

Programmable Automation Controllers

# **MELSEC MX Controller**

MELSEC MX Controller MX-F Model  
Programming Manual

---

# SAFETY PRECAUTIONS

---

(Read these precautions before using this product.)

Before using Mitsubishi Electric FA integrated controllers, please read the manuals for the products used and the relevant manuals carefully and pay full attention to safety to handle the products correctly.

Make sure that the end users read this manual and then keep the manual in a safe place for future reference.

# INTRODUCTION

---

Thank you for purchasing the Mitsubishi Electric FA integrated controllers.

This manual describes the instructions and functions/function blocks required for programming.

Before using this product, please read this manual and the relevant manuals carefully and develop familiarity with the functions and performance of the controller to handle the product correctly.

When applying the program examples provided in this manual to an actual system, ensure the applicability and confirm that it will not cause system control problems.

Please make sure that the end users read this manual.

## PART 1 PROGRAMMING OVERVIEW

|                                                                                                         |           |
|---------------------------------------------------------------------------------------------------------|-----------|
| <b>CHAPTER 1 OVERVIEW</b> .....                                                                         | <b>28</b> |
| 1.1 Instruction Configuration .....                                                                     | 28        |
| 1.2 Data Specification Method .....                                                                     | 30        |
| Bit data .....                                                                                          | 33        |
| 16-bit data (word data) .....                                                                           | 34        |
| 32-bit data (double word data) .....                                                                    | 36        |
| Real number data (floating-point data) .....                                                            | 39        |
| String data .....                                                                                       | 42        |
| 1.3 Execution Condition .....                                                                           | 44        |
| 1.4 Precautions on Programming .....                                                                    | 45        |
| Errors common to instructions .....                                                                     | 45        |
| Checking the ranges of instruction runtime devices and labels .....                                     | 45        |
| Operation when a long timer or long retentive timer device is used .....                                | 51        |
| Precautions for using a link device assigned to a synchronized station as an instruction argument ..... | 53        |
| Operations arising when the OUT, SET/RST, and PLS/PLF instructions of the same device are used .....    | 53        |
| Restrictions on using file registers .....                                                              | 59        |
| <b>CHAPTER 2 PROGRAM ORGANIZATION UNITS</b> .....                                                       | <b>60</b> |
| 2.1 Program Blocks .....                                                                                | 61        |
| 2.2 Functions (FUN) .....                                                                               | 62        |
| 2.3 Function Blocks (FB) .....                                                                          | 66        |
| 2.4 Precautions .....                                                                                   | 77        |
| When a function is used .....                                                                           | 77        |
| When a function block is used .....                                                                     | 77        |
| Operations of when the MC/MCR instructions are used to control EN .....                                 | 81        |
| <b>CHAPTER 3 LADDER DIAGRAM</b> .....                                                                   | <b>86</b> |
| 3.1 Configuration .....                                                                                 | 86        |
| Ladder symbols .....                                                                                    | 86        |
| Program execution order .....                                                                           | 87        |
| Precautions for using a function block in ladder diagram .....                                          | 88        |
| 3.2 Inline ST .....                                                                                     | 89        |
| 3.3 Statements and Notes .....                                                                          | 91        |
| <b>CHAPTER 4 STRUCTURED TEXT LANGUAGE</b> .....                                                         | <b>92</b> |
| 4.1 Configuration .....                                                                                 | 93        |
| Delimiter .....                                                                                         | 94        |
| Operators .....                                                                                         | 94        |
| Instruction .....                                                                                       | 95        |

|                          |     |
|--------------------------|-----|
| Control statements ..... | 96  |
| Constants .....          | 106 |
| Labels and devices ..... | 107 |
| Comments .....           | 109 |

## **CHAPTER 5 FBD/LD 110**

|                                           |            |

| <b>9.2 Motion Function Blocks .....</b>         | <b>199</b> |
| <b>9.3 Standard Function Blocks .....</b>       | <b>202</b> |

## CHAPTER 10 NETWORK FUNCTION BLOCK LIST 203

|      |                                    |     |
|------|------------------------------------|-----|
| 10.1 | Function Blocks for Ethernet       | 203 |
| 10.2 | Function Blocks for CC-Link IE TSN | 204 |

## PART 3 SEQUENCE INSTRUCTIONS/ BASIC INSTRUCTIONS

## CHAPTER 11 SEQUENCE INSTRUCTIONS 206

|      |                                                                                       |     |
|------|---------------------------------------------------------------------------------------|-----|
| 11.1 | <b>Contact Instructions</b>                                                           | 206 |
|      | Operation start, series connection, parallel connection                               | 206 |
|      | Pulse operation start, pulse series connection, pulse parallel connection             | 208 |
|      | Pulse NOT operation start, pulse NOT series connection, pulse NOT parallel connection | 211 |
| 11.2 | <b>Association Instructions</b>                                                       | 214 |
|      | Ladder block series/parallel connection                                               | 214 |
|      | Inverting the operation result                                                        | 215 |
|      | Converting the operation result into a pulse                                          | 216 |
|      | Converting the edge relay operation result into a pulse                               | 217 |
| 11.3 | <b>Output Instructions</b>                                                            | 219 |
|      | Out (excluding the timer, counter, and annunciator)                                   | 219 |
|      | Timer                                                                                 | 221 |
|      | Long timer                                                                            | 224 |
|      | Counter                                                                               | 227 |
|      | Long counter                                                                          | 229 |
|      | Annunciator                                                                           | 231 |
|      | Setting devices (excluding annunciator)                                               | 232 |
|      | Resetting devices (excluding annunciator)                                             | 234 |
|      | Setting annunciator                                                                   | 236 |
|      | Resetting annunciator                                                                 | 238 |
|      | Rising edge output                                                                    | 240 |
|      | Falling edge output                                                                   | 242 |
|      | Inverting the bit device output                                                       | 244 |
|      | Converting the direct access output into a pulse                                      | 245 |
| 11.4 | <b>Shift Instructions</b>                                                             | 247 |
|      | Shifting bit devices                                                                  | 247 |
| 11.5 | <b>Master Control Instructions</b>                                                    | 249 |
|      | Setting/resetting a master control                                                    | 249 |
| 11.6 | <b>Termination Instructions</b>                                                       | 253 |
|      | Ending the main routine program                                                       | 253 |
|      | Ending the sequence program                                                           | 254 |

|      | Stopping the sequence program                                                         | 256 |
| 11.8 | <b>No Operation Instruction</b>                                                       | 257 |
|      | No operation (NOPLF)                                                                  | 257 |

## CHAPTER 12 BASIC INSTRUCTIONS 258

|      |                                          |     |
|------|------------------------------------------|-----|
| 12.1 | <b>Comparison Operation Instructions</b> | 258 |
|      | Comparing 16-bit binary data             | 258 |
|      | Comparing 32-bit binary data             | 260 |
|      | Comparing 16-bit binary block data       | 262 |

|             |                                                                |            |
|-------------|----------------------------------------------------------------|------------|
|             | Comparing 32-bit binary block data . . . . .                   | 265        |
| <b>12.2</b> | <b>Arithmetic Operation Instructions . . . . .</b>             | <b>268</b> |
|             | Adding 16-bit binary data . . . . .                            | 268        |
|             | Subtracting 16-bit binary data . . . . .                       | 272        |
|             | Adding 32-bit binary data . . . . .                            | 276        |
|             | Subtracting 32-bit binary data . . . . .                       | 280        |
|             | Multiplying 16-bit binary data . . . . .                       | 284        |
|             | Dividing 16-bit binary data . . . . .                          | 286        |
|             | Multiplying 32-bit binary data . . . . .                       | 288        |
|             | Dividing 32-bit binary data . . . . .                          | 290        |
|             | Adding BCD 4-digit data . . . . .                              | 292        |
|             | Subtracting BCD 4-digit data . . . . .                         | 295        |
|             | Adding BCD 8-digit data . . . . .                              | 298        |
|             | Subtracting BCD 8-digit data . . . . .                         | 301        |
|             | Multiplying BCD 4-digit data . . . . .                         | 305        |
|             | Dividing BCD 4-digit data . . . . .                            | 307        |
|             | Multiplying BCD 8-digit data . . . . .                         | 309        |
|             | Dividing BCD 8-digit data . . . . .                            | 311        |
|             | Adding 16-bit binary block data . . . . .                      | 313        |
|             | Subtracting 16-bit binary block data . . . . .                 | 315        |
|             | Adding 32-bit binary block data . . . . .                      | 317        |
|             | Subtracting 32-bit binary block data . . . . .                 | 320        |
|             | Incrementing 16-bit binary data . . . . .                      | 323        |
|             | Decrementing 16-bit binary data . . . . .                      | 324        |
|             | Incrementing 32-bit binary data . . . . .                      | 325        |
|             | Decrementing 32-bit binary data . . . . .                      | 326        |
| <b>12.3</b> | <b>Logical Operation Instructions . . . . .</b>                | <b>327</b> |
|             | Performing an AND operation on 16-bit data . . . . .           | 327        |
|             | Performing an AND operation on 32-bit data . . . . .           | 330        |
|             | Performing an AND operation on 16-bit block data . . . . .     | 334        |
|             | Performing an OR operation on 16-bit data . . . . .            | 336        |
|             | Performing an OR operation on 32-bit data . . . . .            | 339        |
|             | Performing an OR operation on 16-bit block data . . . . .      | 343        |
|             | Performing an XOR operation on 16-bit data . . . . .           | 345        |
|             | Performing an XOR operation on 32-bit data . . . . .           | 348        |
|             | Performing an XOR operation on 16-bit block data . . . . .     | 352        |
|             | Performing an XNOR operation on 16-bit data . . . . .          | 354        |
|             | Performing an XNOR operation on 32-bit data . . . . .          | 357        |
|             | Performing an XNOR operation on 16-bit block data . . . . .    | 361        |
| <b>12.4</b> | <b>Bit Processing Instructions . . . . .</b>                   | <b>363</b> |
|             | Setting a bit in the word device . . . . .                     | 363        |
|             | Resetting a bit in the word device . . . . .                   | 365        |
|             | Performing a 16-bit test . . . . .                             | 366        |
|             | Performing a 32-bit test . . . . .                             | 368        |
|             | Batch-resetting bit devices . . . . .                          | 370        |
| <b>12.5</b> | <b>Shift Instructions . . . . .</b>                            | <b>372</b> |
|             | Shifting 16-bit binary data to the right by n bit(s) . . . . . | 372        |
|             | Shifting 16-bit binary data to the left by n bit(s) . . . . .  | 374        |
|             | Shifting n-bit data to the right by one bit . . . . .          | 376        |
|             | Shifting n-bit data to the left by one bit . . . . .           | 378        |
|             | Shifting n-word data to the right by one word . . . . .        | 380        |

|                                                                                  |            |
|----------------------------------------------------------------------------------|------------|
| Shifting n-word data to the left by one word . . . . .                           | 382        |
| Shifting n-bit data to the right by n bit(s) . . . . .                           | 384        |
| Shifting n-bit data to the left by n bit(s) . . . . .                            | 386        |
| Shifting n-word data to the right by n word(s) . . . . .                         | 388        |
| Shifting n-word data to the left by n word(s) . . . . .                          | 390        |
| <b>12.6 Data Conversion Instructions . . . . .</b>                               | <b>392</b> |
| Converting binary data to BCD 4-digit data . . . . .                             | 392        |
| Converting binary data to BCD 8-digit data . . . . .                             | 394        |
| Converting BCD 4-digit data to 16-bit binary data . . . . .                      | 396        |
| Converting BCD 8-digit data to 32-bit binary data . . . . .                      | 398        |

| <b>CHAPTER 13 PROGRAM CONTROL . . . . .</b>                                                     | <b>534</b> |
| <b>13.1 Program Branch Instructions. . . . .</b>                                                | <b>534</b> |
| Pointer branch . . . . .                                                                        | 534        |
| Jumping to END . . . . .                                                                        | 537        |
| <b>13.2 Program Execution Control Instructions . . . . .</b>                                    | <b>538</b> |
| Disabling/enabling interrupt programs. . . . .                                                  | 538        |
| Disabling interrupt programs with specified priority or lower . . . . .                         | 542        |
| Interrupt program mask . . . . .                                                                | 547        |
| Disabling/enabling the specified interrupt pointer . . . . .                                    | 549        |
| Returning from the interrupt program . . . . .                                                  | 551        |
| Resetting the watchdog timer . . . . .                                                          | 552        |
| <b>13.3 Structure Creation Instructions . . . . .</b>                                           | <b>553</b> |
| Performing the FOR to NEXT instruction loop. . . . .                                            | 553        |
| Forcibly terminating the FOR to NEXT instruction loop. . . . .                                  | 556        |
| Calling a subroutine program . . . . .                                                          | 558        |
| Returning from the subroutine program called . . . . .                                          | 564        |
| Calling a subroutine program and turning the output off . . . . .                               | 565        |
| Calling a subroutine program in the specified program file . . . . .                            | 571        |
| Calling a subroutine program in the specified program file and turning the output off . . . . . | 578        |
| Calling a subroutine program . . . . .                                                          | 583        |

|                                                        |            |
|--------------------------------------------------------|------------|
| <b>CHAPTER 14 DATA PROCESSING</b>                      | <b>588</b> |
| <b>14.1 Rotation Instructions</b>                      | <b>588</b> |
| Rotating 16-bit binary data to the right               | 588        |
| Rotating 16-bit binary data to the left                | 591        |
| Rotating 32-bit binary data to the right               | 594        |
| Rotating 32-bit binary data to the left                | 596        |
| <b>14.2 Data Table Operation Instructions</b>          | <b>598</b> |
| Reading the oldest data from the data table            | 598        |
| Reading the newest data from the data table            | 600        |
| Writing data to the data table                         | 602        |
| Inserting data to the data table                       | 604        |
| Deleting data from data table                          | 606        |
| <b>14.3 Reading/Writing Data Instructions</b>          | <b>608</b> |
| Reading data from the data memory                      | 609        |
| Writing data to the data memory                        | 611        |
| <b>14.4 File Operation Instructions</b>                | <b>614</b> |
| Reading data from the specified file                   | 614        |
| Writing data to the specified file                     | 630        |
| Deleting the specified file                            | 644        |
| Copying the specified file                             | 647        |
| Moving the specified file                              | 652        |
| Renaming the specified file                            | 657        |
| Acquiring the status of the specified file             | 660        |
| Error codes generated for file operation instructions  | 663        |
| <b>14.5 Data Control Instructions</b>                  | <b>664</b> |
| Upper and lower limit control of 16-bit binary data    | 664        |
| Upper and lower limit control of 32-bit binary data    | 666        |
| Dead band control of 16-bit binary data                | 668        |
| Dead band control of 32-bit binary data                | 670        |
| Zone control of 16-bit binary data                     | 672        |
| Zone control of 32-bit binary data                     | 674        |
| Scaling 16-bit binary data (point coordinates)         | 676        |
| Scaling 32-bit binary data (point coordinates)         | 679        |
| Scaling 16-bit binary data (XY coordinates)            | 682        |
| Scaling 32-bit binary data (XY coordinates)            | 684        |
| <b>14.6 Data Processing Instructions</b>               | <b>686</b> |
| Searching 16-bit binary data                           | 686        |
| Searching 32-bit binary data                           | 688        |
| Searching 16-bit binary data (minimum, match, maximum) | 690        |
| Searching 32-bit binary data (minimum, match, maximum) | 692        |
| Checking 16-bit binary data                            | 694        |
| Checking 32-bit binary data                            | 695        |
| Searching the maximum value of 16-bit binary data      | 696        |
| Searching the maximum value of 32-bit binary data      | 698        |
| Searching the minimum value of 16-bit binary data      | 700        |
| Searching the minimum value of 32-bit binary data      | 702        |
| Sorting 16-bit binary data                             | 704        |
| Sorting 32-bit binary data                             | 706        |
| Adding 16-bit binary data                              | 708        |
| Adding 32-bit binary data                              | 710        |

|                                                            |     |
|------------------------------------------------------------|-----|
| Calculating the mean value of 16-bit binary data . . . . . | 712 |
| Calculating the mean value of 32-bit binary data . . . . . | 714 |
| Calculating the square root of 16-bit binary data. . . . . | 716 |
| Calculating the square root of 32-bit binary data. . . . . | 717 |
| CRC operation. . . . .                                     | 718 |

## **CHAPTER 15 DEBUGGING AND FAILURE DIAGNOSTIC** **720**

---

|                                                                    |            |
|--------------------------------------------------------------------|------------|
| <b>15.1 Debugging and Failure Diagnostic Instructions. . . . .</b> | <b>720</b> |
| Resetting the error display and the annunciator display . . . . .  | 720        |

---

## **CHAPTER 16 STRING PROCESSING** **722**

---

|                                                                                   |            |
|-----------------------------------------------------------------------------------|------------|
| <b>16.1 String Processing Instructions . . . . .</b>                              | <b>722</b> |
| Comparing string data . . . . .                                                   | 722        |
| Concatenating string data . . . . .                                               | 725        |
| Transferring string data . . . . .                                                | 729        |
| Transferring Unicode string data . . . . .                                        | 731        |
| Converting 16-bit binary data to decimal ASCII. . . . .                           | 733        |
| Converting 32-bit binary data to decimal ASCII. . . . .                           | 737        |
| Converting 16-bit binary data to hexadecimal ASCII. . . . .                       | 742        |
| Converting 32-bit binary data to hexadecimal ASCII. . . . .                       | 746        |
| Converting 16-bit binary data to string data. . . . .                             | 750        |
| Converting 32-bit binary data to string data. . . . .                             | 753        |
| Converting BCD 4-digit data to decimal ASCII code . . . . .                       | 756        |
| Converting BCD 8-digit data to decimal ASCII code . . . . .                       | 760        |
| Converting single-precision real number to string data. . . . .                   | 765        |
| Converting hexadecimal binary data to hexadecimal ASCII code. . . . .             | 770        |
| Converting and concatenating multiple data strings . . . . .                      | 772        |
| Converting Unicode string to Shift JIS string . . . . .                           | 789        |
| Converting Shift JIS string to Unicode string (without byte order mark) . . . . . | 791        |
| Converting shift JIS string to Unicode (with byte order mark) . . . . .           | 793        |
| Detecting a string length . . . . .                                               | 795        |
| Extracting string data from the right. . . . .                                    | 797        |
| Extracting string data from the left. . . . .                                     | 799        |
| Extracting the specified string data . . . . .                                    | 801        |
| Replacing the specified string data . . . . .                                     | 803        |
| Searching string data. . . . .                                                    | 806        |
| Inserting string data. . . . .                                                    | 808        |
| Deleting string data . . . . .                                                    | 810        |

---

## **CHAPTER 17 REAL VALUE PROCESSING** **812**

---

|                                                     |            |
|-----------------------------------------------------|------------|
| <b>17.1 Floating-point Instruction. . . . .</b>     | <b>812</b> |
| Comparing single-precision real numbers. . . . .    | 812        |
| Comparing double-precision real numbers . . . . .   | 814        |
| Adding single-precision real numbers . . . . .      | 817        |
| Subtracting single-precision real numbers . . . . . | 821        |
| Adding double-precision real numbers . . . . .      | 825        |
| Subtracting double-precision real numbers. . . . .  | 829        |
| Multiplying single-precision real numbers . . . . . | 833        |
| Dividing single-precision real numbers . . . . .    | 835        |
| Multiplying double-precision real numbers . . . . . | 837        |

|                                                                                   |     |
|-----------------------------------------------------------------------------------|-----|
| Dividing double-precision real numbers . . . . .                                  | 839 |
| Converting 16-bit signed binary data to single-precision real number. . . . .     | 841 |
| Converting 16-bit unsigned binary data to single-precision real number. . . . .   | 842 |
| Converting 32-bit signed binary data to single-precision real number. . . . .     | 843 |
| Converting 32-bit unsigned binary data to single-precision real number. . . . .   | 845 |
| Converting double-precision real number to single-precision real number . . . . . | 847 |
| Converting 16-bit signed binary data to double-precision real number . . . . .    | 849 |
| Converting 16-bit unsigned binary data to double-precision real number . . . . .  | 850 |
| Converting 32-bit signed binary data to double-precision real number . . . . .    | 851 |
| Converting 32-bit unsigned binary data to double-precision real number . . . . .  | 852 |
| Converting single-precision real number to double-precision real number . . . . . | 853 |
| Converting string data to single-precision real number . . . . .                  | 855 |
| Converting BCD format data to single-precision real number . . . . .              | 860 |
| Inverting the sign of single-precision real number . . . . .                      | 862 |
| Inverting the sign of double-precision real number . . . . .                      | 863 |
| Transferring single-precision real number . . . . .                               | 864 |
| Transferring double-precision real number . . . . .                               | 865 |
| Calculating the sine of single-precision real number . . . . .                    | 866 |
| Calculating the cosine of single-precision real number . . . . .                  | 868 |
| Calculating the tangent of single-precision real number . . . . .                 | 870 |
| Calculating the arc sine of single-precision real number . . . . .                | 872 |
| Calculating the arc cosine of single-precision real number . . . . .              | 874 |
| Calculating the arc tangent of single-precision real number . . . . .             | 876 |
| Calculating the sine of double-precision real number . . . . .                    | 878 |
| Calculating the cosine of double-precision real number . . . . .                  | 880 |
| Calculating the tangent of double-precision real number . . . . .                 | 882 |
| Calculating the arc sine of double-precision real number . . . . .                | 884 |
| Calculating the arc cosine of double-precision real number . . . . .              | 886 |
| Calculating the arc tangent of double-precision real number . . . . .             | 888 |
| Calculating the sine of BCD data . . . . .                                        | 890 |
| Calculating the cosine of BCD data . . . . .                                      | 892 |
| Calculating the tangent of BCD data . . . . .                                     | 894 |
| Calculating the arc sine of BCD data . . . . .                                    | 896 |
| Calculating the arc cosine of BCD data . . . . .                                  | 898 |
| Calculating the arc tangent of BCD data . . . . .                                 | 900 |
| Converting single-precision real number angle to radian . . . . .                 | 902 |
| Converting single-precision real number radian to angle . . . . .                 | 904 |
| Converting double-precision real number angle to radian . . . . .                 | 906 |
| Converting double-precision real number radian to angle . . . . .                 | 908 |
| Calculating the square root of single-precision real number . . . . .             | 910 |
| Calculating the square root of double-precision real number . . . . .             | 912 |
| Calculating the exponent of single-precision real number . . . . .                | 914 |
| Calculating the exponent of double-precision real number . . . . .                | 916 |
| Calculating the natural logarithm of single-precision real number . . . . .       | 918 |
| Calculating the natural logarithm of double-precision real number . . . . .       | 920 |
| Calculating the square root of BCD 4-digit data . . . . .                         | 922 |
| Calculating the square root of BCD 8-digit data . . . . .                         | 924 |
| Calculating the exponentiation of single-precision real number . . . . .          | 926 |
| Calculating the exponentiation of double-precision real number . . . . .          | 928 |
| Calculating the common logarithm of single-precision real number . . . . .        | 930 |
| Calculating the common logarithm of double-precision real number . . . . .        | 932 |

|                                                                       |     |
|-----------------------------------------------------------------------|-----|
| Searching the maximum value of single-precision real number . . . . . | 934 |
| Searching the maximum value of double-precision real number. . . . .  | 936 |
| Searching the minimum value of single-precision real number . . . . . | 938 |
| Searching the minimum value of double-precision real number . . . . . | 940 |

