of an SLMP request to the target station specified by an IP address.

\*1 To perform communications using the frame without the serial number on this FB, specify 1 to the own station channel. When a number of 2 to 9 is specified, this FB communicates using the frame with the serial number. When a number of 10 to 17 is specified, this FB communicates using the station number extension frame.

### Output arguments

| Variable name | Name              | Data type                           | Description                                                                          | Default value |
|---------------|-------------------|-------------------------------------|--------------------------------------------------------------------------------------|---------------|
| o_bENO        | Execution status  | Bit                                 | On: The execution command is turned on.<br>Off: The execution command is turned off. | Off           |
| o_bOK         | Normal completion | Bit                                 | The FB has been processed normally when this argument is on.                         | Off           |
| o_bErr        | Error completion  | Bit                                 | The FB has been processed abnormally when this argument is on.                       | Off           |
| o_uErrId      | Error code        | Word [unsigned]/bit string [16-bit] | An error code is stored at error completion.                                         | 0             |

## Public variables

| Variable name                | Name                                                             | Data type                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Default value |
|------------------------------|------------------------------------------------------------------|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| pbo_u4ErrTime                | Error occurrence time                                            | Word [unsigned]/bit string [16-bit] (0..3) | Clock data at the time of error occurrence is stored. <sup>*1</sup><br>1st word<br>• Upper 8 bits: Month (01H to 12H)<br>• Lower 8 bits: Lower 2 digits of year (00H to 99H)<br>2nd word<br>• Upper 8 bits: Hour (00H to 23H)<br>• Lower 8 bits: Day (01H to 31H)<br>3rd word<br>• Upper 8 bits: Second (00H to 59H)<br>• Lower 8 bits: Minute (00H to 59H)<br>4th word<br>• Upper 8 bits: Upper 2 digits of year (00H to 99H)<br>• Lower 8 bits: Day of week (00H (Sunday) to 06H (Saturday)) | 0             |
| pbo_uErrIP_Addresses_3rd_4th | Error-detected device IP addresses (the third and fourth octets) | Word [unsigned]/bit string [16-bit]        | The IP addresses (the third and fourth octets) of the station in which an error was detected are stored. <sup>*1</sup><br>Example: When the IP address is 192.168.1.2<br>0102h                                                                                                                                                                                                                                                                                                                 | 0             |
| pbo_uErrIP_Addresses_1st_2nd | Error-detected device IP addresses (the first and second octets) | Word [unsigned]/bit string [16-bit]        | The IP addresses (the first and second octets) of the station in which an error was detected are stored. <sup>*1</sup><br>Example: When the IP address is 192.168.1.2<br>C0A8h                                                                                                                                                                                                                                                                                                                 | 0             |

<sup>\*1</sup> The value is stored only when the dedicated instruction was completed with an error.  
 The value set to the target station address of the input argument is stored in the error-detected device IP addresses (the third and fourth octets) and the error-detected device IP addresses (the first and second octets).

## Processing details

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Precautions | <ul style="list-style-type: none"> <li>• This FB does not include error recovery processing. Please create error recovery processing separately according to the system and required operations.</li> <li>• This FB uses the SLMPSND instruction. Even if the target device has sent an abnormal response, the SLMPSND instruction is completed successfully.</li> <li>• When the SLMPSND instruction is completed successfully, the values are not stored to the error occurrence time of the public variable, pbo_uErrIP_Address_3rd_4th (error-detected device IP addresses (the third and fourth octets)), and pbo_uErrIP_Address_1st_2nd (error-detected device IP addresses (the first and second octets)).<sup>*1</sup></li> <li>• Turn off i_bEN (execution command) after o_bOK (normal completion) or o_bErr (error completion) is turned on. By turning off i_bEN (execution command), o_bOK (normal completion) or o_bErr (error completion) is turned off and o_uErrId (error code) is cleared to 0.</li> <li>• When the remote RESET request is sent and completed successfully, o_bOK (normal completion) is turned on. Whether the target station is actually reset remotely or not depends on the target station status.</li> <li>• In this FB, stations in other network cannot be set as the target station.</li> <li>• The external device must support SLMP command (Remote Reset (1006H)).</li> <li>• This FB uses UDP communications. The external device must have the same settings.</li> </ul> |

\*1 If 0 (initial value) is stored in the error occurrence time, the error-detected device IP addresses (the third and fourth octets), and the error-detected device IP addresses (the first and second octets), check and take actions using the manuals for the SLMP-compatible device used.

## Operation error

The error code occurred by this FB is the same as the SLMPSND instruction.

## Appendix 1 Instruction Processing Time

The following table lists the processing time of each instruction.

The processing time varies depending on the contents of the source and destination, and the processing optimized according to the program. Assume that the values in the table are reference values.

| Instruction classification |                                  |                                                  | Instruction name | Condition      | Processing time [ns] |
|----------------------------|----------------------------------|--------------------------------------------------|------------------|----------------|----------------------|
| Large classification       | Middle classification            | Small classification                             |                  |                | Minimum              |
| Sequence instruction       | Contact instruction              | —                                                | LD               | Bit device     | 1.25                 |