## **CHAPTER 18 RANDOM NUMBER** **942**

---

|                                                  |            |
|--------------------------------------------------|------------|
| <b>18.1 Random Number Instructions . . . . .</b> | <b>942</b> |
| Generating random number . . . . .               | 942        |
| Changing random sequence . . . . .               | 943        |

---

## **CHAPTER 19 DEVICE OPERATION** **944**

---

|                                                                                    |            |
|------------------------------------------------------------------------------------|------------|
| <b>19.1 Index Register Instructions . . . . .</b>                                  | <b>944</b> |
| Saving all data of the index register . . . . .                                    | 944        |
| Returning all data of the index register . . . . .                                 | 947        |
| Saving the selected data of the index register and long index register . . . . .   | 948        |
| Returning the selected data of the index register and long index register. . . . . | 952        |
| <b>19.2 File Register Operation Instructions . . . . .</b>                         | <b>954</b> |
| Switching the file register block number . . . . .                                 | 954        |
| <b>19.3 File Register Read/Write Instructions . . . . .</b>                        | <b>956</b> |
| Reading 1-byte data from the file register . . . . .                               | 956        |
| Writing 1-byte data to the file register . . . . .                                 | 958        |
| <b>19.4 Indirect Address Read Instructions . . . . .</b>                           | <b>961</b> |
| Reading the indirect address. . . . .                                              | 961        |

---

## **CHAPTER 20 TIMER, COUNTER** **963**

---

|                                                                 |            |
|-----------------------------------------------------------------|------------|
| <b>20.1 Special Counter Instructions . . . . .</b>              | <b>963</b> |
| Counting up or down the current value (1-phase input) . . . . . | 963        |
| Counting up or down the current value (2-phase input) . . . . . | 965        |
| <b>20.2 Special Timer Instructions . . . . .</b>                | <b>967</b> |
| Teaching timer . . . . .                                        | 967        |
| Special function timer . . . . .                                | 969        |

---

## **CHAPTER 21 CLOCK** **972**

---

|                                                                     |             |
|---------------------------------------------------------------------|-------------|
| <b>21.1 Clock Instructions . . . . .</b>                            | <b>972</b>  |
| Reading clock data . . . . .                                        | 972         |
| Writing clock data . . . . .                                        | 974         |
| Adding clock data . . . . .                                         | 976         |
| Subtracting clock data . . . . .                                    | 978         |
| Converting time data from hour/minute/second to second . . . . .    | 980         |
| Converting time data from second to hour/minute/second . . . . .    | 982         |
| Converting date and time data from date and time to second. . . . . | 984         |
| Converting date and time data from second to date and time. . . . . | 986         |
| Comparing date data . . . . .                                       | 988         |
| Comparing time data . . . . .                                       | 992         |
| Outputting a comparison result of time data . . . . .               | 995         |
| Reading expansion clock data. . . . .                               | 997         |
| Adding expansion clock data. . . . .                                | 999         |
| Subtracting expansion clock data . . . . .                          | 1001        |
| <b>21.2 Timing Check Instructions . . . . .</b>                     | <b>1003</b> |
| Generating timing pulses. . . . .                                   | 1003        |

|                                                                                 |             |
|---------------------------------------------------------------------------------|-------------|
| Measuring time of the specified data . . . . .                                  | 1005        |
| <b>CHAPTER 22 MODULE ACCESS</b>                                                 | <b>1007</b> |
| <b>22.1 Module Access Instructions . . . . .</b>                                | <b>1007</b> |
| Performing I/O refresh . . . . .                                                | 1007        |
| Reading 1-word/2-word data from another module (16-bit specification) . . . . . | 1009        |
| Writing 1-word/2-word data to a module (16-bit specification) . . . . .         | 1012        |
| Reading 1-word/2-word data from another module (32-bit specification) . . . . . | 1017        |
| Writing 1-word/2-word data to a module (32-bit specification) . . . . .         | 1021        |
| Reading module specific information . . . . .                                   | 1025        |
| <b>CHAPTER 23 PID OPERATION INSTRUCTION</b>                                     | <b>1029</b> |
| <b>23.1 Overview . . . . .</b>                                                  | <b>1029</b> |
| Control data . . . . .                                                          | 1031        |
| Auto tuning . . . . .                                                           | 1039        |
| <b>23.2 PID Operation Instruction . . . . .</b>                                 | <b>1041</b> |
| <b>CHAPTER 24 PID CONTROL INSTRUCTIONS</b>                                      | <b>1045</b> |
| <b>24.1 Overview . . . . .</b>                                                  | <b>1045</b> |
| Operation method . . . . .                                                      | 1045        |
| PID control procedure . . . . .                                                 | 1046        |
| Helpful functions . . . . .                                                     | 1052        |
| <b>24.2 PID Control Instructions (Inexact Differential) . . . . .</b>           | <b>1054</b> |
| Registering the PID control data to the controller . . . . .                    | 1056        |
| Performing PID operation . . . . .                                              | 1059        |
| Stopping the operation of specified loop number . . . . .                       | 1062        |
| Starting the operation of specified loop number . . . . .                       | 1063        |
| Changing the parameters of specified loop number . . . . .                      | 1064        |
| <b>24.3 PID Control Instructions (Exact Differential) . . . . .</b>             | <b>1066</b> |
| Registering the PID control data to the controller . . . . .                    | 1068        |
| Performing PID operation . . . . .                                              | 1070        |
| Stopping the operation of specified loop number . . . . .                       | 1073        |
| Starting the operation of specified loop number . . . . .                       | 1074        |
| Changing the parameters of specified loop number . . . . .                      | 1075        |
| <b>CHAPTER 25 HIGH-SPEED I/O CONTROL INSTRUCTIONS</b>                           | <b>1077</b> |
| <b>25.1 Start/Stop of High-Speed I/O . . . . .</b>                              | <b>1077</b> |
| Start/stop of the 16-bit data high-speed I/O function . . . . .                 | 1077        |
| Start/stop of the 32-bit data high-speed I/O function . . . . .                 | 1080        |
| <b>CHAPTER 26 DEDICATED INSTRUCTIONS (POSITIONING FUNCTION)</b>                 | <b>1083</b> |
| <b>26.1 Mechanical OPR . . . . .</b>                                            | <b>1083</b> |
| <b>26.2 Interrupt 1-speed Positioning . . . . .</b>                             | <b>1090</b> |
| <b>26.3 Variable Speed Operation . . . . .</b>                                  | <b>1096</b> |
| <b>26.4 1-speed Positioning (Relative) . . . . .</b>                            | <b>1101</b> |
| <b>26.5 1-speed Positioning (Absolute) . . . . .</b>                            | <b>1106</b> |
| <b>26.6 Table Operation (Multiple Tables) . . . . .</b>                         | <b>1111</b> |

## CHAPTER 32 SINGLE VARIABLE FUNCTIONS 1316

---

|       |                                         |      |
|-------|-----------------------------------------|------|
| 32.1  | Calculating the Absolute Value .....    | 1316 |
| 32.2  | Calculating the Square Root .....       | 1318 |
| 32.3  | Calculating the Natural Logarithm ..... | 1319 |
| 32.4  | Calculating the Common Logarithm .....  | 1320 |
| 32.5  | Calculating the Exponent .....          | 1322 |
| 32.6  | Calculating the Sine .....              | 1323 |
| 32.7  | Calculating the Cosine .....            | 1324 |
| 32.8  | Calculating the Tangent .....           | 1325 |
| 32.9  | Calculating the Arc Sine .....          | 1326 |
| 32.10 | Calculating the Arc Cosine .....        | 1327 |
| 32.11 | Calculating the Arc Tangent .....       | 1328 |

---

## CHAPTER 33 ARITHMETIC OPERATION FUNCTIONS 1329

---

|      |                                   |      |
|------|-----------------------------------|------|
| 33.1 | Addition .....                    | 1329 |
| 33.2 | Multiplication .....              | 1332 |
| 33.3 | Subtraction .....                 | 1335 |
| 33.4 | Division .....                    | 1338 |
| 33.5 | Remainder .....                   | 1340 |
| 33.6 | Exponentiation .....              | 1342 |
| 33.7 | Assignment (Move Operation) ..... | 1344 |

---

## CHAPTER 34 BIT SHIFT FUNCTIONS 1346

---

|      |                                              |      |
|------|----------------------------------------------|------|
| 34.1 | Shifting Data to the Left by n Bit(s) .....  | 1346 |
| 34.2 | Shifting Data to the Right by n Bit(s) ..... | 1348 |
| 34.3 | Rotating Data to the Left by n Bit(s) .....  | 1350 |
| 34.4 | Rotating Data to the Right by n Bit(s) ..... | 1352 |

---

## CHAPTER 35 BOOLEAN FUNCTIONS 1354

---

|      |                                                      |      |
|------|------------------------------------------------------|------|
| 35.1 | AND Operation, OR Operation, and XOR Operation ..... | 1354 |
| 35.2 | NOT Operation .....                                  | 1357 |

---

## CHAPTER 36 SELECTION FUNCTIONS 1358

---

|      |                                           |      |
|------|-------------------------------------------|------|
| 36.1 | Selecting a Value .....                   | 1358 |
| 36.2 | Selecting the Maximum/Minimum Value ..... | 1360 |
| 36.3 | Controlling the Upper/Lower Limit .....   | 1362 |

|                                                  |                                                              |             |
|--------------------------------------------------|--------------------------------------------------------------|-------------|
| 36.4                                             | Multiplexer .....                                            | 1365        |
| <b>CHAPTER 37 COMPARISON FUNCTIONS</b>           |                                                              | <b>1367</b> |
| 37.1                                             | Comparing Data .....                                         | 1367        |
| 37.2                                             | Comparing Data .....                                         | 1369        |
| <b>CHAPTER 38 STRING FUNCTIONS</b>               |                                                              | <b>1371</b> |
| 38.1                                             | Detecting a String Length .....                              | 1371        |
| 38.2                                             | Extracting String Data From the Left/Right .....             | 1373        |
| 38.3                                             | Extracting String Data .....                                 | 1376        |
| 38.4                                             | Concatenating String Data .....                              | 1378        |
| 38.5                                             | Inserting String Data .....                                  | 1380        |
| 38.6                                             | Deleting String Data .....                                   | 1382        |
| 38.7                                             | Replacing String Data .....                                  | 1384        |
| 38.8                                             | Searching String Data .....                                  | 1387        |
| <b>CHAPTER 39 TIME DATA TYPE FUNCTIONS</b>       |                                                              | <b>1389</b> |

# TERMS

Unless otherwise specified, this manual uses the following terms.

| Term                                  | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Actual position                       | A position obtained by rounding a position address returned by a device with a ring counter. It is affected by a current position change.                                                                                                                                                                                                                                                    |
| Actual velocity                       | A value obtained by converting the actual value received from the device on the real axis to the unit of the axis                                                                                                                                                                                                                                                                            |
| Axes group variable                   | An AXES_GROUP type variable instance including parameters and data related to the axes group                                                                                                                                                                                                                                                                                                 |
| Axis                                  | A target to perform the motion control                                                                                                                                                                                                                                                                                                                                                       |
| Axis variable                         | An AXIS_* type variable instance including parameters and data related to the axis                                                                                                                                                                                                                                                                                                           |
| Axis warning                          | An error or a warning related to an axis                                                                                                                                                                                                                                                                                                                                                     |
| Basic core                            | A core that executes a program                                                                                                                                                                                                                                                                                                                                                               |
| Buffer memory                         | A memory to store data such as setting values and monitored values. The data include setting values and monitored values of the network function.                                                                                                                                                                                                                                            |
| Buffering                             | Standby status of a motion control FB when multiple start is performed                                                                                                                                                                                                                                                                                                                       |
| Buffering FB                          | A motion control FB that is in a pending status (Busy is TRUE) when multiple start is performed                                                                                                                                                                                                                                                                                              |
| Cam table                             | An operation profile data used for cam control<br>(Ex.) Operation profile data of cam data format or operation profile data of cam data format for rotary cutter                                                                                                                                                                                                                             |
| CC-Link IE TSN Class                  | A group of devices and switching hubs compatible with CC-Link IE TSN, ranked according to the functions and performance by the CC-Link Partner Association.<br>For CC-Link IE TSN Class, refer to the CC-Link IE TSN Installation Manual (BAP-C3007ENG-001) published by the CC-Link Partner Association.                                                                                    |
| CC-Link IE TSN function part          | A part of the controller used for CC-Link IE TSN communications                                                                                                                                                                                                                                                                                                                              |
| CC-Link IE TSN Protocol version 1.0   | This protocol is used to perform communications by using the time sharing method defined by IEEE 802.1AS or IEEE 1588 for time synchronization.                                                                                                                                                                                                                                              |
| CC-Link IE TSN Protocol version 2.0   | This protocol is used to perform communications by using the time sharing method defined by IEEE 802.1AS and time-managed polling method for time synchronization.<br>Supporting this protocol version mitigates restrictions when "Mixture of CC-Link IE TSN Class B/A or CC-Link IE TSN Class A Only" is set in the system configuration, and increases the number of connectable devices. |
| Commanded position                    | A command position address that is specified in the motion FB                                                                                                                                                                                                                                                                                                                                |
| Commanded velocity                    | Velocity that is specified in the motion FB                                                                                                                                                                                                                                                                                                                                                  |
| Continuous update                     | Continuous reflection of input values to the control while the ContinuousUpdate input of the motion control FB is TRUE                                                                                                                                                                                                                                                                       |
| Core                                  | An operation circuit of the controller. The controller has multiple cores.                                                                                                                                                                                                                                                                                                                   |
| CPU function part                     | A part of the controller used for sequence control and Ethernet communications                                                                                                                                                                                                                                                                                                               |
| CPU Module Logging Configuration Tool | Software to configure data logging settings and to manage collected data                                                                                                                                                                                                                                                                                                                     |
| Cumulative current position           | A command position address that is not rounded by the ring counter. It is affected by a current position change.                                                                                                                                                                                                                                                                             |
| Cyclic data transfer processing       | Processing of a cyclic transmission from its start to finish, performed by all the stations on a single network. The processing is performed asynchronously with the sequence scan of the controller.<br>The cyclic data transfer processing time varies depending on data volume and the number of transient transmission requests.                                                         |
| Dedicated instruction                 | An instruction that simplifies programming for using functions of intelligent function modules                                                                                                                                                                                                                                                                                               |
| Device                                | A memory of the controller to store data. Devices such as X, Y, M, and D are provided depending on the intended use.                                                                                                                                                                                                                                                                         |
| Device station                        | A station other than a master station: a local station, a remote station                                                                                                                                                                                                                                                                                                                     |
| Disconnection                         | A process of stopping data link for relevant stations if a data link error occurs                                                                                                                                                                                                                                                                                                            |
| Extension core                        | A core to which functions to be executed can be assigned                                                                                                                                                                                                                                                                                                                                     |
| External signal high-accuracy input   | An input signal linked with the signal detection time of the device station                                                                                                                                                                                                                                                                                                                  |
| FB instance                           | A function block that is inserted to a sequence program                                                                                                                                                                                                                                                                                                                                      |
| First point of cam table              | The meaning is different depending on the interpolation method specification for the cam data<br>• Section interpolation or spline interpolation: Point of Table No. 1<br>• Linear interpolation: Point of No. 1                                                                                                                                                                             |
| General-purpose hub                   | A CC-Link IE TSN Class A switching hub authorized by CC-Link Partner Association                                                                                                                                                                                                                                                                                                             |
| Global label                          | A label that is valid for all the program data when multiple program data are created in the project.<br>There are two types of global label: a module specific label (module label), which is generated automatically by GX Works3, and an optional label, which can be created for any specified device.                                                                                   |
| Grandmaster                           | A source device or station to synchronize clocks in the time synchronization via PTP (Precision Time Protocol)                                                                                                                                                                                                                                                                               |
| GX LogViewer                          | Software to display data collected by data logging                                                                                                                                                                                                                                                                                                                                           |

| Term                                    | Description                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GX Works3                               | The product name of the software package for the MELSEC programmable controllers                                                                                                                                                                                                                                                                            |
| Input variable                          | An input argument of FB                                                                                                                                                                                                                                                                                                                                     |
| Intelligent function module             | A module that has functions other than input and output, such as an A/D converter module and D/A converter module                                                                                                                                                                                                                                           |
| iQSS                                    | iQ Sensor Solution. Cooperation of sensors, programmable controllers, HMI (Human Machine Interface), and engineering tool to facilitate the start-up or maintenance of sensors. (iQ Sensor Solution Reference Manual)                                                                                                                                       |
| Jerk                                    | Chronological change rate of acceleration or deceleration                                                                                                                                                                                                                                                                                                   |
| Label                                   | A variable consisting of a specified string used in I/O data or internal processing                                                                                                                                                                                                                                                                         |
| Link device                             | A device (RX, RY, RWr, or RWw) in the CC-Link IE TSN function part or a network module                                                                                                                                                                                                                                                                      |
| Machine feed value                      | A command position address that is not rounded by the ring counter. It is based on the home position, and it is not affected by a current position change.                                                                                                                                                                                                  |
| Master axis (input) absolute coordinate | Another term for the Master axis absolute coordinate (MasterAbsolute) for input variables of MC_CamTableSelect (Cam Table Selection)                                                                                                                                                                                                                        |
| Master station                          | A station that controls the entire network. This station can perform cyclic transmission and transient transmission with all stations. Only one master station can be used in a network.                                                                                                                                                                    |
| Module label                            | A label that represents one of memory areas (I/O signals and buffer memory areas) specific to each module in a given string.<br>For the module used, GX Works3 automatically generates this label, which can be used as a global label.                                                                                                                     |
| Motion control FB                       | An FB that is related to motion control. Its name starts with MC_ or MCv_.                                                                                                                                                                                                                                                                                  |
| Motion FB                               | A motion control FB that takes an axis or an axes group for the argument and changes the axis status or the axes group status when executed                                                                                                                                                                                                                 |
| Motion function part                    | A part of the controller used for motion control                                                                                                                                                                                                                                                                                                            |
| MR Configurator2                        | A product name of the servo setup software                                                                                                                                                                                                                                                                                                                  |
| Multiple axes interpolation control     | Control in which multiple axes work together such as linear interpolation and circular interpolation. Axes to be cooperated are specified in an axes group.                                                                                                                                                                                                 |
| Multiple start                          | Executing another motion control FB to the same axis to which the other motion control FB is being executed                                                                                                                                                                                                                                                 |
| Object                                  | Data of a device compatible with CANopen                                                                                                                                                                                                                                                                                                                    |
| Output variable                         | An output argument of FB                                                                                                                                                                                                                                                                                                                                    |
| POU                                     | A unit that configures a program. Units are categorized and provided in accordance with functions. A program that is composed of POUs (program organization units) allows the lower-layer processing, when the program is multi-layered, to be divided into several units by processing and function, enabling the creation of programs based on each unit. |
| Predefined protocol support function    | A function of GX Works3. This function sets protocols appropriate to each external device and reads/writes protocol setting data.                                                                                                                                                                                                                           |
| Program block                           | A group of POUs that configure a program                                                                                                                                                                                                                                                                                                                    |
| Real axis                               | An axis that is linked with a device on the network                                                                                                                                                                                                                                                                                                         |
| Real drive axis                         | An axis that is linked with a CC-Link IE TSN compatible device that supports csp/csv/cst mode (sequential command) of the CiA402 drive profile                                                                                                                                                                                                              |
| Real encoder axis                       | An axis that generates a commanded position from the current position of the encoder connected with a device. It is used for the master axis of the single axis synchronous control.                                                                                                                                                                        |
| Reconnection                            | A process of restarting data link for relevant stations when the faulty station recovers from an error                                                                                                                                                                                                                                                      |
| Relay station                           | A station that relays data link to other station with mounting more than one network modules on one programmable controller.                                                                                                                                                                                                                                |
| Remote station                          | A station that exchanges I/O signals (bit data) and I/O data (word data) with another station by cyclic transmission. This station can perform transient transmission.                                                                                                                                                                                      |
| Reserved address                        | An IP address reserved for special purposes, defined by RFC 6890. This IP address cannot be used when the programmable controller is connected via the global IP network.                                                                                                                                                                                   |
| Routing                                 | A process of selecting paths for communication with other networks. There are two types of routing: dynamic routing that auto-selects the communication routes, and static routing where communication routes are arbitrarily set.                                                                                                                          |
| RWr                                     | A remote register of the link device. Word data (16-bit data) input from a device station to the master station.                                                                                                                                                                                                                                            |
| RWw                                     | A remote register of the link device. Word data (16-bit data) output from the master station to a device station.                                                                                                                                                                                                                                           |
| RX                                      | Remote input of the link device. Bit data input from a device station to the master station.                                                                                                                                                                                                                                                                |
| RY                                      | Remote output of the link device. Bit data output from the master station to a device station.                                                                                                                                                                                                                                                              |
| SB                                      | An abbreviation for a link special relay. Bit data that indicates the operating status and data link status of a module on CC-Link IE.                                                                                                                                                                                                                      |
| Set position                            | A commanded position address rounded by the ring counter. It is affected by a current position change.                                                                                                                                                                                                                                                      |
| Set velocity                            | The current control value that is generated by motion operation                                                                                                                                                                                                                                                                                             |

| Term                                    | Description                                                                                                                                                                                                                                                  |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signal flow                             | The execution status that the last time an operation of a program or an FB is executed in each step.                                                                                                                                                         |
| Single axis synchronization             | A control to output the position information (command) of one Slave (slave axis) that is synchronized with Master (master axis)                                                                                                                              |
| Slave axis (output) absolute coordinate | Another term for the Slave axis absolute coordinate (SlaveAbsolute) for input variables of MC_CamTableSelect (Cam Table Selection)                                                                                                                           |
| SLMP                                    | A SeamLess Message Protocol.<br>This protocol is used to access an SLMP-compatible device or a programmable controller connected to an SLMP-compatible device from an external device.                                                                       |
| SW                                      | An abbreviation for a link special register. Word data that indicates the operating status and data link status of a module on CC-Link IE.                                                                                                                   |
| Switching speed                         | <ul style="list-style-type: none"> <li>• The set velocity of the on-going motion control FB when Aborting is specified</li> <li>• The command velocity when the on-going motion control FB reached the target position when Blending is specified</li> </ul> |
| System error                            | An error or a warning not related to an axis. When Axis information (Axis) and Axes Group Information (AxesGroup) of the motion control FBs are not correct, the system error will occur.                                                                    |
| Target position                         | A command position address that is specified in the motion FB                                                                                                                                                                                                |
| Transient transmission group number     | Number that is assigned for transient transmission to any given stations. By specifying a group of stations as transient transmission target, data can be sent to the stations of the same group No.                                                         |
| TSN hub                                 | A CC-Link IE TSN Class B switching hub authorized by CC-Link Partner Association                                                                                                                                                                             |
| Unicast mode                            | A communication mode used to send cyclic data to one station                                                                                                                                                                                                 |
| Virtual axis                            | An axis that is not linked with a device on network                                                                                                                                                                                                          |
| Virtual drive axis                      | A virtual axis that can generate a command virtually                                                                                                                                                                                                         |
| Virtual encoder axis                    | An axis that generates a commanded position from a variable. It is used as the master axis of the single axis synchronous control.                                                                                                                           |
| Virtual linked axis                     | An axis that connects FBs and transmits commands in the single axis synchronous control                                                                                                                                                                      |

# GENERIC TERMS AND ABBREVIATIONS

Unless otherwise specified, this manual uses the following generic terms and abbreviations.

| Generic term and abbreviation | Description                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CC-Link IE                    | A generic term for the following items: <ul style="list-style-type: none"> <li>• CC-Link IE TSN</li> <li>• CC-Link IE Controller Network</li> <li>• CC-Link IE Field Network</li> </ul>                                                                                                           |
| Controller                    | A generic term for the MXF100-8-N32, MXF100-8-P32, MXF100-16-N32, and MXF100-16-P32                                                                                                                                                                                                               |
| csp                           | An abbreviation for cyclic synchronous position mode (one of the control modes on the drive unit side)                                                                                                                                                                                            |
| cst                           | An abbreviation for cyclic synchronous torque mode (one of the control modes on the drive unit side)                                                                                                                                                                                              |
| csv                           | An abbreviation for cyclic synchronous velocity mode (one of the control modes on the drive unit side)                                                                                                                                                                                            |
| ct                            | An abbreviation for continuous operation to torque control mode (one of the control modes on the drive unit side)                                                                                                                                                                                 |
| Data link                     | A generic term for cyclic transmission and transient transmission                                                                                                                                                                                                                                 |
| Device supporting iQSS        | A device which supports iQ Sensor Solution.<br> iQ Sensor Solution Reference Manual                                                                                                                              |
| Drive unit                    | A generic term for motor drive devices such as a servo amplifier                                                                                                                                                                                                                                  |
| Engineering tool              | A tool used for setting up controllers or servo amplifiers, programming, debugging, and maintenance                                                                                                                                                                                               |
| Ethernet device               | A generic term for the devices supporting IP communication (such as a personal computer, a vision sensor, and a bar code reader)                                                                                                                                                                  |
| Ethernet-equipped module      | A generic term for the following modules: <ul style="list-style-type: none"> <li>• Controller (when the Ethernet function is used)</li> </ul>                                                                                                                                                     |
| GOT                           | A generic term for Mitsubishi Electric Graphic Operation Terminal GOT1000 and GOT2000 series                                                                                                                                                                                                      |
| hm                            | An abbreviation for homing mode (one of the control modes on the drive unit side)                                                                                                                                                                                                                 |
| I/O module                    | An input module, an output module, and an I/O module                                                                                                                                                                                                                                              |
| ICMP                          | An abbreviation for Internet Control Message Protocol. This protocol is used to exchange messages of errors in an IP network or other information related to an Ethernet network.                                                                                                                 |
| MCFB                          | An abbreviation for motion control FB                                                                                                                                                                                                                                                             |
| MR-J5(W)-G                    | A generic term for the MR-J5-_G/MR-J5-_G_-RJ/MR-J5-_G_-LL/MR-J5W-_G/MR-J5D-_G_ model servo amplifiers                                                                                                                                                                                             |
| Operation profile data        | A generic term for waveform data used for each control                                                                                                                                                                                                                                            |
| PDO                           | An abbreviation for Process Data Object. Aggregation of application objects transferred periodically between multiple CANopen nodes.                                                                                                                                                              |
| PTP                           | An abbreviation for Precision Time Protocol. A predefined protocol for time synchronization between devices on a network.                                                                                                                                                                         |
| SDO                           | An abbreviation for Service Data Object. A message to access an object entry in the object dictionary of a CANopen node. Data is sent/received between the stations aperiodically.                                                                                                                |
| SLMP                          | An abbreviation for Seamless Message Protocol. This protocol is used to access an SLMP-compatible device from an external device (such as a personal computer or HMI (Human Machine Interface)) or an SLMP-compatible module (such as the Ethernet-equipped module or modules on CC-Link IE TSN). |
| Station sub ID number         | An ID number of a sensor connected to a CC-Link-compatible communication module                                                                                                                                                                                                                   |

# 1 OVERVIEW

## 1.1 Instruction Configuration

Many instructions available for controllers are each divided into the instruction part and operand part.

The instruction part and operand part are used as follows.

- Instruction part: Indicates the function of the relevant instruction.
- Operand part: Indicates the data used for the instruction.

The operand part is further classified to source data, destination data, and numerical data.

### Source (s)

Source is the data used in the operation.

Depending on the label or device specified in each instruction, the source becomes as follows.

| Type            | Description                                                                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Constant        | The constant specifies a numerical value used in the operation.<br>It is set during program creation and cannot be changed during program execution.<br>When using constants in variable data, perform index modification.*1                                                                                                                           |
| Device<br>Label | The user specifies the device or label where the data to be used in the operation is stored.<br>Necessary data must be thus stored in the specified device or label before operation execution.<br>By changing the data to be stored in the specified device or label during program execution, the data to be used by the instruction can be changed. |

\*1 For the index modification, refer to the following.

 User's manual for the controller used

### Destination (d)

Data after operation is stored in the destination area.

However, some instructions require the data to be used in the operation to be stored before the operation.

**Ex.**

Binary 16-bit data addition instruction

(1) The data required for operation is stored before the operation.

(2) Only the operation result is stored.

A label or device to store data must be set for the destination.

## Numerical value (n)

For the numerical values of the numbers of devices, transfers, data, and character strings, specify those used by an instruction which uses multiple devices or an instruction which specifies the numbers of repetitions, data to be processed, and character strings.

**Ex.**

Block transfer instruction

(1) The number of transfers executed by the BMOV instruction is specified.

A numerical value from 0 to 65535 or 0 to 4294967295 can be set for the size such as the number of devices, transfers, or characters. <sup>\*1</sup>

Note, however, that when the size specification such as the number of devices, transfers, or characters is 0, the relevant instruction results in non-processing.

The upper limit of the numerical value may be less than the values mentioned above, depending on the capacity of the device memory or file storage area. <sup>\*2</sup>

<sup>\*1</sup> The setting range varies depending on the instruction. For details, refer to the description of each instruction.

<sup>\*2</sup> The capacities of the device memory and file storage area vary depending on models. For details, refer to the following.

User's manual for the controller used

### Point

Be careful when a large numerical value is used such as for the number of transfers. It delays the scan time.

# 1.2 Data Specification Method

The following table lists the types of data that can be used for instructions in controllers.

| Data                                   | Classification                    |
|----------------------------------------|-----------------------------------|
| Bit data                               | Bit data                          |
| 16-bit data (word data)                | 16-bit signed binary data         |
|                                        | 16-bit unsigned binary data       |
| 32-bit data (double word data)         | 32-bit signed binary data         |
|                                        | 32-bit unsigned binary data       |
| Real number data (floating-point data) | Single-precision real number data |
|                                        | Double-precision real number data |
| BCD data                               | BCD 4-digit data                  |
|                                        | BCD 8-digit data                  |
|                                        | BCD 16-digit data                 |
| String data                            | String                            |
|                                        | Unicode string                    |

## Device data

The following table lists devices and constants that can be used to specify the setting data of instructions.

| Data type                    | Description                                                                                                                                              | Specifiable device/constant <sup>*1</sup>                                                                                                                                                                               |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit                          | Bit data can be handled.<br>☞ Page 33 Bit data                                                                                                           | <ul style="list-style-type: none"> <li>• Bit device</li> <li>• Bit specification of word device</li> </ul>                                                                                                              |
| Word                         | Word data can be handled.<br>☞ Page 34 16-bit data (word data)                                                                                           | <ul style="list-style-type: none"> <li>• Word device</li> <li>• Digit-specified bit device (K1 to K4)<sup>*2</sup></li> </ul>                                                                                           |
| 16-bit signed binary         | 16-bit data can be handled.                                                                                                                              | <ul style="list-style-type: none"> <li>• Decimal constant</li> <li>• Hexadecimal constant</li> </ul>                                                                                                                    |
| 16-bit unsigned binary       | The value range varies depending on whether the value is signed or unsigned.<br>☞ Page 34 16-bit data (word data)                                        |                                                                                                                                                                                                                         |

| Unicode character string     | Unicode character string data can be handled.<br>☞ Page 42 String data                                                                                   | <ul style="list-style-type: none"> <li>• Word device</li> <li>• Character string constant</li> </ul>                                                                                                                    |
| Device name                  | A device can be specified directly.                                                                                                                      | <ul style="list-style-type: none"> <li>• Device name corresponding to applicable device</li> </ul>                                                                                                                      |

\*1 A constant can be used in the data specified for the source (s) or numerical data (n) by an instruction.

\*2 For the specification method, refer to the detail page of each data type.

## Label data

The following table lists labels that can be used to specify the setting data of instructions.

### ■ Primitive data type

| Data type (label)                                      | Specifiable label                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit<br>(BOOL)                                          | <ul style="list-style-type: none"> <li>• Bit type label</li> <li>• Bit-specified word [unsigned]/bit string [16 bits] type label</li> <li>• Bit-specified word [signed] type label</li> <li>• Timer/retentive timer/long timer/long retentive timer type label contact/coil</li> <li>• Counter/ long counter type label contact/coil</li> </ul> |
| Word [unsigned]/bit string [16 bits]<br>(WORD)         | <ul style="list-style-type: none"> <li>• Word [unsigned]/bit string [16 bits] type label</li> <li>• Digit-specified bit type label (K1 to K4)</li> <li>• Current value of timer/retentive timer type label</li> <li>• Current value of counter type label</li> </ul>                                                                            |

| Pointer<br>(POINTER)                                   | <ul style="list-style-type: none"> <li>• Pointer type label</li> </ul>                                                                                                                                                                                                                                                                          |

For details on individual labels, refer to the following.

User's manual for the controller used

## ■Generic data type

The generic data type is the data type of the labels which summarize several primitive data types.

Generic data types are used when multiple data types are allowed for arguments and return values of functions or function blocks.

Labels defined in generic data types can be used in any sub-level data type.

| Data type (label) |                |              |                          |            |            | Specifiable data type        |                                             |                                                     |            |
|-------------------|----------------|--------------|--------------------------|------------|------------|------------------------------|---------------------------------------------|-----------------------------------------------------|------------|
| ANY* <sup>1</sup> | ANY_ELEMENTARY | ANY_BIT      |                          |            |            | ANY_BOOL                     | Bit                                         |                                                     |            |
|                   |                |              |                          |            |            | ANY_BITADDR* <sup>1</sup>    | Bit                                         |                                                     |            |
|                   |                |              |                          |            |            | ANY16_U                      | Word [unsigned]/bit string [16 bits]        |                                                     |            |
|                   |                |              |                          |            |            | ANY32_U                      | Double word [unsigned]/bit string [32 bits] |                                                     |            |
|                   |                | ANY_WORDADDR | ANY_NUM                  | ANY_INT    | ANY16      | ANY16_S                      | Word [signed]                               |                                                     |            |
|                   |                |              |                          |            |            | ANY16_U                      | Word [unsigned]/bit string [16 bits]        |                                                     |            |

\*1 Can also be used as an array.

## ■Generic data type (array)

For the following generic data type, define the number of array elements.

| Data type (label) |                  |                         | Specifiable data type                             |
|-------------------|------------------|-------------------------|---------------------------------------------------|
| ANYBIT_ARRAY      |                  |                         | Bit array                                         |
| ANYWORD_ARRAY     | ANY16_ARRAY      | ANY16_S_ARRAY           | Word [signed] array                               |
|                   |                  | ANY16_U_ARRAY           | Word [unsigned]/bit string [16 bits] array        |
|                   | ANY32_ARRAY      | ANY32_S_ARRAY           | Double word [signed] array, time array            |
|                   |                  | ANY32_U_ARRAY           | Double word [unsigned]/bit string [32 bits] array |
|                   | ANY_REAL_ARRAY   | ANY_REAL_32_ARRAY       | Single-precision real number array                |
|                   |                  | ANY_REAL_64_ARRAY       | Double-precision real number array                |
|                   | ANY_STRING_ARRAY | ANY_STRING_SINGLE_ARRAY | Character string array                            |
|                   |                  | ANY_STRING_DOUBLE_ARRAY | Character string [Unicode] array                  |
| STRUCT_ARRAY      |                  |                         | Structure array                                   |

# Bit data

## Data size and data range

Bit data is handled in increments of bits such as contacts and coils.

| Data name | Data size | Value range |
|-----------|-----------|-------------|
| Bit data  | 1 bit     | 0, 1        |

## Handling bit data with bit devices and labels

One point of bit device/label can handle 1-bit data.

## Handling bit data with bit word devices

By specifying a bit number for a word device, bit data of the specified bit number can be handled.

A bit in a word device can be specified by "Word device number.Bit number".

A bit number can be specified in hexadecimal in the range from 0 to F.

For example, bit 5 (b5) of D0 is specified as D0.5, and bit 10 (b10) of D0 is specified as D0.A.

The following word devices support bit specification.

| Item                                         | Device                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Word devices which support bit specification | <ul style="list-style-type: none"> <li>• Data register (D)</li> <li>• Link register (W, J□\W)</li> <li>• Link special register (SW, J□\SW)</li> <li>• Function register (FD)</li> <li>• Special register (SD)</li> <li>• Module access device (U□\G)</li> <li>• CPU Buffer memory access device (U3E□\G)</li> <li>• File register (R, ZR)</li> <li>• Module refresh register (RD)</li> </ul> |

## Handling bit data with word type labels

By specifying a bit number for a word type label, bit data of the specified bit number can be handled.

A bit in a word type label can be specified by "Label name.Bit number".

**Ex.**

The following data types of labels support bit specification.

| Item                                                  | Data type                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data types of labels which support bit specification. | <ul style="list-style-type: none"> <li>• Word [signed] (INT type)</li> <li>• Word [unsigned]/bit string [16 bits] (WORD type)</li> <li>• Current value (N) of timer (TIMER type)*1</li> <li>• Current value (N) of retentive timer (RETENTIVETIMER type)*1</li> <li>• Current value (N) of counter (COUNTER type)*1</li> </ul> |

\*1 Cannot be specified in ladder programs.

## 16-bit data (word data)

### Data size and data range

16-bit data includes signed and unsigned 16-bit data.

In signed 16-bit data, a negative number is represented in two's complement.

| Data name            | Data size        | Value range      |                      |
|----------------------|------------------|------------------|----------------------|
|                      |                  | Decimal notation | Hexadecimal notation |
| Signed 16-bit data   | 16 bits (1 word) | -32768 to 32767  | 0000H to FFFFH       |
| Unsigned 16-bit data |                  | 0 to 65535       |                      |

### Handling 16-bit data with bit devices

A bit device can be handled as 16-bit data by performing digit specification.

| Item       |                               | Notation                                                                                                                                              | Example             |
|------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| Bit device | Other than link direct device | K□Bit device start number<br>□: Number of digits (Specify the number within the range of 1 to 4.)                                                     | K4X40<br>K2M113     |
|            | Link direct device            | J□K□Bit device start number<br>□ (on the left): Network number<br>□ (on the right): Number of digits (Specify the number within the range of 1 to 4.) | J1K3B10<br>J10K2Y40 |

### Handling 16-bit data with bit type array labels

A bit type array label can be handled as 16-bit data by performing digit specification.

The following table shows the notation for handling a bit type array label as 16-bit data by digit specification.

| Item                 | Notation                                                                                                                               | Example  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|----------|
| Bit type array label | K□Label name<br>□: Number of digits (Specify the number within the range of 1 to 4.)<br>Specify a label name without an array element. | K1L_BOOL |

## Digit specification range

The following table lists the range of 16-bit data for each digit specification.

| Digit specification | Decimal notation                                                        | Hexadecimal notation |
|---------------------|-------------------------------------------------------------------------|----------------------|
| K1                  | 0 to 15                                                                 | 0H to FH             |
| K2                  | 0 to 255                                                                | 00H to FFH           |
| K3                  | 0 to 4095                                                               | 000H to FFFH         |
| K4                  | Signed 16-bit data: -32768 to 32767<br>Unsigned 16-bit data: 0 to 65535 | 0000H to FFFFH       |

### Ex.

When digit specification is made for X40, the applicable number of points is as follows.

- K1X40→4 points from X40 to X43
- K2X40→8 points from X40 to X47
- K3X40→12 points from X40 to X4B
- K4X40→16 points from X40 to X4F

## Specifying a bit device with digit specification in the source (s)

When a bit device is specified with digit specification in the source of an instruction, 0 is stored in the word device of the destination, in the upper bits than those specified in the source of the instruction.

| Ladder example                   | Processing |
|----------------------------------|------------|
| <p>• 16-bit data instruction</p> |            |

## Specifying a bit device with digit specification in the destination (d)

When a digit specification is made in the destination of an instruction, the number of points by the digit specification is applicable in the destination.

The upper bit devices than the number of points specified by digits remain unchanged.

| Ladder example                                 | Processing                           |
|------------------------------------------------|--------------------------------------|
| <p>• When the source data is a word device</p> | <p>(1) The data remain the same.</p> |

## Handling 16-bit data with word devices/labels

### ■Word device

One point of word device can handle 16-bit data.

### ■Word type label

One point of word type label can handle 16-bit data.

## 32-bit data (double word data)

### Data size and data range

32-bit data includes signed and unsigned 32-bit data.

In signed 32-bit data, a negative number is represented in two's complement.

| Data name            | Data size        | Value range               |                        |
|----------------------|------------------|---------------------------|------------------------|
|                      |                  | Decimal notation          | Hexadecimal notation   |
| Signed 32-bit data   | 32 bits (2 word) | -2147483648 to 2147483647 | 00000000H to FFFFFFFFH |
| Unsigned 32-bit data |                  | 0 to 4294967295           |                        |

### Handling 32-bit data with bit devices

A bit device can be handled as 32-bit data by performing digit specification.

| Item       |                               | Notation                                                                            | Example              |
|------------|-------------------------------|-------------------------------------------------------------------------------------|----------------------|
| Bit device | Other than link direct device |   | K8X80<br>K6B018      |
|            | Link direct device            |  | J1K7B30<br>J10K5X128 |

### Handling 32-bit data with bit type array labels

A bit type array label can be handled as 32-bit data by performing digit specification.

The following table shows the notation for handling a bit type array label as 32-bit data by digit specification.

| Item                 | Notation                                                                                                                                                                                                                                                                                                                                                  | Example  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| Bit type array label | <br><br>Specify a label name without an array element.<br>For languages other than ladder, specify the number within the range of K5 to K8.<br>(For languages other than ladder, the label with digit specification within the range of K1 to K4 is handled as ANY16.) | K8L_BOOL |

## Digit specification range

The following table lists the range of 32-bit data for each digit specification.

| Digit specification | Decimal notation                                                                       | Hexadecimal notation   |
|---------------------|----------------------------------------------------------------------------------------|------------------------|
| K1                  | 0 to 15                                                                                | 0H to FH               |
| K2                  | 0 to 255                                                                               | 00H to FFH             |
| K3                  | 0 to 4095                                                                              | 000H to FFFH           |
| K4                  | 0 to 65535                                                                             | 0000H to FFFFH         |
| K5                  | 0 to 1048575                                                                           | 00000H to FFFFFH       |
| K6                  | 0 to 16777215                                                                          | 000000H to FFFFFFFH    |
| K7                  | 0 to 268435455                                                                         | 0000000H to FFFFFFFFH  |
| K8                  | Signed 32-bit data: -2147483648 to 2147483647<br>Unsigned 32-bit data: 0 to 4294967295 | 00000000H to FFFFFFFFH |

### Ex.

When digit specification is made for X40, the applicable number of points is as follows.

- K1X40→4 points from X40 to X43
- K2X40→8 points from X40 to X47
- K3X40→12 points from X40 to X4B
- K4X40→16 points from X40 to X4F
- K5X40→20 points from X40 to X53
- K6X40→24 points from X40 to X57
- K7X40→28 points from X40 to X5B
- K8X40→32 points from X40 to X5F

## ■Specifying a bit device with digit specification in the source (s)

When a bit device is specified with digit specification in the source of an instruction, 0 is stored in the word device of the destination, in the upper bits than those specified in the source of the instruction.

| Ladder example                                                                                                                                              | Processing                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>32-bit data instruction</li> </ul>  |  |

## ■Specifying a bit device with digit specification in the destination (d)

When a digit specification is made in the destination of an instruction, the number of points by the digit specification is applicable in the destination.

The upper bit devices than the number of points specified by digits remain unchanged.

| Ladder example                                                                                                                                                             | Processing                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>When the source data is a word device</li> </ul>  |  <p>(1) The data remain the same.</p> |

## Handling 32-bit data with word devices/labels

### ■Word device

Two points of word device can handle 32-bit data.