# CONDITIONS OF USE FOR THE PRODUCT

---

- (1) MELSEC controller system ("the PRODUCT") shall be used in conditions;
- i) where any problem, fault or failure occurring in the PRODUCT, if any, shall not lead to any major or serious accident; and
  - ii) where the backup and fail-safe function are systematically or automatically provided outside of the PRODUCT for the case of any problem, fault or failure occurring in the PRODUCT.
- (2) The PRODUCT has been designed and manufactured for the purpose of being used in general industries. MITSUBISHI ELECTRIC SHALL HAVE NO RESPONSIBILITY OR LIABILITY (INCLUDING, BUT NOT LIMITED TO ANY AND ALL RESPONSIBILITY OR LIABILITY BASED ON CONTRACT, WARRANTY, TORT, PRODUCT LIABILITY) FOR ANY INJURY OR DEATH TO PERSONS OR LOSS OR DAMAGE TO PROPERTY CAUSED BY the PRODUCT THAT ARE OPERATED OR USED IN APPLICATION NOT INTENDED OR EXCLUDED BY INSTRUCTIONS, PRECAUTIONS, OR WARNING CONTAINED IN MITSUBISHI ELECTRIC USER'S, INSTRUCTION AND/OR SAFETY MANUALS, TECHNICAL BULLETINS AND GUIDELINES FOR the PRODUCT.
- ("Prohibited Application")
- Prohibited Applications include, but not limited to, the use of the PRODUCT in;
- Nuclear Power Plants and any other power plants operated by Power companies, and/or any other cases in which the public could be affected if any problem or fault occurs in the PRODUCT.
  - Railway companies or Public service purposes, and/or any other cases in which establishment of a special quality assurance system is required by the Purchaser or End User.
  - Aircraft or Aerospace, Medical applications, Train equipment, transport equipment such as Elevator and Escalator, Incineration and Fuel devices, Vehicles, Manned transportation, Equipment for Recreation and Amusement, and Safety devices, handling of Nuclear or Hazardous Materials or Chemicals, Mining and Drilling, and/or other applications where there is a significant risk of injury to the public or property.
- Notwithstanding the above restrictions, Mitsubishi Electric may in its sole discretion, authorize use of the PRODUCT in one or more of the Prohibited Applications, provided that the usage of the PRODUCT is limited only for the specific applications agreed to by Mitsubishi Electric and provided further that no special quality assurance or fail-safe, redundant or other safety features which exceed the general specifications of the PRODUCTS are required. For details, please contact the Mitsubishi Electric representative in your region.
- (3) Mitsubishi Electric shall have no responsibility or liability for any problems involving controller system trouble and system trouble caused by DoS attacks, unauthorized access, computer viruses, and other cyberattacks.

# WARRANTY

---

Please confirm the following product warranty details before using this product.

## **1. Gratis Warranty Term and Gratis Warranty Range**

If any faults or defects (hereinafter "Failure") found to be the responsibility of Mitsubishi occurs during use of the product within the gratis warranty term, the product shall be repaired at no cost via the sales representative or Mitsubishi Service Company.

However, if repairs are required onsite at domestic or overseas location, expenses to send an engineer will be solely at the customer's discretion. Mitsubishi shall not be held responsible for any re-commissioning, maintenance, or testing on-site that involves replacement of the failed module.

[Gratis Warranty Term]

The gratis warranty term of the product shall be for one year after the date of purchase or delivery to a designated place. Note that after manufacture and shipment from Mitsubishi, the maximum distribution period shall be six (6) months, and the longest gratis warranty term after manufacturing shall be eighteen (18) months. The gratis warranty term of repair parts shall not exceed the gratis warranty term before repairs.

[Gratis Warranty Range]

- (1) The range shall be limited to normal use within the usage state, usage methods and usage environment, etc., which follow the conditions and precautions, etc., given in the instruction manual, user's manual and caution labels on the product.
- (2) Even within the gratis warranty term, repairs shall be charged for in the following cases.
  1. Failure occurring from inappropriate storage or handling, carelessness or negligence by the user. Failure caused by the user's hardware or software design.
  2. Failure caused by unapproved modifications, etc., to the product by the user.
  3. When the Mitsubishi product is assembled into a user's device, Failure that could have been avoided if functions or structures, judged as necessary in the legal safety measures the user's device is subject to or as necessary by industry standards, had been provided.
  4. Failure that could have been avoided if consumable parts (battery, backlight, fuse, etc.) designated in the instruction manual had been correctly serviced or replaced.
  5. Failure caused by external irresistible forces such as fires or abnormal voltages, and Failure caused by force majeure such as earthquakes, lightning, wind and water damage.
  6. Failure caused by reasons unpredictable by scientific technology standards at time of shipment from Mitsubishi.
  7. Any other failure found not to be the responsibility of Mitsubishi or that admitted not to be so by the user.

## **2. Onerous repair term after discontinuation of production**

- (1) Mitsubishi shall accept onerous product repairs for seven (7) years after production of the product is discontinued. Discontinuation of production shall be notified with Mitsubishi Technical Bulletins, etc.
- (2) Product supply (including repair parts) is not available after production is discontinued.

## **3. Overseas service**

Overseas, repairs shall be accepted by Mitsubishi's local overseas FA Center. Note that the repair conditions at each FA Center may differ.

## **4. Exclusion of loss in opportunity and secondary loss from warranty liability**

Regardless of the gratis warranty term, Mitsubishi shall not be liable for compensation to:

- (1) Damages caused by any cause found not to be the responsibility of Mitsubishi.
- (2) Loss in opportunity, lost profits incurred to the user by Failures of Mitsubishi products.
- (3) Special damages and secondary damages whether foreseeable or not, compensation for accidents, and compensation for damages to products other than Mitsubishi products.
- (4) Replacement by the user, maintenance of on-site equipment, start-up test run and other tasks.

## **5. Changes in product specifications**

The specifications given in the catalogs, manuals or technical documents are subject to change without prior notice.