Note, however, that one point of the following devices can handle 32-bit data.

- Long timer (LT)
- Long retentive timer (LST)
- Long counter (LC)
- Long index register (LZ)

### ■Double word type label

One point of double word device can handle 32-bit data.

# Real number data (floating-point data)

## Data size and data range

Real number data includes single-precision 32-bit real number data and double-precision 64-bit real number data.

Real number data can be stored only in devices other than bit devices or in single-precision or double-precision real data type labels.

| Data name                                                                |                 | Data size        | Value range                                      |
|--------------------------------------------------------------------------|-----------------|------------------|--------------------------------------------------|
| Single-precision real number data (single-precision floating-point data) | Positive number | 32 bits (2 word) | $2^{-126} \leq \text{real number} < 2^{126}$     |
|                                                                          | Zero            |                  | 0                                                |
|                                                                          | Negative number |                  | $-2^{126} < \text{real number} \leq -2^{-126}$   |
| Double-precision real number data (double-precision floating-point data) | Positive number | 64 bits (4 word) | $2^{-1022} \leq \text{real number} < 2^{1024}$   |
|                                                                          | Zero            |                  | 0                                                |
|                                                                          | Negative number |                  | $-2^{1024} < \text{real number} \leq -2^{-1022}$ |

## Configuration of single-precision real number data

Single-precision real number data consists of a sign, mantissa, and exponent, and is expressed as shown below.

The following figure shows the bit configuration of the internal expression of single-precision real number data and the meaning of each part.

### ■Sign (1 bit)

This bit represents the positive or negative sign of a numerical value. "0" indicates a positive number or 0. "1" Indicates a negative number.

### ■Mantissa (23 bits)

A mantissa means XXXXX... of  $1.XXXXX \times 2^N$  representing a single-precision real number in binary.

### ■Exponent (8 bits)

An exponent means N of  $1.XXXXX \times 2^N$  representing a single-precision real number in binary. The following table shows the relationships between the exponent value and N of a single-precision real number.

| Exponent (b24 to b30) | FFH      | FEH | FDH | ... | 81H | 80H | 7FH | 7EH | ... | 02H  | 01H  | 00H      |
|-----------------------|----------|-----|-----|-----|-----|-----|-----|-----|-----|------|------|----------|
| N                     | Not used | 127 | 126 | ... | 2   | 1   | 0   | -1  | ... | -125 | -126 | Not used |

## Configuration of double-precision real number data

Double-precision real number data consists of a sign, mantissa, and exponent, and is expressed as shown below.

The following figure shows the bit configuration of the internal expression of double-precision real number data and the meaning of each part.

### ■Sign (1 bit)

This bit represents the positive or negative sign of a numerical value. "0" indicates a positive number or 0. "1" Indicates a negative number.

### ■Mantissa (52 bits)

A mantissa means XXXXX... of  $1.XXXXX... \times 2^N$  representing a single-precision real number in binary.

### ■Exponent (11 bits)

An exponent means N of  $1.XXXXX... \times 2^N$  representing a single-precision real number in binary. The following table shows the relationships between the exponent value and N of a single-precision real number.

| Exponent (b52 to b62) | 7FFH     | 7FEH | 7FDH | ... | 401H | 400H | 3FFH | 3FEH | ... | 02H   | 01H   | 00H      |
|-----------------------|----------|------|------|-----|------|------|------|------|-----|-------|-------|----------|
| N                     | Not used | 1023 | 1022 | ... | 2    | 1    | 0    | -1   | ... | -1021 | -1022 | Not used |

## Precautions

### ■When setting an input value of single-precision real number from the engineering tool

The number of significant digits is about 7 because the engineering tool processes single precision real number data in 32-bit single precision.

When the input value of single-precision real number data exceeds 7 digits, the 8th digit is rounded off.

Therefore, if the rounded-off value goes out of the range from -2147483648 to 2147483647, it will not be an intended value.

**Ex.**

When "2147483647" is set as an input value, it is handled as "2147484000" because 8th digit "6" is rounded off.

**Ex.**

When "E1.1754943562" is set as an input value, it is handled as "E1.175494" because 8th digit "3" is rounded off.

Set an input value within the following range. If the set value is out of the following range, a conversion error occurs.

Decimal point expression:  $0.0000000001 \leq \text{Absolute value of real number data} \leq 999999900000.0$

Exponential notation:  $1.175494351\text{E}-38 \leq \text{Absolute value of real number data} \leq 3.402823466\text{E}+38$

# String data

## Format of character string data

The following table lists the types of character string data, each of which ends with a NULL code to be handled as a character string.

| Type                     | Character code                   | Last character |
|--------------------------|----------------------------------|----------------|
| Character string         | ASCII code, Shift JIS code       | NULL(00H)      |
| Unicode character string | Unicode (UTF-16 (little endian)) | NULL(0000H)    |

Character string data is stored in devices or an array in ascending order of device numbers or array element numbers.

(1) Character code string

## Notation of character string

The following shows the notation of character strings in ladder programs.

| Data type                  | Notation | Example                                                                                         |
|----------------------------|----------|-------------------------------------------------------------------------------------------------|
| String                     | STRING   | Enclose a string (ASCII code, Shift JIS code) and Unicode string in double quotation marks ("). |
| Character string [Unicode] | WSTRING  | "ABC"                                                                                           |

The following shows the notation of character strings in ST programs.

| Data type                  | Notation | Example                                                                      |
|----------------------------|----------|------------------------------------------------------------------------------|
| String                     | STRING   | Enclose a string (ASCII code, Shift JIS code) in single quotation marks ('). |
| Character string [Unicode] | WSTRING  | Enclose a Unicode string in double quotation marks (").                      |

The following shows the notation of character strings in FBD/LD programs.

| Data type                  | Notation | Example                                                                      |
|----------------------------|----------|------------------------------------------------------------------------------|
| String                     | STRING   | Enclose a string (ASCII code, Shift JIS code) in single quotation marks ('). |
| Character string [Unicode] | WSTRING  | Enclose a Unicode string in double quotation marks (").                      |

## Data range

The following table summarizes the ranges of character string data.

| Type                                   | Maximum number of characters that can be set in a label        | Maximum number of characters that can be used for character string constant |
|----------------------------------------|----------------------------------------------------------------|-----------------------------------------------------------------------------|
| Character string                       | 255 single-byte characters (excluding the last NULL character) | 255 single-byte characters (excluding the last NULL character)              |
| Unicode character string <sup>*1</sup> | 255 characters (excluding the last NULL character)             | 255 characters (excluding the last NULL character)                          |

<sup>\*1</sup> For the Unicode character string, characters up to the basic multilingual plane can be used.

## Number of words required for storing data

Character string data can be stored in word devices.

The following table lists the numbers of words required for storing character string data.

| Number of character string bytes | Number of words required for storing character strings         | Number of words required for storing Unicode character strings |
|----------------------------------|----------------------------------------------------------------|----------------------------------------------------------------|
| 0 byte                           | 1 [word]                                                       | 1 [word]                                                       |
| Odd number of bytes              | $(\text{Number of character string bytes} + 1) \div 2$ [words] | — (because one character is an even number of bytes)           |
| Even number of bytes             | $(\text{Number of character string bytes} \div 2) + 1$ [words] | Number of characters + 1 [words]                               |

## Character string data storage location

An image of the character string data storage location is shown below.

### ■Character strings

In each character string storage image, "NULL" indicates a NULL code (00H).

| Character string to be stored      | Image of storing character string data from D0                                                                                                                                            | Image of storing character string data from word type label array arrayA[0] |   |      |                                                                        |      |   |                                                                                                                                         |   |      |                                                                                                                                                                                                                |      |   |   |   |   |   |      |   |      |

### ■Unicode character strings

In each Unicode character string storage image, "NULL" indicates a NULL code (0000H).

| Character string to be stored | Image of storing character string data from D0 | Image of storing character string data from word type label array arrayA[0] |
|-------------------------------|------------------------------------------------|-----------------------------------------------------------------------------|
| Null character string ("")    | D0 <div><div>NULL</div></div>                  | arrayA[0] <div><div>NULL</div></div>                                        |
| ABCD                          | D0 <div><div>A</div></div>                     | arrayA[0] <div><div>A</div></div>                                           |
|                               | D1 <div><div>B</div></div>                     | arrayA[1] <div><div>B</div></div>                                           |
|                               | D2 <div><div>C</div></div>                     | arrayA[2] <div><div>C</div></div>                                           |

|                               | D4 <div><div>NULL</div></div>                  | arrayA[4] <div><div>NULL</div></div>                                        |

# 1.3 Execution Condition

## Types of execution conditions

The following table lists the execution conditions of instructions.

| Execution condition |                                                                                   | Description <sup>*1</sup>                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| On                  |  | An instruction is executed during on. It is executed only while the precondition of the instruction is on. When the precondition is off, the instruction is not executed.                                               |
| Rising edge         |  | An instruction is executed one time when turned on. It is executed only once on the rising edge (off to on) of the precondition of the instruction and is no longer executed later even when the condition turns on.    |
| Off                 |  | An instruction is executed during off. It is executed only while the precondition of the instruction is off. When the precondition is on, the instruction is not executed.                                              |
| Falling edge        |  | An instruction is executed one time when turned off. It is executed only once on the falling edge (on to off) of the precondition of the instruction and is no longer executed later even when the condition turns off. |
| Every scan          | —                                                                                 | An instruction is always executed regardless of whether the precondition of the instruction is on or off. When the precondition is off, the instruction performs off processing.                                        |

<sup>\*1</sup> When the program is described in structured text language (ST) or function block diagram/ladder diagram (FBD/LD), EN will be the precondition of the instruction.

## Execution condition of each instruction

The execution condition varies depending on the instruction. For execution condition, refer to the details of each instruction in this manual.

When the program is described in structured text language (ST) or function block diagram/ladder diagram (FBD/LD), EN will be the execution condition. The instruction is executed only when EN is TRUE. The status of ENO will be the same as that of EN.

Note that the execution condition of standard functions and function blocks differs depending on the existence of EN. If there is no EN, the standard function or function block is executed at every scan. For the execution condition of the standard function or function block with EN, refer to the details of each standard function or function block in this manual.

For the execution conditions on the motion control function blocks, refer to the following.

 Page 1431 Execution command (Execute) type/Enable (Enable) type

# 1.4 Precautions on Programming

## Errors common to instructions

The following table lists the conditions under which an error occurs when the instruction is executed.

| Error description <sup>*1</sup>                                                                                                                                                                                                                                                                             | Error code |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| An I/O number which is out of range (other than 000H to FFFH and 3E0H to 3E3H) is specified.                                                                                                                                                                                                                | 2800H      |
| An I/O number which corresponds to no module is specified.                                                                                                                                                                                                                                                  | 2801H      |
| An I/O number of the module that cannot be specified by using the instruction is specified.                                                                                                                                                                                                                 | 2803H      |
| A network number which is out of range (1 to 239) is specified.                                                                                                                                                                                                                                             | 2804H      |
| A network number which does not exist is specified.                                                                                                                                                                                                                                                         | 2805H      |
| <ul style="list-style-type: none"> <li>The device or label specified by the instruction exceeds the available range.</li> <li>The file register is accessed while the file register is not set in the file setting of a CPU parameter or the file register to be used in the program is not set.</li> </ul> | 2820H      |
| <ul style="list-style-type: none"> <li>The range of the buffer memory of the module specified by the instruction is exceeded.</li> <li>The module specified by the instruction does not have buffer memory.</li> </ul>                                                                                      | 2823H      |

\*1 For a contact instruction, an error is not detected but the operation result becomes no continuity.

## Checking the ranges of instruction runtime devices and labels

### Device range check

When a device is specified in an instruction, range check is performed, so a program needs to be created so that the operation result falls within the range of the relevant device.

If a range exceeding that of the relevant device is specified, an error (error code: 2820H) occurs.

The same applies if the label assigned to a device is specified in an instruction in the program.

**Ex.**

When W0 is assigned after global device D1023 in the device memory

(1) The transfer destination is in the range corresponding to D1023 to D1032. An error occurs because the range from D1024 to D1032 does not exist.

**Ex.**

When local devices are set in the range from M0 to M63 or D0 to D11

- (2) The transfer destination is in the range corresponding to local devices #M48 to #M239 of program A. An error occurs because the range from M64 to #M239 does not exist.

## Checking the range of file register

When a file register is specified in an instruction, a range check is performed, so a program needs to be created so that the operation result falls within the range of the relevant file register.

If a range exceeding that of the file register (ZR) is specified, an error (error code: 2820H) occurs.

If a range exceeding that of the file register of the block number used by the file register (R) is specified, an error (error code: 2820H) occurs.

### Ex.

When a file register (ZR) is specified

(1) The transfer destination is in the range of file register MAIN1. Data is written to ZR0 and ZR1.

(2) The transfer destination is out of the range of file register MAIN1. An error occurs because the area range of file register MAIN1 is exceeded.

### Ex.

When a file register (R) is specified

(1) The transfer destination is in the range of the R device of block number 0. Data is written to R0 and R1.

(2) The transfer destination is out of the range of the R device of block number 0. An error occurs because the area range of the R device of block number 0.

Global (latch) label and local (latch) label range check

When a global (latch) label or local (latch) label is specified in an instruction, range check is performed, so a program needs to be created so that the operation result falls within the range of the relevant label. For digit specification or bit specification as well, specify a value within the range of the relevant label.

If a range exceeding that of the relevant device is specified, an error (error code: 2820H) occurs.

■Array label

When an array label is specified for an argument, the entire array label is checked. When elements of an array label are specified as well, values within the range of the array label are checked.

Ex.

When labels are arrayed as follows

| Label name | Data type            | Number of array elements |
|------------|----------------------|--------------------------|
| labelA     | Bit string [16 bits] | 2                        |
| abc        | Bit string [16 bits] | 10                       |

(1) The transfer destination is in the range corresponding to 10 points from labelA[1]. An error occurs because the range from labelA[2] to labelA[9] does not exist.

## ■ Structure type label

When a structure type label is specified for an argument, the entire structure type label is checked. When a structure member is specified, values within the range that corresponds to the data type of the relevant member are checked.

**Ex.**

When labels are arrayed as follows

| Label name | Data type                 |                           | Member   |
|------------|---------------------------|---------------------------|----------|
| stLabelA   | Structure A               | Word/bit string [16 bits] | memberA1 |
|            |                           | Word/bit string [16 bits] | memberA2 |
| abc        | Word/bit string [16 bits] |                           | —        |

- When a structure type label is specified

(1) The transfer destination is in the range corresponding to 4 points from the start of the structure type label "stLabelA". Because access is in the range that includes two points for padding in the structure, data is written.

- When the member "memberA1" is specified

(1) The transfer destination is in the range corresponding to 2 points from the start of memberA1. Because the range of memberA1 corresponds to one point, an error occurs.

Module label and network label range check

When a module label or network label is specified in an instruction, range check is performed in the network label/module label assignment area. Therefore, create a program so that the operation result falls within the range of the network label/module label assignment area.

If a range exceeding that of the relevant network label/module label assignment area is specified, an error (error code: 2820H) occurs.

For details on the setting method of the network label/module label assignment area, check the user's manual for the controller used.

Ex.

When module labels are set as follows

| Instance name | Label name | Data type       | Assignment device |
|---------------|------------|-----------------|-------------------|
| Module        | label0     | Word [unsigned] | UV: 0             |
|               | label1     | Word [unsigned] | UV: 1             |
|               | label2     | Word [unsigned] | UV: 2             |
|               | label3     | Word [unsigned] | UV: 3             |
|               | label4     | Word [unsigned] | UV: 4             |

- (1) The transfer destination is within the range of the network label/module label assignment area. It is written to Module.label0 to Module.label4. Data is written even if the data type is crossed.
- (2) Although the area is outside the transfer destination range, it is within the network label/module label assignment area, so this area can be accessed.

# Operation when a long timer or long retentive timer device is used

When the data to be handled exceeds the width (32 bits) of the current value, the long timer or long retentive timer operates by using not only the area of the current value but also the areas of the previous value, contact, and coil.

| Device                     | Configuration                                                                                                                                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timer (T)                  | <div> <div>T0</div> <div>T0</div> </div>                                                                                                                                                                                       |
| Retentive timer (ST)       | <div> <div>.....</div> <div>Contact</div> <div>Coil</div> </div>                                                                                                                                                               |
| Counter (C)                | <div> <div>Current value</div> <div>T0</div> <div>.....</div> <div>T1</div> <div>Current value</div> <div>T2</div> </div>                                                                                                      |
| Long timer (LT)            | <div> <div>Current value</div> <div>LT0</div> <div>FRT previous value</div> <div>Contact</div> <div>Coil</div> <div>Current value</div> <div>LT1</div> <div>FRT previous value</div> <div>Contact</div> <div>Coil</div> </div> |
| Long retentive timer (LST) |                                                                                                                                                                                                                                |
| Long counter (LC)          | <div> <div>LC0</div> <div>LC0</div> <div>.....</div> <div>Contact</div> <div>Coil</div> <div>Current value</div> <div>LC0</div> <div>Current value</div> <div>LC1</div> </div>                                                 |

When the BMOV instruction is used to batch-transfer current values, current values alone cannot be batch-transferred. Batch-transfer the current values, contacts, and coils altogether and, after the batch transfer is finished, use only the current values. When the DMOV instruction is used to batch-transfer current values, repeat the transfer of the current values alone using the FOR to NEXT instruction.

## Ex.

To batch-transfer the current values of the timer device

When the BMOV instruction is used, only current values are batch-transferred.

**Ex.**

To batch-transfer the current values of the long timer device

When the BMOV instruction is used, all current values, contacts, and coils are batch-transferred.

When the DMOV instruction is used, only current values are batch-transferred.

## Precautions for using a link device assigned to a synchronized station as an instruction argument

When using a link device assigned to a synchronized station in CC-Link IE TSN as an instruction argument, set link refresh and then specify the refresh target device or label. If direct access device (U□\G□, J□\□) is specified to an instruction argument, the link device does not operate correctly.

For details on CC-Link IE TSN, check the user's manual for the controller used.

## Operations arising when the OUT, SET/RST, and PLS/PLF instructions of the same device are used

This section describes the operation when two or more OUT, SET/RST, and PLS/PLF instructions that use the same device are executed within one scan.

### For OUT instructions of the same device

More than one OUT instruction of the same device must not be issued during one scan.

Otherwise, the specified device turns on or off, depending on the operation result up to each OUT instruction while it is in execution.

In this case, the device may turn on/off during one scan because the on/off state of the specified device is determined during execution of each OUT instruction.

The following figure shows the behavior arising when a circuit turning on/off the same internal relay (M0) is created with input X40 and X41.

- (1) Since X40 is on, M0 turns on.
- (2) Since X41 is off, M0 turns off.
- (3) Since X40 is off, M0 remains off.
- (4) Since X41 is on, M0 turns on.

If output (Y) is specified using an OUT instruction, the on/off state of the last OUT instruction executed during the one scan will be output.

## If SET/RST instructions of the same device are used

### ■For SET instructions

The SET instruction turns on the specified device if the execution command is on, and causes no operation if it is off.

Thus, if two or more SET instructions of the same device are executed during one scan, the specified device turns on even if one execution command is on.

### ■For RST instructions

The RST instruction turns on the specified device if the execution command is off, and causes no operation if it is off.

Thus, if two or more RST instructions of the same device are executed during one scan, the specified device turns on even if one execution command is off.

### ■If the SET and RST instructions of the same device exist in one scan

If the SET and RST instructions of the same device exist in one scan, the SET instruction turns on the specified device if the execution command is on, and turns off the specified device if it is on.

If both the SET and RST instructions are off, the on/off state of the specified device will be unchanged.

(1) Since X40 is on, M0 turns on.

(2) Since X41 is off, M0 remains on. (The RST instruction results in non-processing.)

(3) Since X40 is off, M0 remains on. (The SET instruction results in non-processing.)

(4) Since X41 is on, M0 turns off.

If output (Y) is specified using a SET/RST instruction, the on/off state of the last SET/RST instruction executed during the one scan will be output.

## If PLS instructions of the same device are used

The PLS instruction turns on the specified device when the execution command specifies an off-to-on change. The specified device is turned off unless the execution command specifies an off-to-on change (i.e. off to off, on to on, on to off).

Thus, if two or more PLS instructions of the same device are issued during one scan, the specified device is turned on when the execution command of each PLS instruction specifies an off-to-on change. The specified device is turned off unless the execution command specifies an off-to-on change.

Thus, if two or more PLS instructions are issued during one scan, the device turned on by a PLS instruction may not turn on for one scan.

- If X40 and X41 differ in the on/off timing (i.e. the specified device does not turn on for one scan)

- (1) Since X40 turns on, M0 turns on.
- (2) Since X41 is other than turning on, M0 turns off.
- (3) Since X40 is other than turning on, M0 remains off.
- (4) Since X41 turns on, M0 turns on.

- If the off-to-on changes of X40 and X41 are at the same timing

- (1) Since X40 turns on, M0 turns on.
- (2) Since X41 turns on, M0 remains off.
- (3) Since X40 is other than turning on, M0 turns off.
- (4) Since X41 is other than turning on, M0 remains off.

If output (Y) is specified using a PLS instruction, the on/off state of the last PLS instruction executed during the one scan will be output.

## If PLF instructions of the same device are used

The PLF instruction turns on the specified device when the execution command specifies an off-to-on change. The specified device is turned off unless the execution command specifies an on-to-off change (i.e. off to off, off to on, on to on).

Thus, if two or more PLF instructions of the same device are issued during one scan, the specified device is turned on when the execution command of each PLF instruction specifies an on-to-off change. The specified device is turned off unless the execution command specifies an on-to-off change.

Thus, if two or more PLF instructions are issued during one scan, the device turned on by a PLF instruction may not turn on for one scan.

- If X40 and X41 differ in the on/off timing (i.e. the specified device does not turn on for one scan)

- (1) Since X40 turns off, M0 turns on.
- (2) Since X41 is other than turning off, M0 turns off.
- (3) Since X40 is other than turning off, M0 remains off.
- (4) Since X41 is other than turning off, M0 remains off.

- If the on-to-off changes of X40 and X41 are at the same timing

- (1) Since X40 turns off, M0 turns on.
- (2) Since X41 turns off, M0 remains on.
- (3) Since X40 is other than turning off, M0 turns off.
- (4) Since X41 is other than turning off, M0 remains off.

If output (Y) is specified using a PLF instruction, the on/off state of the last PLF instruction executed during the one scan will be output.

# Restrictions on using file registers

When a file register is specified for the refresh device, note the following restrictions.

1

## When the block number is changed by the RSET instruction

When the block number is changed by the RSET instruction, note the following.

- Data is refreshed by the file register (R) of the new block number.
- Data is refreshed by the file register (R) of the block number immediately before refresh.

To read or write refresh data, specify the block number immediately before refresh.

# 2

## PROGRAM ORGANIZATION UNITS

There are three types of program organization units (POUs).

- Program block
- Function
- Function block

Processing can be described in the programming language that suits the control performed in each POU. Processing can be described in the ladder diagram, structured text language, or FBD/LD in a function or a function block.

Functions and function blocks are called and executed by program blocks.

### Point

A structured program is a program created by components. Processes in lower levels of hierarchical sequence program are divided into several components according to their processing information and functions.

Each component of a program is specified to have a high degree of independence for easy addition and replacement.

The following are the examples of processing that would be ideal to be structured.

- Processing which is used repeatedly in a program
- Processing which can be separated as one function

This chapter describes two types of POUs using labels.

Devices can also be used in the program (worksheet) of each POU. For details on devices, refer to the following.

User's manual for the controller used

### Point

Up to 32 worksheets can be created in one POU in the structured text language and FBD/LD.

Set the execution order of multiple worksheets on the "Worksheet Execution Order Setting" window of the engineering tool. ( GX Works3 Operating Manual)

## 2.1 Program Blocks

A program block is a unit for making up a program.

Multiple program blocks can be created in a program file and executed in the order specified in the program file setting. If the order is not specified in the program file setting, the program blocks are executed in ascending order of their names.

By separating program blocks for individual functions and processing, the order of programs can be changed easily and programs can be exchanged easily.

The program of a program block is stored by each registration destination program in a program file.

### Dividing into program blocks

A main routine program, subroutine program, and interrupt program can be created separately in individual program blocks.

| Program type         | Description                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Main routine program | A program beginning with step 0 and ending with the FEND instruction                                                                                                                                         |
| Subroutine program   | A program beginning with a pointer (P) and ending with the RET instruction.<br>This program is executed only when it is called by a subroutine call instruction (such as the CALL and ECALL instructions).   |
| Interrupt program    | A program beginning with an interrupt pointer (I) and ending with the IRET instruction.<br>When an interrupt factor occurs, the interrupt program corresponding to the interrupt pointer number is executed. |

#### Point

- Create a subroutine program and interrupt program after the FEND instruction of the main routine program. Any program after the FEND instruction is not executed as a main routine program. For example, when the FEND instruction is used at the end of the second program block, the third program block or later runs as a subroutine program or interrupt program.
- To create an easy-to-understand program, use a pair of instructions, such as the FOR and NEXT instructions or the MC and MCR instructions, within a single program block.
- A simple program can be executed in the controller simply by writing the main routine in one program block.

For details on the subroutine program and interrupt program, refer to the following.

User's manual for the controller used

## 2.2 Functions (FUN)

A function is a POU called and executed by program blocks, function blocks, and other functions.

After the processing completes, a function passes a value to the calling source. This value is called a return value.

A function always outputs the same return value, as the processing result, for the same input.

By defining simple, independent algorithms that are frequently used, functions can be reused efficiently.

### Operation overview

The program of a function is stored in the FUN file and called by the calling source program when executed.

**Ex.**

When calling FUN1 and FUN2 from the main program, and calling FUN3 by FUN1 (Nested three times)

➊ to ➋ indicate the execution flow (order).

Up to 32 subroutine type function blocks and functions in total can be nested.

## Input variables and output variables

Input and output variables can be defined in functions. Output data which is different from the return value can be assigned to the output variable.

Ladder program

FBD/LD program

- (1) Function name
- (2) Input variable
- (3) Output variable

The return value of the function is not displayed.

Input variables are set in the VAR\_INPUT class and output variables are set in the VAR\_OUTPUT class.

### Point

Variables defined in the function are overwritten every time the function is called.

To hold the data in the variables, create a program by using function blocks or so that the data in the output variable is saved in another variable.

## EN and ENO

EN (enable input) and ENO (enable output) can be appended to a function to control execution processing.

- Set a boolean variable used as an execution condition of a function to EN.
- A function with EN is executed only when the execution condition of EN is TRUE.
- Set a boolean variable used to output a function execution result to ENO.

The following table lists the ENO states and operation results according to the EN states.

| EN                   | ENO   | Operation result              |
|----------------------|-------|-------------------------------|
| TRUE (executed)      | TRUE  | Operation result output value |
| FALSE (not executed) | FALSE | Undefined value               |

### Point

- Setting an output label to ENO is not always required for the program written in ladder or FBD/LD.
- When EN/ENO is used in a standard function, the function with EN is represented by "function-name\_E".

## Creating programs

The program of a function can be created by using the engineering tool.

 [Navigation window] ⇒ [FB/FUN] ⇒ Right-click ⇒ [Add New Data]  
Select "Function" for "Data Type" in "Basic Setting".

The created program is stored in the FUN file.

 [CPU Parameter] ⇒ [Program Setting] ⇒ [FB/FUN File Setting]

Up to 64 created programs can be stored in one FUN file.

The rising edge execution instruction or falling edge execution instruction cannot be used in the function.

For details on program creation, refer to the following.

| Item                                                       | Reference                                                                                                               |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| How to create function programs                            |  GX Works3 Operating Manual            |
| Number of FB/FUN files that can be written to a controller |  User's manual for the controller used |

### ■Applicable devices and labels

The following table lists the devices and labels that can be used in function programs.

○: Applicable, △: Applicable only in instructions (Cannot be used to indicate the program step.), ×: Not applicable

| Type of device/label                |                           | Availability |
|-------------------------------------|---------------------------|--------------|
| Label (other than the pointer type) | Global label              | ×            |
|                                     | Local label               | ○*1          |
| Label (pointer type)                | Pointer type global label | ×            |
|                                     | Pointer type local label  | ○            |
| Device                              | Global device             | ○            |
|                                     | Local device              | ×            |
| Pointer                             | Global pointer            | △            |
|                                     | Local pointer             | ×            |

\*1 The following data types cannot be used.

Timer, retentive timer, counter, long timer, long retentive timer, and long counter

#### Point

- Program a function name as a label in a function to set a return value of the function. Setting function names as labels is not necessary. The data type set in "Result Type" in the properties of the function can be used.

## Labels defined by a function

The labels defined by a function are assigned in the temporary areas of the storage-target memory during execution of the function, and the areas are freed after the processing completes.

**Ex.**

When calling FUN1 and FUN2 from the main program, and calling FUN3 by FUN1 (① to ⑦ indicate the execution flow (order).)

The following figure shows the label assignments while the above functions are being executed.

The class of labels that can be defined in the function are VAR, VAR\_CONSTANT, VAR\_INPUT, and VAR\_OUTPUT.

### Point

The label to be defined by a function must be initialized by a program before the first access because the label value will be undefined.

## 2.3 Function Blocks (FB)

A function block is a POU called and executed by program blocks and other function blocks.

Unlike a function, a function block does not have a return value.

A function block can hold values in variables and thus can hold input states and processing results.

A function block uses the value it holds for the next processing and therefore it does not always output the same result even with the same input value.

Ladder program

FBD/LD program

- (1) Instance name
- (2) Function block name
- (3) Output variable
- (4) Input variable

A function block needs to be instantiated to be used in programs.

Page 69 Instances

### Point

For details on module function blocks, refer to the following.

Function Block Reference for the module used

## Operation overview

### ■ Subroutine type function blocks

The program of a subroutine type function block is stored in the FB file and called by the calling source program when executed.

#### Ex.

When calling FB1\_a and FB2\_a from the main program, calling FB3\_a by FB1\_a, and calling FB3\_b by FB2\_a (Nested three times)

① to ⑨ indicate the execution flow (order).

Up to 32 subroutine type function blocks and functions in total can be nested.

## Input variables, output variables, and input/output variables

Input variables, output variables, and input/output variables need to be defined in function blocks.

A function block can output multiple operation results. It can also be set not to output operation results.

- (1) The operation result(s) is output.
- (2) No operation result is output.

Input variables are set in the VAR\_INPUT class, output variables are set in the VAR\_OUTPUT class and VAR\_OUTPUT\_RETAIN class, and input/output variables are set in the VAR\_IN\_OUT class.

## Internal variables

Function blocks use internal variables. For each instance of a function block, labels are assigned to the different areas. Even though the same label names are used, different states are held for each instance.

**Ex.**

The above function block starts counting when the input variables turn on and turns on the output variable when the current value held in the internal variable reaches the set value. Even though the same function block is used, the output timings differ because the instances A and B hold different states.

Internal variables are set in the VAR, VAR\_CONSTANT and VAR\_RETAIN class.

## External variables and public variables

Function blocks can use external variables (global label) and public variables.

Public variables are set in the VAR\_PUBLIC and VAR\_PUBLIC\_RETAIN class.

## Instances

### ■Instances

An instance is a label assigned to realize a function block definition. Multiple instances can be created from one function block definition.

An instance consists of the following items.

| Item                   | Description                                                                          |
|------------------------|--------------------------------------------------------------------------------------|
| Local label area       | Used to assign the local label of the function block.                                |
| Local latch label area | Used to assign the latch attribute local label of the function block.                |
| Signal flow area       | Used to assign the signal flow for the instruction in the function block definition. |

**Ex.**

#### Structure of instance

For the local label area and local latch label area, since the label area is secured in units of four words, three-words (padding size) are secured in the above example.

Each area has a reserved area. The reserved area is used to add or change instances of the function block or instructions that refer to local labels or the signal flow memory with the label assignment intact even when the program is converted or changed online.

If the area of the target data type to be added or changed cannot be secured, all programs are required to be converted, or the program is required to be converted and changed online.

**Ex.**

Structure of instance for nested function block (when reserved area of FB2 is changed)

When an FB nests another FB as shown above, the FB instance declared as a local label is secured outside the instance area of the declared source. Also, an area (6 words) for use by the system is secured in the local label area of the declared source. When an FB type local label is added or changed in FB1 of the above figure, the capacity for system use (6 words) is required for the FB1 local label area, and the capacity for the FB2 instance area (capacity for each of the local label area, local latch area, and signal flow area) is required for the instance area of the program that becomes the declared source of FB1. To add or change local labels or FB instances with the assignment intact (without converting all programs), secure the capacity required to add or change them in the reserved area, or convert and change the program online. For the reserved area setting method, refer to the following.

📖 GX Works3 Operating Manual

## ■Creating instances

A function block needs to be instantiated to be used in programs.

By creating instances, a function block can be called and executed by a program block or another function block.

Declare instances with global labels or local labels.

| Label type                | Instance type | Class      |
|---------------------------|---------------|------------|
| Global label              | Global FB     | VAR_GLOBAL |
| Local label <sup>*1</sup> | Local FB      | VAR        |

<sup>\*1</sup> Local labels can be declared as the local labels of a program block or function block. Local labels cannot be declared in a function. Same function blocks can be instantiated with different names in a single POU.

(1) Same instances use the same internal variables.

(2) Different instances use different internal variables.

## ■Capacity of instance

The capacity of each data area of an instance should be calculated as follows.

- Capacity of local label area

Capacity of local label area of instance = Total capacity of data of local labels (except the ones with latch attribute) + Capacity of reserved area

| Item                                                            | Description                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Capacity of local labels (except the ones with latch attribute) | Total capacity of the data used for local labels.<br>The capacity of areas to be used differs depending on the memory assignment of labels. For details on memory assignment of labels, refer to the following.<br> GX Works3 Operating Manual |
| Capacity of reserved area                                       | 48 words in default. Set the capacity in units of 4 words.                                                                                                                                                                                                                                                                      |

- Capacity of local latch label area

Capacity of local latch label area of instances = Total capacity of data of local labels with latch attribute + Capacity of reserved area

| Item                                     | Description                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Capacity of latch attribute local labels | Total capacity of the data used for latch attribute local labels.<br>The capacity of areas to be used differs depending on the memory assignment of labels. For details on memory assignment of labels, refer to the following.<br> GX Works3 Operating Manual |
| Capacity of reserved area                | 16 words in default. Set the capacity in units of 4 words.                                                                                                                                                                                                                                                                                      |

- Capacity of signal flow area

Signal flow area capacity of the instance = Total signal flow area used for the instruction in FB definition + Reserved area capacity

| Item                         | Description                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------|
| Capacity of signal flow area | Total capacity of the signal flow area for the instruction in the function block definition |
| Capacity of reserved area    | 4 words in default. Set the capacity in units of 1 words.                                   |

### Point

Set enough reserved area capacity for the data (such as local labels or the signal flow memory) that is expected to be added or changed when the program is changed online. For the setting method, refer to the following.

 GX Works3 Operating Manual

If some structure labels are included in the local labels of the function block definition, addition or change exceeding the estimated area capacity cannot be made when the program is converted and changed online, and all programs are required to be converted. For more details, check the user's manual for the controller used.

In the following function blocks, the controller memory can be efficiently used by setting smaller value than default to the reserved area.

- Debugged subroutine type function block where no local label is added or changed and no program is changed
- Subroutine type function block that declares many instances

## Setting initial values

### Initial values of local label

For the local label of a function block, an initial value can be set for each function block definition or instance. The local label classes where initial values can be set are VAR, VAR\_RETAIN, VAR\_INPUT, VAR\_OUTPUT, VAR\_OUTPUT\_RETAIN, VAR\_PUBLIC, and VAR\_PUBLIC\_RETAIN.

### Initial values of instance

The following table summarizes the types of the initial values of instances.

| Type                        | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default initial value       | <p>An initial value predefined for each data type. If an initial value is not set for the local label of a function block, the default initial value will be used.</p> <p>(1) The initial values have not been set for the local labels in the FB1 definition.<br/>(2) The default initial values are used.</p>                                                                       |
| FB definition initial value | <p>An initial value that is set when the local label of a function block is defined. If this initial value has been set, the same definition initial value will be used for all the instances.</p> <p>(1) The initial values have been set for the local labels in the FB1 definition.<br/>(2) All the instances of FB1 will be initialized by the same definition initial value.</p> |
| Instance initial value      | <p>An initial value that is set for an instance included in the global label and program block local label definition.</p> <p>(1) The initial value can be set for each instance in the FB1 definition.</p>                                                                                                                                                                           |

For function blocks, both the FB definition and instance initial values can be set.

If both initial values are set, the initial values used will take the following priority.

| Priority  | Type                        |
|-----------|-----------------------------|
| High<br>↑ | Instance initial value      |
| ↓         | FB definition initial value |
| Low       | Default initial value       |

### Point

If two instances of a function block for which the FB definition initial value has been set are created and the instance initial value is set for only one of them, the FB definition initial value will be used for the instance for which the instance initial value has not been set and the instance initial value will be used for the other.

(1) When the instance initial value is not set, the FB definition initial value will be used.

(2) When the instance initial value is set, it will be used.

## ■Example

The following figure shows an example where the function block initial values are used.

## EN and ENO

In the same way as a function, EN (enable input) and ENO (enable output) can also be appended to a function block to control execution processing. (  Page 63 EN and ENO)

When the instance of a function to which EN/ENO has been appended is called, an actual argument must be assigned to EN.

For the execution conditions on the motion control function blocks, refer to the following.

 Page 1431 Execution command (Execute) type/Enable (Enable) type

## Creating programs

The program of a function block can be created by using the engineering tool.

 [Navigation window] ⇒ [FB/FUN] ⇒ Right-click ⇒ [Add New Data]  
Select "Function Block" for "Data Type" in "Basic Setting".

The created program is stored in the FB file.

 [CPU Parameter] ⇒ [Program Setting] ⇒ [FB/FUN File Setting]

Up to 64 created programs can be stored in one FB file.

For details on program creation, refer to the following.

| Item                                                       | Reference                                                                                                               |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| How to create function blocks                              |  IGX Works3 Operating Manual           |
| Number of FB/FUN files that can be written to a controller |  User's manual for the controller used |

### ■Types of program

There are two types of function blocks and the program of each function block type is stored in different ways.

- Subroutine type function block

For details, refer to the following.

 Page 67 Operation overview

The above cannot be selected for module function blocks, standard functions, standard function blocks, and motion control function blocks.

### ■Inherent property setting

The following items can be set when a program of a function block is created. ( IGX Works3 Operating Manual)

| Item                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use MC/MCR to Control EN | For "Yes", the MC/MCR instructions are used to control EN. For "No", the CJ instruction is used to control EN. Select "Yes" when instructions executed at the rising edge or falling edge are used in an FB. The operations of a timer/counter and the OUT instruction used in an FB differ depending on the selected item. For details, refer to the following.<br> Page 85 Operations of when the MC/MCR instructions are used to control EN |
| Use EN/ENO               | For "Yes", a function block with EN/ENO is created, and EN/ENO labels can be used in a program without registering as local labels. For "No", a function block without EN/ENO is created. For details on EN/ENO, refer to the following.<br> Page 75 EN and ENO                                                                                                                                                                                |

### ■Applicable devices and labels

The following table lists the devices and labels that can be used by function block programs.

○: Applicable, △: Applicable only in instructions (Cannot be used to indicate the program step.), ×: Not applicable

| Type of device/label                |                           | Availability |
|-------------------------------------|---------------------------|--------------|
| Label (other than the pointer type) | Global label              | ○            |
|                                     | Local label               | ○            |
| Label (pointer type)                | Pointer type global label | △            |
|                                     | Pointer type local label  | ○            |
| Device                              | Global device             | ○            |
|                                     | Local device              | ×            |
| Pointer                             | Global pointer            | △            |
|                                     | Local pointer             | ×            |

## 2.4 Precautions

### When a function is used

#### Pointer

The local pointer and pointer type global labels cannot be used.

### When a function block is used

#### Pointer

The local pointer cannot be used.

#### When the index register is used

When the index register is used in the function block program, ladder programs for saving and returning the index register values are required to protect the values.

Setting the index register data to 0 when saving can prevent an error that could be caused by an index modification validity check. (Whether the device number exceeds the device range or not is checked.)

#### Ex.

A program that saves the values in the index register Z1 and Z2 before the program execution and returns the saved values after the program execution

Specifying the start I/O number of intelligent function module

When accessing the buffer memory or I/O signals of the intelligent function module, specify the start I/O number using the index register.

By receiving the start I/O number as an input variable, the same function block can be shared in multiple intelligent function modules without changing the start I/O number.

Ex.

To access the I/O signals of the intelligent function module  
Use the index register.

[Sequence program]

[FB program]

Ex.

To access the buffer memory of the intelligent function module

- 1 Input the start I/O number of the target intelligent function module in the index register.
- 2 Shift the four bits in the value to the right by using the SFR instruction, or use the quotient obtained by dividing the value by 16.

## Copying a macro type function block

When using multiple macro type function blocks, drag and drop them from the Element Selection window.

When the FB compilation method copies a macro type function block on the program editor, the copied function block is changed to a subroutine type function block.

When copying a module FB or FB library, check the reference manual of the function block to be used, and check whether the FB compilation method indicates subroutine type before using it.

### Point

A macro type function block is a type of function block used in a module FB or FB library. It cannot be defined by users.

The program is loaded by a calling source program along the execution flow. At the time of program execution, the loaded program is executed in the same way as the main program.

## Calling a macro type function block

Call each instance of a macro type function block as a pointer destination by using a pointer type label only once in a project. If the same instance of a macro type function block as a pointer destination using a pointer type label is called multiple times, a conversion error occurs.

## Restrictions for module function blocks

The following describes the restrictions for the use of module function blocks.

- Do not turn off the contact of the MC instruction when calling a module function block between the MC instruction and MCR instruction.
- Do not perform the jump processing that prevents module function blocks from being called by the CJ instruction, SCJ instruction, and JMP instruction.
- Execute a subroutine program every scan when calling a module function block in the subroutine program. Do not perform the non-execution processing of a subroutine program by using the FCALL(P) instruction, EFCALL(P) instruction, or XCALL instruction.
- Do not call a module function block in an interrupt program, an initial execution type program, a fixed scan execution type program, or an event execution type program.
- Do not call a module function block between the FOR and NEXT instructions, in the inline ST, or the control syntax of the structured text language (IF statement, FOR statement, and CASE statement.)
- Specifying modified devices for input and output arguments of some module FBs may cause an error. To specify modified devices for input and output arguments of a module FB, describe a processing so that the value is transferred after the module FB is called.

## Changing operating parameters of module function blocks

Operating parameters (external variables) other than input and output labels of module function blocks can be changed on the label setting window by using the engineering tool.

- When the instance of a module function block is set to local label, change the parameters on the "Local Label Setting" window.

🔗 [Navigation Window] ⇒ [Program] ⇒ execution type ⇒ program file ⇒ program block ⇒ [Local Label]

- When the instance of a module function block is set to global label, change the parameters on the "Global Label Setting" window.

🔗 [Navigation Window] ⇒ [Label] ⇒ [Global Label]

**Ex.**

Local Label Setting window

| Label Name                             | Data Type                             | Comment |
|----------------------------------------|---------------------------------------|---------|
| 1 M_RCPU_Maynchronization_Delay1OUT_00 | M+RCPU_Maynchronization_Delay1OUT_00A |         |
| 2 M_RJ71GF11_DeviceRead_00B_1          | M+RJ71GF11_DeviceRead_00B             |         |
| 3                                      |                                       |         |

| Class      | Label Name           | Data Type                                  | Initial Value | Comment |
|------------|----------------------|--------------------------------------------|---------------|---------|
| VAR_INPUT  | i_bEN                | Bit                                        |               |         |
| VAR_INPUT  | i_stModule           | M+RJ71GF11                                 |               |         |
| VAR_INPUT  | i_u2TargetAddress    | Word [Unsigned]/Bit String [16-bit][0..1]  |               |         |
| VAR_INPUT  | i_uDataLength        | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_INPUT  | i_s32TargetDevice    | String(32)                                 |               |         |
| VAR_INPUT  | i_uChannel           | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_OUTPUT | o_bENO               | Bit                                        |               |         |
| VAR_OUTPUT | o_bOK                | Bit                                        |               |         |
| VAR_OUTPUT | o_bErr               | Bit                                        |               |         |
| VAR_OUTPUT | o_uErrId             | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_OUTPUT | o_uReadData          | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbl_uCPU_Type        | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbl_uResendCountMax  | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbl_uTimeUnit        | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbl_uMonitorTime     | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbl_bStationSpecific | Bit                                        |               |         |
| VAR_PUBLIC | pbo_uResendCount     | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbo_uErrTime         | Word [Unsigned]/Bit String [16-bit][0..3]  |               |         |
| VAR_PUBLIC | pbo_uErrNetworkNo    | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR_PUBLIC | pbo_uErrStationNo    | Word [Unsigned]/Bit String [16-bit]        |               |         |
| VAR        | u18ControlData       | Word [Unsigned]/Bit String [16-bit][0..17] |               |         |
| VAR        | b_Start              | Bit                                        |               |         |
| VAR        | b2Comp               | Bit(0..1)                                  |               |         |

Set operating parameters in the "Initial Value" field.

## Operations of when the MC/MCR instructions are used to control EN

The following table lists operations of instructions, devices, and labels used in a function block when "Use MC/MCR to Control EN" is enabled in the inherent property setting of the function block.

| Instruction/device/label used in a function block                                                                         | Operation of Instruction/device/label used in a function block                                         |                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
|                                                                                                                           | When "Yes" is selected for "Use MC/MCR to Control EN"                                                  | When "No" is selected for "Use MC/MCR to Control EN"                                                          |
| Instructions executed at the rising edge or falling edge (PLS, instructions for conversion to pulses (□P) <sup>*1</sup> ) | The next time EN is turned on, the instruction is executed if the condition contact is TRUE.           | The next time EN is turned on, the instruction may not be executed even though the condition contact is TRUE. |
| Timer (low-speed/high-speed), long timer                                                                                  | The count value becomes 0 and the both coil and contact turn off.                                      | The state of devices remains unchanged.                                                                       |
| Retentive timer (low-speed/high-speed), long retentive timer, counter, long counter                                       | The coil turns off, but the current count value and the current state of the contact remain unchanged. | The state of devices remains unchanged.                                                                       |
| Devices specified as the device part of the OUT instruction                                                               | The devices are forcibly turned off.                                                                   | The state of devices remains unchanged.                                                                       |

\*1 Instructions specified in the coil side apply.

### Restriction

When "Yes" is selected for "Use MC/MCR to Control EN", do not use the MC/MCR instructions while the function block is being executed. If the MC/MCR instructions are used, the EN control may not operate properly.

## Instructions executed at the rising/falling edge

The following describes operations of instructions executed at the rising/falling edge.

**Ex.**

A subroutine-type FB using an instruction executed at the rising edge

### ■When "Yes" is selected for "Use MC/MCR to Control EN"

When EN is turned on, the instruction is executed if the condition contact is TRUE ((1) in the following figure).

Sc: Scan

- ① EN is turned on. (User operation)
- ② IN is turned on. (User operation)
- ③ The MOV instruction is executed. (Controller operation)
- ④ EN is turned off. (User operation)
- ⑤ The MOV instruction is executed. (Controller operation)

### ■When "No" is selected for "Use MC/MCR to Control EN"

When EN is turned off, operations of the instruction differ depending on the condition contact status ((1) in the following figure).

Sc: Scan

- ① EN is turned on. (User operation)
- ② IN is turned on. (User operation)
- ③ The MOV instruction is executed. (Controller operation)
- ④ EN is turned off. (User operation)
- ⑤ The MOV instruction is executed when the condition contact is FALSE immediately before EN is turned off at ④. (Controller operation) (The MOV instruction is not executed when the condition contact is TRUE immediately before EN is turned off at ④.)

## Timer (low-speed/high-speed) and long timer

The following describes operations of the timer (low-speed/high-speed) and long timer.

### Ex.

A subroutine-type FB using a low-speed timer

### ■When "Yes" is selected for "Use MC/MCR to Control EN"

The count value becomes 0 ((1) in the following figure). The coil turns off ((2) in the following figure).

Sc: Scan

T0(Count): T0 (count value)

T0(Coil): T0 (coil)

① EN is turned off. (User operation)

② The coil turns off and the timer value and the count value are cleared. (Controller operation)

### ■When "No" is selected for "Use MC/MCR to Control EN"

The current count value and the current state of the coil remain unchanged. ((1) in the following figure).

Sc: Scan

T0(Count): T0 (count value)

T0(Coil): T0 (coil)

① EN is turned off. (User operation)

② The values remain unchanged. (Controller operation)

## Retentive timer (low-/high-speed), long retentive timer, counter, and long counter

The following describes operations of the retentive timer (low-speed/high-speed), long retentive timer, counter, and long counter.

**Ex.**

A subroutine-type FB using a low-speed retentive timer

### ■When "Yes" is selected for "Use MC/MCR to Control EN"

The current count value remain unchanged. ((1) in the following figure). The coil turns off ((2) in the following figure).

Sc: Scan

ST0(Count): T0 (count value)

ST0(Coil): T0 (coil)

① EN is turned off. (User operation)

② The coil turns off, but the current count value and the current state of the contact remain unchanged. (Controller operation)

### ■When "No" is selected for "Use MC/MCR to Control EN"

The current count value and the current state of the coil remain unchanged. ((1) in the following figure).

Sc: Scan

ST0(Count): T0 (count value)

ST0(Coil): T0 (coil)

① EN is turned off. (User operation)

② The values remain unchanged. (Controller operation)

## Devices specified as the device part of the OUT instruction

The following describes operations of devices specified as the device part of the OUT instruction.

**Ex.**

A subroutine-type FB using M0 for the device part of the OUT instruction.

### ■When "Yes" is selected for "Use MC/MCR to Control EN"

M0 is forcibly turned off ((1) in the following figure).

Sc: Scan

① EN is turned off. (User operation)

② The coil turns off. (Controller operation)

### ■When "No" is selected for "Use MC/MCR to Control EN"

The current state of M0 remains unchanged ((1) in the following figure).

Sc: Scan

① EN is turned off. (User operation)

② The state of coil remains unchanged. (Controller operation)

# 3 LADDER DIAGRAM

Ladder diagram is a programming language used to describe sequence control. Each ladder consists of contacts and coils and represents logical operations consisting of AND/OR in combinations of series and parallel.

This chapter describes the operation and specifications of the ladder diagram. For the operation method of the engineering tool for creating a ladder program, refer to the following.

GX Works3 Operating Manual

## 3.1 Configuration

The following are the programs written in ladder diagram.

- (1) Ladder program consisting of a contact and a coil
- (2) Ladder program configured in series
- (3) Ladder program configured in parallel
- (4) Ladder program using an instruction
- (5) Ladder program using a standard function/function block

## Ladder symbols

The following table lists the ladder symbols that can be used for programming in ladder diagram.

| Item                                          |  | Description                                                                                                                          |
|-----------------------------------------------|--|--------------------------------------------------------------------------------------------------------------------------------------|
| Normally open contact                         |  | Energized when the specified device or label is on.                                                                                  |
| Normally closed contact                       |  | Energized when the specified device or label is off.                                                                                 |
| Rising edge pulse                             |  | Energized on the rising edge (off to on) of the specified device or label.                                                           |
| Falling edge pulse                            |  | Energized on the falling edge (on to off) of the specified device or label.                                                          |
| Negated rising edge pulse                     |  | Energized when the specified device or label is off, on, or on the falling edge (on to off).                                         |
| Negated falling edge pulse                    |  | Energized when the specified device or label is off, on, or on the rising edge (off to on).                                          |
| Operation result rising edge pulse conversion |  | Energized on the rising edge (off to on) of the operation result. De-energized while the operation result is not on the rising edge. |

| Item                                           |                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operation result falling edge pulse conversion |   | Energized on the falling edge (on to off) of the operation result. De-energized while the operation result is not on the falling edge.                                                                                                                                                                                                                                                   |
| Operation result inversion                     |   | Inverts the previous operation results.                                                                                                                                                                                                                                                                                                                                                  |
| Coil                                           |   | Outputs the operation result to the specified device or label.                                                                                                                                                                                                                                                                                                                           |
| Instruction                                    |   | Executes the instruction specified in "[ ]".                                                                                                                                                                                                                                                                                                                                             |
| Loopback                                       |   | When the number of contacts that can be created on a single ladder line is exceeded, the ladder is looped back with loopback source and destination symbols created on it.                                                                                                                                                                                                               |
| Function                                       |   | Executes a function. <ul style="list-style-type: none"> <li>• How to create functions (GX Works3 Operating Manual)</li> <li>• Standard function (Page 183 Standard Functions)</li> </ul>                                                                                                                                                                                                 |
| Function block                                 |  | Executes a function block. <ul style="list-style-type: none"> <li>• How to create function blocks (GX Works3 Operating Manual)</li> <li>• Standard function block (Page 194 Standard Function Blocks)</li> <li>• Motion control function block (Page 196 MOTION CONTROL FUNCTION BLOCK LIST)</li> <li>• Module function blocks (Function Block Reference for the module used)</li> </ul> |

## Program execution order

The program is executed in order of the following numbers.

When the above program is executed, Y41 and Y42 turn on while X41 to X44 turn on or off as shown below.

# Precautions for using a function block in ladder diagram

## Precautions for directly connecting to an FB instance from the left rail

When EN and input variables (bit type) are directly connected to the left rail in the input circuit of the FB instance, the on/off state does not change.

To change the on/off states of EN and the input variables (bit type), use a contact or an instruction equivalent to the contact.

## 3.2 Inline ST

The inline ST is the function used to create an inline ST box that displays an ST program in the cell of the instruction corresponding to a coil in the ladder editor, and edit and monitor it.

This function enables to create numerical operations and string processing easily in ladder programs.

- Program that does not use the inline ST

- Program that uses the inline ST

## Specifications

For the specifications of the ST program described to the inline ST, refer to the specifications of the ST language.

Page 92 STRUCTURED TEXT LANGUAGE

## Precautions

- Only one inline ST can be created on a single line of a ladder program.
- Both a function/function block and inline ST box cannot be used on a single line of a ladder program.
- Creating an inline ST box at the position of an instruction corresponding to a contact creates an inline ST box at the position of an instruction corresponding to a coil.
- Up to 20000 characters can be input in the inline ST. (A newline is counted as two characters.)
- Using a RETURN statement in the inline ST causes the processing in the inline ST box to end, instead of the processing of the program block.
- When the inline ST in the program of a function is used, no function block can be called from the inline ST.
- The inline ST uses the CJ instruction in conversion to control the operation of a program. When the contact of the inline ST is off, the processing in the inline ST is not executed by the CJ instruction. Thus, for example, the device that turned on by the assignment statement in the inline ST holds its output status even when the inline ST is not executed. For details on the CJ instruction, refer to the following.

 Page 534 CJ, SCJ, JMP

- In the inline ST, OUT, OUTH, or other instructions which refer to the previous execution status of the signal flow memory cannot be used.

 User's manual for the controller used

## 3.3 Statements and Notes

Statements and notes can be used in ladder programs.

### Statements

A statement is used to add a comment to a ladder block. Adding a comment makes it easy to understand the flow of processing.

There are three types of statements: line statement, P statement, and I statement.

The line statement can be displayed in the tree of the navigation window.

#### ■Line statement

This type of statement adds a comment to the entire ladder block.

#### ■P statement

This type of statement adds a comment to a pointer device.

#### ■I statement

This type of statement adds a comment to an interrupt pointer device.

### Notes

A note is used to add a comment to a coil and instruction in a program.

Adding a comment makes it easy to understand the contents of the coil and instruction.

### Categories of statements and notes

Statements and notes are classified into two categories: "In PLC" and "In Peripheral".

| Category      | Type                                                                                                                        | Description                                                                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| In PLC        | <ul style="list-style-type: none"><li>• Line statement</li><li>• P statement</li><li>• I statement</li><li>• Note</li></ul> | Strings of the description are not embedded in the program during conversion, but they are saved as attached information of the program.<br>One line uses one step.                                                               |
| In Peripheral | <ul style="list-style-type: none"><li>• Line statement</li><li>• P statement</li><li>• I statement</li><li>• Note</li></ul> | Strings of the description are not embedded in the program, but they are saved as attached information of the program.<br>One line uses one step.<br>A text that has been entered is automatically preceded by an asterisk "***". |

# 4

## STRUCTURED TEXT LANGUAGE

ST language is defined by International Standard IEC 61131-3 that defines the logic description system. ST language is a text language with a similar grammatical structure to C. This language is suitable for programming complicated processing that cannot be easily described by ladder diagram.

### Point

This chapter describes the operation and specifications of the structured text language. For the operation method of the engineering tool for creating an ST program, refer to the following.

 GX Works3 Operating Manual

The ST language supports control syntax, operational expressions, function blocks (FB), and functions (FUN), and can describe them as shown below.

### Ex.

Control syntax such as selective branches by conditional statements and iteration statements

(\*Control conveyors, Line A to C.\*)

```
CASE Line OF
  1:
    Start_switch := TRUE; (*The conveyor starts.*)
  2:
    Start_switch := FALSE; (*The conveyor stops.*)
  3:
    Start_switch := TRUE; (*The conveyor stops with an alarm.*)
ELSE
  Alarm_lamp := TRUE;
END_CASE;
IF Start_switch = TRUE THEN (*The conveyor starts and performs processing 100 times.*)
  FOR Count := 0 TO 100 BY 1 DO
    Count_No. := Count_No + 1;
  END_FOR;
END_IF;
```

### Ex.

Expression using operators (\*, /, +, -, <, >, =)

```
D0 := D1 * D2 + D3 / D4 - D5 ;
IF D0 > D10 THEN
  D0 := D10;
END_IF;
```

### Ex.

Calling function blocks that have been defined

```
//FB data name: LINE1_FB
//Input variable: I_Test
//Output variable: O_Test
//Input/output variable: IO_Test
//FB label name: FB1
FB1(I_Test:= D0 , O_Test => D1 ,IO_Test:= D100 );
```

### Ex.

Calling standard functions

```
(*Convert BOOL data type to INT/DINT data type.*)
wLabel2 := BOOL_TO_INT (bLabel1);
```

# 4.1 Configuration

Programs written in ST language consist of operators and control statements.

Each statement must end with a semicolon ";".

Spaces, tabs, and line feeds can be inserted between an operator and data.

Comments can be inserted into a program. Enclose a comment statement with "(\*" and "\*)".

## Program components

An ST program consists of the following components.

| Item          | Example                                  | Reference                   |
|---------------|------------------------------------------|-----------------------------|
| Delimiter     | ;, (, )                                  | Page 94 Delimiter           |
| Operator      | +, -, <, >, =                            | Page 94 Operators           |
| Reserved word | Control statement                        | IF, CASE, WHILE, RETURN     |
|               | Device                                   | X40, Y50, M100, ZR0         |
|               | Data type                                | BOOL, DWORD                 |
|               | Standard function                        | ADD, REAL_TO_STRING_E       |
| Constant      | 123, "abc"                               | Page 106 Constants          |
| Label         | Switch_A                                 | Page 107 Labels and devices |
| Comment       | (*Turn on.*)                             | Page 109 Comments           |
| Other symbols | One-byte space, line feed code, TAB code | —                           |

- Write delimiters, operators, and reserved words in one-byte characters.
- For details on the reserved words, refer to the following.

GX Works3 Operating Manual

# Delimiter

ST language supports the following delimiters to make the program structure clear.

| Symbol                    | Description                                          |
|---------------------------|------------------------------------------------------|
| ()                        | Parenthesized expression                             |
| []                        | Specification of array element number                |
| . (period)                | Specification of structure or function block members |
| , (comma)                 | Argument separation                                  |
| : (colon)                 | Device type specifier or CASE statement delimiter    |
| ; (semicolon)             | Termination of statement                             |
| " (double quotation mark) | Notation of Unicode string                           |
| ' (single quotation mark) | Notation of string (ASCII, Shift JIS)                |
| .. (two periods)          | Specification of integer range                       |

# Operators

The following table lists the operators, applicable data types, and operation result data types used in ST programs.

| Operator             | Applicable data type                                | Operation result type |
|----------------------|-----------------------------------------------------|-----------------------|
| *, /, +, -           | ANY_NUM <sup>*1</sup>                               | ANY_NUM               |
| <, >, <=, >=, =, <>  | ANY_ELEMENTARY <sup>*2</sup>                        | Bit                   |
| MOD                  | ANY_INT                                             | ANY_INT               |
| AND, &, XOR, OR, NOT | ANY_BIT                                             | ANY_BIT               |
| **                   | ANY_REAL (base)<br>ANY_NUM (exponent) <sup>*1</sup> | ANY_REAL              |

\*1 Notation of constants with "WORD#" or "DWORD#" cannot be specified. (Page 106 Notation of constants)

\*2 WSTRING data type Unicode string cannot be specified.

The following table lists the operators in descending order of priority.

| Operator     | Description              | Example           | Priority |
|--------------|--------------------------|-------------------|----------|
| ()           | Parenthesized expression | (2+3)*(4+5)       | 1        |
| Function ()  | Function call expression | CONCAT('AB','CD') | 2        |
| -            | Sign inversion           | -10               | 3        |
| NOT          | Bit type complement      | NOT TRUE          |          |
| **           | Exponentiation           | 3.0**4            | 4        |
| *            | Multiplication           | 10*20             | 5        |
| /            | Division                 | 20/10             |          |
| MOD          | Remainder                | 17 MOD 10         |          |
| +            | Addition                 | 1.4+2.5           | 6        |
| -            | Subtraction              | 3-2               |          |
| <, >, <=, >= | Comparison               | 10>20             | 7        |
| =            | Equality                 | T#26h=T#1d2h      | 8        |
| <>           | Inequality               | 8#15<>13          |          |
| &, AND       | AND operation            | TRUE AND FALSE    | 9        |
| XOR          | XOR operation            | TRUE XOR FALSE    | 10       |
| OR           | OR operation             | TRUE OR FALSE     | 11       |

- If one expression includes multiple operators with the same priority, operation is performed in order from the leftmost operator.
- Up to 1024 operators can be used in a single expression.

# Instruction

This section describes instructions used in the ST program.

```
bResult := BMOV( TRUE, wValue0, 1, wValue1);
```

(1) Specify a return value.

(The example shown above indicates that ENO is assigned to bResult. For instructions, the description of the return value can be omitted.)

(2) Specify an instruction name.

(3) Specify instruction arguments.

## Omitting the specification of arguments in EN for instructions

For instructions, the specification of arguments in EN can be omitted.

In that case, the following program can be described as operation is performed assuming that TRUE is assigned to EN.

```
//Before omission
MOV(TRUE, SrcLabel, DstLabel);
//After omission
MOV(SrcLabel, DstLabel);
```

For cases other than instructions (such as standard functions), EN cannot be omitted.

# Control statements

The following table lists the control statements that can be used in ST programs.

| Item                         | Description                                 | Reference                             |
|------------------------------|---------------------------------------------|---------------------------------------|
| Assignment statement         | Assignment statement                        | Page 96 Assignment statement          |
| Subprogram control statement | Function block and function call statements | Page 98 Subprogram control statements |
|                              | RETURN statement                            |                                       |
| Select statement             | IF statement (IF THEN, IF ELSE, IF ELSIF)   | Page 99 Select statements             |
|                              | CASE statement                              |                                       |
| Iteration statement          | FOR statement                               | Page 99 Iteration statements          |
|                              | WHILE statement                             |                                       |
|                              | REPEAT statement                            |                                       |
|                              | EXIT statement                              |                                       |

Write control statements in one-byte characters.

## Assignment statement

| Format                     | Description                                                                                                                                                                                                 | Example                |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <Left side>:=<Right side>; | This statement assigns the result of the right side expression to the label or device on the left side.<br>The data types of the result of the right side expression and the left side need to be the same. | intV1:=0;<br>intV2:=2; |

When using an array type label and structure label, note the data types of the left side and right side of the assignment statement.

For array type labels, the data type and the number of elements need to be the same between the left and right sides. When using array type labels, do not specify elements.

**Ex.**

intAry1:=intAry2;

For structure labels, the data type of the structure needs to be the same between the left and right sides.

**Ex.**

dutVar1:=dutVar2;

When the right side is the function call expression, the return value of the function is assigned to the left side. The following table lists examples to assign the return value to the label.

| Function                                            | Example                                                                                                                                  |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Having one input variable (example: ABS)            | Output1 := ABS( Input1 );                                                                                                                |
| Having three input variables (example: MAX)         | Output1 := MAX( Input1 , Input2 , Input3 );                                                                                              |
| Having EN/ENO (standard functions) (example: MAX_E) | Output1 := MAX_E( boolEN , boolENO , Input1 , Input2 , Input3 );                                                                         |
| Except for standard functions (example: MOV)        | boolENO := MOV( boolEN , Input1 , Output1 );<br>(The execution result of the function is ENO, and the first argument (variable1) is EN.) |

## ■ Automatic conversion of data type

When assignment or arithmetic operational expressions between different data types is described in ST language, one data type may be converted automatically.

### Ex.

Example of automatic conversion

```
dintLabel1 := intLabel1;
// Assignment statement: Automatically convert the INT type variable (intLabel1) to a DINT type variable, and assign it to the DINT type variable (dintLabel1).

dintLabel1 := dintLabel2 + intLabel1;
// Arithmetic operational expression: Automatically convert the INT type variable (intLabel1) to a DINT type variable, and perform addition in DINT type.

DMOV(TRUE, wordLabel1, dwordLabel1);
// Instruction, function, and function block call statement: Automatically convert the WORD type input argument (wordLabel1) to a DWORD type variable, and transfer the data.
```

Type conversion is performed in assignment statements, VAR\_INPUT part where input argument is passed to function blocks and functions (including instruction, standard functions, and standard function blocks), and arithmetic operational expressions.

To prevent data from being lost during type conversion, conversion is performed only from a smaller size data type to a larger size data type. Type conversion is performed for the following data types among the primitive data types.

| Data type                                   | Description                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Word [signed]                               | When the data type is converted to the double word [signed], the value is automatically sign extended.<br>When the data type is converted to the single-precision real number or double-precision real number, the value is automatically converted to the same value as the integer before conversion.*1                                                  |
| Word [unsigned]/bit string [16 bits]        | When the data type is converted to the double word [unsigned]/bit string [32 bits] or double word [signed], the value is automatically zero extended.*2<br>When the data type is converted to the single-precision real number or double-precision real number, the value is automatically converted to the same value as the integer before conversion.*1 |
| Double word [signed]                        | When the data type is converted to the double-precision real number, the value is automatically converted to the same value as the integer before conversion.                                                                                                                                                                                              |
| Double word [unsigned]/bit string [32 bits] |                                                                                                                                                                                                                                                                                                                                                            |
| Single-precision real number                | When the data type is converted to the double-precision real number, the value is automatically converted to the same value.                                                                                                                                                                                                                               |

\*1 When 16-bit data (word [signed] or word [unsigned]/bit string [16 bits]) is passed to the input argument of which data type is ANY\_REAL, the data is automatically converted to single-precision real number.

\*2 When data (word [unsigned]/bit string [16 bits]) is passed to the input argument of which data type is ANY32, the data is automatically converted to double word [unsigned]/bit string [32 bits].

For the data types other than the above, use the type conversion functions.

Use the type conversion functions for the following conversions as well.

- Type conversion between integral data types with different signs
- Type conversion between data types both of which lose data

For the precautions on assignment of the arithmetic operation result, refer to the following.

📖 Page 101 When the result of an arithmetic operation is assigned

For the precautions on the use of devices, refer to the following.

📖 Page 108 When performing automatic conversion of data type with devices

## Subprogram control statements

### ■Function block call statement

| Format                                                                                                           | Description                                                                                                                                                                                       |
|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Instance name (input variable1:=variable1,...output variable1=>variable2,...);                                   | Enclose the assignment statements to the input and output variables in '()' after the instance name.<br>When using multiple variables, delimit individual assignment statements with a comma ','. |
| Instance name.input variable1:=variable1;<br>:<br>Instance name();<br>Variable2:=instance name.output variable1; | List the assignment statements to input and output arguments between function block call statements.                                                                                              |

The following table lists the symbols used in the arguments of the function block call statements and the expressions that can be assigned.

| Type                               | Description           | Symbol used | Assignable expression |
|------------------------------------|-----------------------|-------------|-----------------------|
| EN, VAR_INPUT                      | Input variable        | :=          | All expressions       |
| ENO, VAR_OUTPUT, VAR_OUTPUT_RETAIN | Output variable       | =>          | Only variables        |
| VAR_IN_OUT                         | Input/output variable | :=          | Only variables        |

The execution result of a function block is stored by specifying an output variable after the instance name with a period "." and assigning the result to the specified variable.

| Function block                                        | FB definition                                                                                                                                                          | Example                                                                                                  |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Having one input variable and one output variable     | FB name: FBADD<br>FB instance name: FBADD1<br>Input variable1: IN1<br>Output variable1: OUT1                                                                           | FBADD1(IN1:= Input1 );<br>Output1 := FBADD1.OUT1;                                                        |
| Having three input variables and two output variables | FB name: FBADD<br>FB instance name: FBADD1<br>Input variable1: IN1<br>Input variable2: IN2<br>Input variable3: IN3<br>Output variable1: OUT1<br>Output variable2: OUT2 | FBADD1(IN1:= Input1 ,IN2:= Input2 ,IN3:= Input3 );<br>Output1 := FBADD1.OUT1;<br>Output2 := FBADD1.OUT2; |

### ■Function call statement

Function without a return value, or includes VAR\_OUTPUT variable in parameters can be executed as a statement by adding ";" (semicolon) after the function call statement.

| Format                                   | Description                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Function name (variable1,variable2,...); | Enclose arguments in "()" following the function name.<br>When using multiple variables, delimit them with a comma ",". |

### ■RETURN statement

| Control statement | Format  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Example                             |
|-------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| ■RETURN           | RETURN; | The statement is used to terminate a program, function block, or function during operation.<br>When the RETURN statement is used in a program, control jumps to the step next to the last statement in the program.<br>When the RETURN statement is used in a function block, control returns from the function block.<br>When the RETURN statement is used in a function, control returns from the function.<br>A single RETURN statement uses one point of the pointer type label in the system. | IF bool1 THEN<br>RETURN;<br>END_IF; |

## Select statements

| Control statement | Format                                                                                                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                               | Example                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| ■IF THEN          | IF<boolean expression>THEN<br><statement...>;<br>END_IF;                                                                                                                                                              | The statement is executed if the boolean expression (conditional formula) is TRUE. The statement is not executed if the boolean expression is FALSE.<br><br>Any expression can be used for the boolean expression if it returns TRUE or FALSE as the boolean operation result of a single bit variable expression or a complicated expression including many variables.                                   | IF bool1 THEN<br>intV1 := intV1 + 1;<br>END_IF;                                                                                       |

## Precautions

### ■When an assignment statement is used

- Up to 255 characters can be assigned to a string. If characters are assigned exceeding the valid range, a conversion error occurs.
- Timer type and counter type contacts and coils cannot be used at the left side of an assignment statement.
- Instances of function blocks cannot be used at the left side of an assignment statement. Use the input variable, output variable, or external variable of an instance.

### ■When the result of an arithmetic operation is assigned

When assigning the result of an arithmetic operation to a data type variable with larger data size, convert the variable of the arithmetic operational expression to the data type of the left side in advance.

#### Ex.

To assign the arithmetic operation result with a data size of 16 bits (INT type) to the 32-bit data type (DINT type):

```
varDint1 := varInt1 * 10; //The varInt1 is an INT type variable, and the varDint1 is a DINT type variable.
```

The result of the arithmetic operation will be the same data type as the input operand. For this reason, if the operation result of `varInt1*10` in the above program exceeds the INT type range (-32768 to 32767), the operation result of overflow or underflow is assigned to `varDint1`.

In this case, convert the operand of the operational expression to the data type of the left side in advance.

```
varDint2 := INT_TO_DINT( varInt1 ); //An INT type variable is converted to a DINT type variable.
```

```
varDint1 := varDint2 * 10; //Multiplication is performed in DINT type, and the operation result is assigned.
```

### ■When a sign inversion operator is used in the arithmetic operational expression

If a sign inversion operator is used for the minimum value of each data type, the value remains unchanged.

For example, the minimum value of INT type data will be  $-(-32768) = -32768$ .

If a sign inversion operator is used for variables targeted for automatic conversion of data type, an intended operation result may not be obtained.

**Ex.**

When the value of varInt1 (INT type) is -32768 and the value of varDint1 (DINT type) is 0

```
varDint2 := -varInt1 + varDint1;
```

In this program, the value of (-varInt1) remains unchanged. Therefore, the value, -32768, is assigned to varDint2.

To use a sign inversion operator in an arithmetic operational expression, automatically convert data type before the arithmetic operation or do not use a sign inverted operator in the program.

**Ex.**

When data type is automatically converted before the arithmetic operation

```
varDint3 := varInt;
```

```
varDint2 := -varDint3 + varDint1;
```

**Ex.**

When a sign inversion operator is not used

```
varDint2 := varDint1 - varInt1
```

### ■When the data type is converted from single-precision real number to double-precision real number

When the type conversion function, REAL\_TO\_LREAL, is executed, an error may occur in the conversion result.

Consequently, when the data type is automatically converted or when a function with a return value of real number type (such as SIN function) is used as the right side of an assignment statement or an operand of arithmetic operational expression, an intended operation result may not be obtained.

**Ex.**

An error occurs.

```
varReal1 := -1234.567;
```

```
varLReal1 := ABS(varReal1);
```

In the above program, the data type of the return value of ABS(varReal1) is single-precision real number. Since the return value is converted to a double-precision real number and assigned to varReal1, an error occurs.

Create a program using a function with the data type same as the assignment target.

**Ex.**

No error occurs.

```
varLReal2 := -1234.567;
```

```
varLReal1 := ABS(varLReal2);
```

## ■When a bit type label is used

Once the boolean expression (conditional formula) is established in a select or iteration statement and if a bit type label is set to on in <statement>, the state of the label will be always on.

**Ex.**

Program that keeps the label status on

| ST program                                            | Ladder program performing the processing equivalent to ST program                  |
|-------------------------------------------------------|------------------------------------------------------------------------------------|
| <pre>IF bLabel1 THEN   bLabel2 := TRUE; END_IF;</pre> |  |

To prevent the label from being always on, add a program that turns off the bit type label as shown below.

**Ex.**

Program that avoids the label from being always on

| ST program <sup>*1</sup>                                                       | Ladder program performing the processing equivalent to ST program                  |
|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <pre>IF bLabel1 THEN   bLabel2 := TRUE; ELSE   bLabel2 := FALSE; END_IF;</pre> |  |

<sup>\*1</sup> The above program can also be described as follows.

bLabel2:=bLabel1;

or

OUT(bLabel1,bLabel2);

Note however that if the OUT instruction is used in the <statement>, the program will be in the same state as a program that keeps the label status on.

## ■When a timer function block or counter function block is used

In a select statement, a boolean expression (conditional formula) differs from the execution conditions of timer function blocks or counter function blocks.

**Ex.**

Timer function block

Program example before change

```
IF bLabel1 THEN
  TIMER_100_FB_M_1 (Coil := bLabel2, Preset := wLabel3, ValueIn := wLabel4, ValueOut => wLabel5, Status => bLabel6);
END_IF;
(*When bLabel1 is on and bLabel2 is also on, counting starts.*)
(*When bLabel1 is on and bLabel2 is off, the counted value is cleared.*)
(*When bLabel1 is off and bLabel2 is on, counting stops. The counted value is not cleared.*)
(*When bLabel1 is off and bLabel2 is also off, counting stops. The counted value is not cleared.*)
```

Program example after change

```
TIMER_100_FB_M_1 (Coil := (bLabel1 & bLabel2), Preset := wLabel3, ValueIn := wLabel4, ValueOut => wLabel5, Status => bLabel6);
```

**Ex.**

Counter function block

Program example before change

```
IF bLabel1 THEN
  COUNTER_FB_M_1 (Coil := bLabel2, Preset := wLabel3, ValueIn := wLabel4, ValueOut => wLabel5, Status => bLabel6);
END_IF;
(*When bLabel1 is on and bLabel2 is on/off, the value is incremented by one.*)
(*When bLabel1 is off and bLabel2 is on/off, the value is not counted.*)
(*The counting operation does not depend on the on/off status of bLabel1.*)
```

Program example after change

```
COUNTER_FB_M_1 (Coil := (bLabel1 & bLabel2), Preset := wLabel3, ValueIn := wLabel4, ValueOut => wLabel5, Status => bLabel6);
```

The above examples of programs before change cause problems because the statement related to the timer or counter is not executed unless the select statement is established.

To operate the timer or counter on the basis of the bLabel1 condition and bLabel1 AND condition, do not use control statements but use only function blocks.

The timer and counter can be operated by using the programs after change.

## ■When a FOR...DO statement is used

- A structure member or array element cannot be used for the iteration variable.
- Match the type used in the iteration variable with the types of <final value expression> and <increase expression>.
- <Increase expression> can be omitted. If omitted, <increase expression> is assumed to be 1.
- If 0 is assigned to <increase expression>, the portions after the FOR statement may no longer be executed or an infinite loop may occur.
- In the FOR...DO statement, the iteration variable count processing is performed after execution of <statement--> in the FOR statement. If the count processing is executed in such a way that it exceeds the maximum value of the iteration variable data type or is below the minimum value, an infinite loop occurs.

## ■When instructions executed at the rising edge or falling edge are used

- If the execution condition of the IF or CASE statement has become FALSE or CASE mismatch, the execution result of the rising edge or falling edge in the IF or CASE statement during the previous scan will not be initialized and will be carried over to the next execution.
- After an iteration statement (FOR, WHILE, or REPEAT statement) ends, the execution result of the rising edge or falling edge in the iteration statement during the previous scan will not be initialized and will be carried over to the next execution.
- The following table lists the operations of when instructions executed at the rising edge or falling edge used in the IF or CASE statement.

| Condition                                   |                                      |                                                                 | Operation result                               |                                |                                 |
|---------------------------------------------|--------------------------------------|-----------------------------------------------------------------|------------------------------------------------|--------------------------------|---------------------------------|
| Conditional formula of IF or CASE statement | Instruction execution condition (EN) | On/off determination result of the instruction in the last scan | On/off determination result of the instruction | Instruction at the rising edge | Instruction at the falling edge |
| TRUE or CASE match                          | TRUE                                 | On                                                              | On                                             | Not executed                   | Not executed                    |
|                                             |                                      | Off                                                             | On                                             | Executed                       | Not executed                    |
|                                             | FALSE                                | On                                                              | Off                                            | Not executed                   | Executed                        |
|                                             |                                      | Off                                                             | Off                                            | Not executed                   | Not executed                    |
| FALSE or CASE mismatch                      | TRUE                                 | On                                                              | Off                                            | Not executed                   | Not executed <sup>*1</sup>      |
|                                             |                                      | Off                                                             | Off                                            | Not executed                   | Not executed                    |
|                                             | FALSE                                | On                                                              | Off                                            | Not executed                   | Not executed <sup>*1</sup>      |
|                                             |                                      | Off                                                             | Off                                            | Not executed                   | Not executed                    |

\*1 On the falling edge (on to off), the instruction is not executed because the condition of the IF or CASE statement is not satisfied.

### Ex.

When the PLS instruction (execution condition: rising edge) is used in the IF statement

```
IF bLabel0 THEN
    PLS(bLabel1, bLabel10);
END_IF;
```

- (1) When bLabel0 is off (the conditional formula of the IF statement is FALSE), the on/off determination result will be off. The PLS instruction is not executed. (The bLabel10 remains off.)
- (2) When bLabel0 is on (the conditional formula of the IF statement is TRUE) and bLabel1 is off (the instruction execution condition is off), the on/off determination result will be off. The PLS instruction is not executed. (The bLabel10 remains off.)
- (3) When bLabel0 is on (the conditional formula of the IF statement is TRUE) and bLabel1 is also on (the instruction execution condition is on), the on/off determination result will be off to on (rising edge). The PLS instruction is executed. (The bLabel10 is on for one scan.)

- To execute instructions at the rising edge or falling edge in an iteration statement (FOR, WHILE, or REPEAT statement), use the edge relay (V) or perform index modification. In this case, one point of the edge relay (V) is used for each instruction that uses the edge relay (V) in the system. For this reason, secure the edge relay (V) for the number of instructions used in addition to the number of points used in the iteration statement.

**Ex.**

When instructions executed at the rising edge or falling edge are used in the FOR statement

Example of using the edge relay (V) in one location

(The edge relay (V) is used up to a total of 11 points (V0 to V10 for the INC instruction).)

```
FOR Z0 := 0 TO 9 BY 1 DO
  INC(EGP(M100Z0 , V0Z0) , D100Z0);
END_FOR;
```

Example of using the edge relay (V) in two locations

(The edge relay (V) is used up to a total of 22 points (V0 to V10 for the INC instruction, V11 to V21 for the DEC instruction).)

```
FOR Z0 := 0 TO 9 BY 1 DO
  INC(EGP(M100Z0 , V0Z0) , D100Z0);
  DEC(EGF(M200Z0 , V11Z0) , D200Z0);
END_FOR;
```

### ■When the master control instruction is used

Operations when the master control is off will be as follows.

- A statement in the select statement (IF or CASE statement) or iteration statement (FOR, WHILE, or REPEAT statement) performs no processing.
- For a statement outside the select statement or iteration statement, no processing is performed if it is an assignment statement, and a statement itself is not executed if it is other than assignment statement.

**Ex.**

Statement in the select statement (IF statement)

```
MC(M0 , N1 , M1); //Master control is off.
```

```
IF M2 THEN
```

```
  M3 := M4; // M3 retains the value in the last scan because no processing is performed when the master control is off.
```

```
END_IF;
```

```
M20 := MCR(M0, N1);
```

**Ex.**

Statement (bit assignment statement) outside the select statement or iteration statement

```
MC(M0 , N1 , M1); //Master control is off.
```

```
M3 := M4; //M3 retains the value in the last scan because no processing is performed when the master control is off.
```

```
M20 := MCR(M0, N1);
```

**Ex.**

Statement (OUT instruction) outside the select statement or iteration statement

```
MC(M0 , N1 , M1); //Master control is off.
```

```
OUT(M2, M3); //M3 turns off because the instruction is not executed when the master control is off.
```

```
M20 := MCR(M0, N1);
```

# Constants

## Notation of constants

In the ST program, the following notation of constant is available in addition to the standard notation.

| Applicable data type                        | Type                               | Notation <sup>*1</sup>                                                    | Example                                              |
|---------------------------------------------|------------------------------------|---------------------------------------------------------------------------|------------------------------------------------------|
| Bit                                         | Boolean                            | Add "BOOL#" before the boolean value to be used.                          | BOOL#1, BOOL#0<br>BOOL#TRUE, BOOL#FALSE              |
| Word [unsigned]/bit string [16 bits]        | Binary                             | Add "UINT#2#" or "WORD#2#" before a binary number. <sup>*2</sup>          | UINT#2#10101010<br>WORD#2#10101010                   |
|                                             | Octal                              | Add "UINT#8#" or "WORD#8#" before an octal number. <sup>*2</sup>          | UINT#8#3370<br>WORD#8#3370                           |
|                                             | Decimal                            | Add "UINT#" or "WORD#" before a decimal number. <sup>*2</sup>             | UINT#123<br>WORD#123                                 |
|                                             | Hexadecimal                        | Add "UINT#16#" or "WORD#16#" before a hexadecimal number. <sup>*2</sup>   | UINT#16#FF<br>WORD#16#FF                             |
| Double word [unsigned]/bit string [32 bits] | Binary                             | Add "UDINT#2#" or "DWORD#2#" before a binary number. <sup>*2</sup>        | UDINT#2#1100110011001100<br>DWORD#2#1100110011001100 |

|                                             | Decimal                            | Add "UDINT#" or "DWORD#" before a decimal number. <sup>*2</sup>           | UDINT#456789<br>DWORD#456789                         |
|                                             | Hexadecimal                        | Add "UDINT#16#" or "DWORD#16#" before a hexadecimal number. <sup>*2</sup> | UDINT#16#FFFF<br>DWORD#16#FFFF                       |
| Word [signed]                               | Binary                             | Add "INT#2#" before a binary number.                                      | INT#2#01010101                                       |
|                                             | Octal                              | Add "INT#8#" before an octal number.                                      | INT#8#3370                                           |
|                                             | Decimal                            | Add "INT#" before a decimal number.                                       | INT#-123                                             |
|                                             | Hexadecimal                        | Add "INT#16#" before a hexadecimal number.                                | INT#16#1F                                            |
| Double word [signed]                        | Binary                             | Add "DINT#2#" before a binary number.                                     | DINT#2#0011001100110011                              |
|                                             | Octal                              | Add "DINT#8#" before an octal number.                                     | DINT#8#33703370                                      |
|                                             | Decimal                            | Add "DINT#" before a decimal number.                                      | DINT#-456789                                         |
|                                             | Hexadecimal                        | Add "DINT#16#" before a hexadecimal number.                               | DINT#16#1F1F                                         |
| Single-precision real number                | Real number                        | Add "REAL#" before a real number.                                         | REAL#2.34                                            |
|                                             | Real number (exponential notation) |                                                                           | REAL#1.0E6                                           |
| Double-precision real number                | Real number                        | Add "LREAL#" before a real number.                                        | LREAL#-2.34                                          |
|                                             | Real number (exponential notation) |                                                                           | LREAL#1.001E16                                       |
| String                                      | STRING                             | Enclose a string (ASCII, Shift JIS) in single quotation marks (').        | 'ABC'                                                |
| String [Unicode]                            | WSTRING                            | Enclose a Unicode string in double quotation marks (").                   | "ABC"                                                |

\*1 Notation of constants are not case-sensitive. Notation of constants with K, H, or E cannot be used simultaneously.

\*2 ANY\_NUM of operand for arithmetic operator, ANY\_NUM of arguments for a function call statement, function block call statement, and function call expression, use the notation of constants with "UINT#" or "UDINT#". For the notation of constants with "WORD#" or "DWORD#", an error occurs during the conversion because the data type is recognized as a bit string.

For the notations of constants other than the above, refer to the following.

 User's manual for the controller used

### Point

In the notation of binary, octal, decimal, hexadecimal, and real numbers, the numbers can be separated using an underscore "\_" to make programs easy to see. The binary number notation of double word [unsigned] can be described as follows.

UDINT#2#1100\_1100\_1100\_1100

The numerical value separation using an underscore "\_" is ignored in program processing.

# Labels and devices

## Specification method

Labels and devices can be directly described on ST programs. Labels and devices can be used for the left or right side of an expression or as an argument or return value of a standard function/function block.

For details on labels and devices, refer to the following.

 User's manual for the controller used

### ■ Notation of devices with a type specifier

A word device can be used as any data type by adding a device type specifier to its name.

| Device specifier | Data type                                                                                                                                                                                                                                                    | Example | Description of example                                                 |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|------------------------------------------------------------------------|
| None             | Generic data type ANY16.<br>Word [signed], when only devices are used in such as an arithmetic operational expression.<br>However, when it is specified as a device without a type specifier in a FUN/FB argument, it becomes an argument-defined data type. | D0      | D0 without a type specifier                                            |
| :U               | Word [unsigned]/bit string [16 bits]                                                                                                                                                                                                                         | D0:U    | D0 specified as the word [unsigned]/bit string [16 bits]               |
| :D               | Double word [signed]                                                                                                                                                                                                                                         | D0:D    | D0 and D1 specified as the double word [signed]                        |
| :UD              | Double word [unsigned]/bit string [32 bits]                                                                                                                                                                                                                  | D0:UD   | D0 and D1 specified as the double word [unsigned]/bit string [32 bits] |
| :E               | Single-precision real number                                                                                                                                                                                                                                 | D0:E    | D0 and D1 specified as the single-precision real number                |
| :ED              | Double-precision real number                                                                                                                                                                                                                                 | D0:ED   | D0, D1, D2, and D3 specified as the double-precision real number       |

The following devices can use a device type specifier.

- Data register (D)
- Link register (W)
- Link direct device (J□\W□)
- Module access device (U□\G□)
- CPU buffer memory access device (U3E□\G□)
- File register (R/ZR)
- Refresh data register (RD)

A device type specifier cannot be added to a digit-specified or indirect specified device.

### ■ Device specification method

Devices can be specified in the following methods.

- Index modification
- Indirect specification
- Bit specification ( Page 33 Bit data)
- Digit specification ( Page 34 16-bit data (word data),  Page 36 32-bit data (double word data))

For details on index modification and indirect specification, refer to the following.

 User's manual for the controller used

## Precautions

- The pointer type cannot be used in ST programs.
- When the timer, counter, or retentive timer device is used as current value, the data type will be the word [unsigned]/bit string [16 bits]. When the long timer, long counter, or long retentive timer device is used as current value, the data type will be the double word [unsigned]/bit string [32 bits].
- When performing assignment using digit specification, match the data type between the left and right sides.

**Ex.**

```
D0:=K5X40;
```

In this example, a program error occurs because K5X40 is the double word type and D0 is the word type.

- If the right side is greater than the left side when performing assignment using digit specification, data is transferred to within the range of the number of applicable points of the left side.

**Ex.**

```
K5X40:=2#1011_1101_1111_0111_0011_0001;
```

In this example, K5X40 has 20 applicable points and therefore 1101\_1111\_0111\_0011\_0001 (20 digits) is assigned to K5X40.

- When using the current value (such as T<sub>N</sub>) of the counter (C), timer (T), or retentive timer (ST) as a type other than the word [unsigned]/bit string [16 bits], or when using the current value (such as LT<sub>N</sub>) of the long counter (LC), long timer (LT), or long retentive timer (LST) as a type other than the double word [unsigned]/bit string [32 bits], use the type conversion functions.

**Ex.**

```
varInt:=WORD_TO_INT(T0);(*A type conversion function is used.*)
```

### ■When performing automatic conversion of data type with devices

Add a device type specifier when using a word device in a data type other than word [signed]. (  Page 107 Notation of devices with a type specifier)

**Ex.**

When transferring the values of D2 and D3 to dwordLabel1, a double word [unsigned] label

```
//Example of when adding a device type specifier and transferring the values in a correct data type
```

```
dwordLabel1 := D2:UD;
```

```
//Since the data type of D2: UD (D2 with a device type specifier) is double word [unsigned], the values of D2 and D3 are transferred to dwordLabel1.
```

```
//Example of an unintended transfer result
```

```
dwordLabel1 := D2;
```

```
//Since the data type of D2 without a device type specifier is word [signed], the data type is automatically converted into double word [unsigned] and data is transferred to dwordLabel1.
```

```
//Therefore, the value of D3 is not transferred but only the value of D2 is transferred.
```

## Comments

The following table lists the comments that can be used in ST programs.

| Type                  | Symbol | Description                                                                                                                          | Example                                                                                                                                                       |
|-----------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Single-line comment   | //     | The portion from the start symbol "//" to the end of the line is regarded as a comment.                                              | //comment                                                                                                                                                     |
| Multiple-line comment | (**)   | The portion from the start symbol "(" to the end symbol ")" is regarded as a comment.<br>A line feed can be inserted in a comment.   | <div> <div>■</div>No line feed<br/>(*comment*)           </div> <div> <div>■</div>With a line feed<br/>(*line-1 comment<br/>line-2 comment*)           </div> |
|                       | /**/   | The portion from the start symbol "/*" to the end symbol "*/" is regarded as a comment.<br>A line feed can be inserted in a comment. | <div> <div>■</div>No line feed<br/>/*comment*/           </div> <div> <div>■</div>With a line feed<br/>/*line-1 comment<br/>line-2 comment*/           </div> |

Do not write a comment containing an end symbol in a multiple-line comment.

# 5 FBD/LD

FBD/LD (function block diagram/ladder diagram) is a graphic language which describes programs by connecting blocks that perform predefined processing, variable elements, and constant elements along the flow of data and signals.

## Point

- This chapter describes the operation and specifications of the FBD/LD. For the operation method of the engineering tool for creating an FBD/LD program, refer to the following.

📖 GX Works3 Operating Manual

## 5.1 Configuration

The following are the programs written in FBD/LD.

- (1) Worksheet
- (2) LD element
- (3) FBD element
- (4) Common element
- (5) Connection point
- (6) Connection line

In FBD/LD programs, data flows from the output point of a function block, function, variable (label or device), or constant to the input point of another function block or variable.

# Program elements

## FBD elements

The following table lists FBD elements consisting an FBD/LD program.

| Item                |                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Variable            |  | Stores a value. A specific data type is assigned to each variable, and only data of the assigned data type are stored.<br>Labels and devices can be specified as a variable.                                                                                                                                                                                                             |
| Constant            |  | Outputs a specified value.                                                                                                                                                                                                                                                                                                                                                               |
| Function (FUN)      |  | Executes a function. <ul style="list-style-type: none"> <li>How to create functions (📖 GX Works3 Operating Manual)</li> <li>Standard function (👉 Page 183 Standard Functions)</li> </ul>                                                                                                                                                                                                 |
| Function block (FB) |  | Executes a function block. <ul style="list-style-type: none"> <li>How to create function blocks (📖 GX Works3 Operating Manual)</li> <li>Standard function block (👉 Page 194 Standard Function Blocks)</li> <li>Motion control function block (👉 Page 196 MOTION CONTROL FUNCTION BLOCK LIST)</li> <li>Module function blocks (📖 Function Block Reference for the module used)</li> </ul> |

### ■Data type of constant elements

The data type of the value input to a constant is not determined when the value is input. It is determined when the constant element is connected to another FBD element with a connection line. The data type will be the same as that of the connected FBD element.

#### Ex.

When the constant value is 1

The possible data types are BOOL, WORD, DWORD, INT, DINT, REAL, and LREAL, but the data type of the input value cannot be determined at this point. The data type is determined when the constant is connected to another FBD element.

- (1) The data type has not been determined.
- (2) INT data type
- (3) INT data type

### ■Automatic conversion of data type

If the data types differ between connected elements, one data type may be converted automatically.

To prevent data from being lost during type conversion, conversion is performed only from a smaller size data type to a larger size data type. The data type automatic conversion processing in FBD/LD is same as that in ST language. For details, refer to the following.

👉 Page 97 Automatic conversion of data type

■Input/output points of a function

- Connect all input points of a function with another element.
- The data type is assigned to each input variable and output variable of a function. Match the data type of an element connected to the input point or output point with that of the input variable or output variable.

■Precautions for connecting the output variables of the function with EN and function block with EN to another element

When ENO of the function with EN and function block with EN are FALSE (not executed), the program operation differs depending on the element connected.

| Element connected                                           | Program operation when ENO of the function with EN and function block with EN are FALSE (not executed)                                                                         |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <div><div>• Function</div><div>• Function block</div></div> | The values of the input variables connected to the output variables of the function with EN and function block with EN are undefined.                                          |
| Coil                                                        | The values of the coils connected to the output variables of the function with EN and function block with EN are FALSE. When inverse coils are connected, the values are TRUE. |
| Other than above                                            | The values of the elements connected to the output variables of the function with EN and function block with EN are not changed. (The last values are input.)                  |

Unintended operation may occur if the output variable of the function block with EN is directly connected to the input variable of other functions or function blocks.

To prevent an undefined value from being used, refer to either of the following examples for the connection.

Ex.

Connect elements so that the function with EN or function block with EN is the connection destination. Connect ENO (connection source) to EN (connection destination) as well.

Ex.

Connect elements using the SEL (selection function) so that the last value is input if ENO is FALSE.

## LD elements

The following table lists the LD elements that can be used in FBD/LD programs.

| Item                       |                                                                                   | Description                                                                                                                                                        |
|----------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Left rail                  |  | An element that indicates a rail.<br>A start point of ladder program.<br>The output of the left rail is always on.                                                 |
| Normally open contact      |  | Energized when the specified device or label is on.                                                                                                                |
| Normally closed contact    |  | Energized when the specified device or label is off.                                                                                                               |
| Rising edge pulse          |  | Energized on the rising edge (off to on) of the specified device or label.                                                                                         |
| Falling edge pulse         |  | Energized on the falling edge (on to off) of the specified device or label.                                                                                        |
| Negated rising edge pulse  |  | Energized when the specified device or label is off, on, or on the falling edge (on to off).                                                                       |
| Negated falling edge pulse |  | Energized when the specified device or label is off, on, or on the rising edge (off to on).                                                                        |
| Coil                       |  | Outputs the operation result to the specified device or label.                                                                                                     |
| Inverse coil               |  | When the operation result turns off, the specified device or label turns on.                                                                                       |
| Set coil                   |  | When the operation result turns on, the specified device or label turns on.<br>The device or label keeps on state even after the operation result turns off.       |
| Reset coil                 |  | When the operation result turns on, the specified device or label turns off.<br>If the operation result is off, the status of the device or label does not change. |

### ■AND operation and OR operation of contact elements

At each contact, an AND operation or OR operation is performed depending on the connection status, and the operation result is output.

- Series connection (1): An AND operation is performed with the previous operation result.
- Parallel connection (2): An OR operation is performed with the previous operation result.

- (1) Contact connected in series  
(2) Contact connected in parallel

■When another program element is connected to a connection point of coil for output

When another program element is connected to a connection point of coil for output in series, the operation is the same as that of the parallel connection.

| Item                           | Description                                                                        |
|--------------------------------|------------------------------------------------------------------------------------|
| Program example                |  |
| Operation at the above example |  |

## Common elements

The following table lists the common elements that can be used in FBD/LD programs.

| Item       |                                                                                   | Description                                                                                                                                                                                                                                                                                                                              |
|------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Jump       |  | Jumps the execution processing to a jump element. Processing between this element and a jump label is not performed.<br>Whether to perform jump processing or not is controlled by inputting on/off information to the element.<br>On: Jump processing performed<br>Off: Jump processing not performed                                   |
| Jump label |  | A jump destination of a jump element in the same program. When the jump processing is performed, the program continues from the processing located after the jump label.                                                                                                                                                                 |
| Connector  |  | Used as a substitute for a connection line.<br>Processing moves to a connector element used as a pair.<br>One or more input connectors can be used as a pair of one output connector.                                                                                                                                                    |
| Return     |  | Stops the execution processing after this element. Use the element not to execute the program, functions, and function blocks after the element.<br>Whether to perform return processing or not is controlled by inputting on/off information to the element.<br>On: Return processing performed<br>Off: Return processing not performed |
| Comment    |  | Used to write a comment.                                                                                                                                                                                                                                                                                                                 |
| Inline ST  |  | Displays an ST program in the FBD/LD editor.<br>Double-clicking an inserted inline ST element displays the ST editor for editing or monitoring an ST program.<br>For details, refer to the following.<br> Page 120 Inline ST                            |

### ■ Jump element

- If the timer whose coil is on is jumped, the time cannot be measured correctly.
- A jump label can be located before the jump element in the program sequence. If located, create a program so that the watchdog timer setting value is not exceeded. (How to exit from a loop must be considered.)
- Specify a pointer type local label for a jump element and a jump label. The structure members cannot be used.
- The CJ, SCJ, and JMP instructions (for pointer branch) cannot be used. Use a jump element when jump processing is required.
- Processing cannot be jumped to/from the outside of the program block.

| Jump related operation                                      | Availability  |
|-------------------------------------------------------------|---------------|
| Jumping to the outside of the program block <sup>*1</sup>   | Not supported |
| Jumping from the outside of the program block <sup>*1</sup> | Not supported |
| Calling a subroutine program                                | Supported     |
| Being called as a subroutine program                        | Not supported |

<sup>\*1</sup> Branching by using the BREAK instruction is included.

## ■Return element

The operation of a return element differs depending on the POU (program, function, or function block) used.

| POU used       | Description                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Program        | Execution of the program is stopped.                                                                                                   |
| Function       | Execution of the function is stopped, and processing returns to the step next to the instruction that called the function.             |
| Function block | Execution of the function block is stopped, and processing returns to the step next to the instruction that called the function block. |

## ■Connector element

A connector element is used to place the program within the area to be displayed in the FBD/LD editor or to be printed.

## Connection line

A connection line is a line that connects the end points of FBD element, LD element, and common element. When connected, the value is passed from the left end to the right end of the line. The data types of the program elements connected must be identical, or support automatic data type conversion.

## Connection point

A connection point is an end point of FBD element, LD element, and common element for connecting them to create an FBD/LD program.

The left-side end point is for input, and the right-side end point is for output.

| Item           | Connection point for input                                                          | Connection point for output                                                                                                               |
|----------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Contact        |    |                                                         |
| Coil           |    |                                                         |
| Variable       |    |                                                         |
| Constant       | —                                                                                   |                                                         |
| Function       |   | <br>The return value of the function is not displayed. |
| Function block |  |                                                       |

When connected, the connection point is hidden.

## I/O point inversion

The input value to a program element or the output value from a program element can be inverted at the connection point. The connection point where the value is inverted (FALSE to TRUE or TRUE to FALSE) is displayed with a black circle.

The value of the following data types can be inverted: BOOL, WORD, DWORD, ANY\_BIT, and ANY\_BOOL.

# Constant

## Notation of constants

The following table lists the notations of strings in FBD/LD programs.

| Data type        |         | Notation                                                           | Example                                                                             |
|------------------|---------|--------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| String           | STRING  | Enclose a string (ASCII, Shift JIS) in single quotation marks ('). |  |
| String [Unicode] | WSTRING | Enclose a Unicode string in double quotation marks (").            |  |

For the notations of constants other than the above, refer to the following.

 User's manual for the controller used

## Labels and devices

### Specification method

Labels and devices can be directly described on FBD/LD programs. Labels and devices can be used as an input point or output point of a program element and an argument or return value of a standard function/function block.

For details on labels and devices, refer to the following.

 User's manual for the controller used

#### ■ Notation of devices with a type specifier

A word device can be used as any data type by adding a device type specifier to its name.

The device type specifiers and applicable devices are the same as those for ST programs. For details, refer to the following.

 Page 107 Notation of devices with a type specifier

If the data type of a word device is not specified, it will be determined by the device type.

| Word device                                                                                                                      | Data type |
|----------------------------------------------------------------------------------------------------------------------------------|-----------|
| Current value of the timer (TN), current value of the retentive timer (STN), current value of the counter (CN)                   | WORD      |
| Current value of the long timer (LTN), current value of the long retentive timer (LSTN), current value of the long counter (LCN) | DWORD     |
| Long index register (LZ)                                                                                                         | DINT      |
| Other than above                                                                                                                 | ANY16     |

Precautions

■When labels are used

Local devices cannot be used as an array index. To use local devices as an array index, assign the target device to another device, and specify the assigned device.

■When performing automatic conversion of data type with devices

Add a device type specifier when using a word device in a data type other than word [signed]. (  Page 118 Notation of devices with a type specifier)

Ex.

When the values of D2 and D3 are transferred to dwordLabel1, a double word [unsigned] label

| Example of when adding a device type specifier and transferring the values in a correct data type                                                                                                                                                     | Example of an unintended transfer result                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <div></div> <p>Since the data type of D2:UD (D2 with a device type specifier) is double word [unsigned], the values of D2 and D3 are transferred to dwordLabel1.</p> | <div></div> <p>Since the data type of D2 without a device type specifier is word [signed], the data type is automatically converted into double word [unsigned] and data is transferred to dwordLabel1.<br/>Therefore, the value of D3 is not transferred but only the value of D2 is transferred.</p> |

## 5.2 Inline ST

The inline ST is the function used to create an inline ST element that displays an ST program in the FBD/LD editor, and edit and monitor it.

This function enables to create complex numerical operations and string processing easily in FBD/LD programs.

- Program that does not use the inline ST

- Program that uses the inline ST

### Specifications

Double-clicking an inserted inline ST element displays the ST editor for editing or monitoring an ST program.

For the specifications of the ST program described to the inline ST, refer to the specifications of the ST language.

☞ Page 92 STRUCTURED TEXT LANGUAGE

### Precautions

- Up to 64 inline ST elements can be inserted into a single POU of an FBD/LD program.
- Using a RETURN statement in the inline ST causes the processing in the inline ST element to end, instead of the processing of the program block.
- Since inline ST elements have no connection points, an inline ST element inserted into an FBD/LD program is executed every scan.

## 5.3 Program Execution Order

### Execution order of program elements

The execution order of program elements in the FBD/LD editor is determined by the location and connecting status.

(1) Program elements are executed from left to right.

(2) Program elements are executed from top to bottom.

The execution order is displayed under each program element. After the program is converted, the determined execution order is displayed.

## Precautions

For a program that uses functions, do not directly connect the return value of a function and an input variable of another function, but connect a variable element between them.

**Ex.**

When the variable element (1) is connected between the return value and input variable

Connecting the return value of a function and the input variable of another function directly may lead an execution order to an unintended one.

**Ex.**

An unintended execution order

Since both the output variable (3) that comes from another program element and the return value (2) of the program element arranged on the left are connected as inputs of the program element arranged on the right, the execution order has changed.

## PART 2

# LISTS OF INSTRUCTIONS AND FUN/FB

This part consists of the following chapters.

6 INSTRUCTION LIST

---

7 NETWORK INSTRUCTION LIST

---

8 STANDARD FUNCTION/STANDARD FUNCTION BLOCK LISTS

---

9 MOTION CONTROL FUNCTION BLOCK LIST

---

10 NETWORK FUNCTION BLOCK LIST

---

# 6

## INSTRUCTION LIST

The following table summarizes how to read the instruction lists.

| Item               | Description                                     |
|--------------------|-------------------------------------------------|
| Instruction symbol | An instruction name                             |
| Processing details | An overview of the instruction                  |
| Reference          | Section where detailed information is described |

## 6.1 Sequence Instructions

### Contact instructions

#### ■ Operation start, series connection, parallel connection

| Instruction symbol | Processing details                                                                                                                                                                                                   | Reference                           |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| LD                 | Outputs the on/off information of the specified device as the operation result. (Normally open contact operation start instruction)                                                                                  | Page 206 LD, LDI, AND, ANI, OR, ORI |
| LDI                | Outputs the on/off information of the specified device as the operation result. (Normally closed contact operation start instruction)                                                                                |                                     |
| AND                | Performs an AND operation between the on/off information of the specified device and the previous operation result, and output the operation result. (Normally open contact series connection instruction)           |                                     |
| ANI                | Performs an AND operation between the on/off information of the specified device and the previous operation result, and output the operation result. (Normally closed contact series connection instruction)         |                                     |
| OR                 | Performs an OR operation between the on/off information of the specified device and the previous operation result, and output the operation result. (Single normally open contact parallel connection instruction)   |                                     |
| ORI                | Performs an OR operation between the on/off information of the specified device and the previous operation result, and output the operation result. (Single normally closed contact parallel connection instruction) |                                     |

#### ■ Pulse operation start, pulse series connection, pulse parallel connection

| Instruction symbol | Processing details                                                                                                          | Reference                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| LDP                | Turns on only at the rising edge (off to on) of the specified bit device. (Rising edge pulse operation start instruction)   | Page 208 LDP, LDF, ANDP, ANDF, ORP, ORF |
| LDF                | Turns on only at the falling edge (on to off) of the specified bit device. (Falling edge pulse operation start instruction) |                                         |
| ANDP               | Performs an AND operation with the previous operation result. (Rising edge pulse series connection instruction)             |                                         |
| ANDF               | Performs an AND operation with the previous operation result. (Falling edge pulse series connection instruction)            |                                         |
| ORP                | Performs an OR operation with the previous operation result. (Rising edge pulse parallel connection instruction)            |                                         |
| ORF                | Performs an OR operation with the previous operation result. (Falling edge pulse parallel connection instruction)           |                                         |

## ■Pulse NOT operation start, pulse NOT series connection, pulse NOT parallel connection

| Instruction symbol | Processing details                                                                                                                     | Reference                                     |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| LDPI               | Turns on when the specified device is off, on, or at the falling edge (on to off). (Rising edge pulse NOT operation start instruction) | Page 211 LDPI, LDFI, ANDPI, ANDFI, ORPI, ORFI |
| LDFI               | Turns on when the specified device is at the rising edge (off to on), off, or on. (Falling edge pulse NOT operation start instruction) |                                               |
| ANDPI              | Performs an AND operation with the previous operation result. (Rising edge pulse NOT series connection instruction)                    |                                               |
| ANDFI              | Performs an AND operation with the previous operation result. (Falling edge pulse NOT series connection instruction)                   |                                               |
| ORPI               | Performs an OR operation with the previous operation result. (Rising edge pulse NOT parallel connection instruction)                   |                                               |
| ORFI               | Performs an OR operation with the previous operation result. (Falling edge pulse NOT parallel connection instruction)                  |                                               |

## Association instructions

### ■Ladder block series/parallel connection

| Instruction symbol | Processing details                                                                        | Reference         |
|--------------------|-------------------------------------------------------------------------------------------|-------------------|
| ANB                | Performs AND operations between logical blocks (series connection between logical blocks) | Page 214 ANB, ORB |
| ORB                | Performs OR operations between logical blocks (series connection between logical blocks)  |                   |

### ■Inverting the operation result

| Instruction symbol | Processing details                                                  | Reference    |
|--------------------|---------------------------------------------------------------------|--------------|
| INV                | Inverts the operation result up to just before the INV instruction. | Page 215 INV |

### ■Converting the operation result into a pulse

| Instruction symbol | Processing details                                                                          | Reference         |
|--------------------|---------------------------------------------------------------------------------------------|-------------------|
| MEP                | Turns on at the rising edge (off to on) of the operation result up to the MEP instruction.  | Page 216 MEP, MEF |
| MEF                | Turns on at the falling edge (on to off) of the operation result up to the MEF instruction. |                   |

### ■Converting the edge relay operation result into a pulse

| Instruction symbol | Processing details                                                                                                                                             | Reference         |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| EGP                | Stores the operation result up to the EGP instruction in the edge relay (V). The instruction turns on at the rising edge (off to on) of the operation result.  | Page 217 EGP, EGF |
| EGF                | Stores the operation result up to the EGF instruction in the edge relay (V). The instruction turns on at the falling edge (on to off) of the operation result. |                   |

## Output instructions

### ■Out (excluding the timer, counter, and annunciator)

| Instruction symbol | Processing details                                    | Reference    |
|--------------------|-------------------------------------------------------|--------------|
| OUT                | Outputs the operation result to the specified device. | Page 219 OUT |

### ■Timer, long timer

| Instruction symbol | Processing details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Reference                               |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| OUT T              | <p>Starts time measurement when the operation result up to the OUT instruction is on. When time is up, the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).</p> <ul style="list-style-type: none"> <li>• OUT T: Low-speed timer instruction</li> <li>• OUTH T: High-speed timer instruction</li> <li>• OUT ST: Low-speed retentive timer instruction</li> <li>• OUTH ST: High-speed retentive timer instruction</li> <li>• OUT LT: Low-speed long timer instruction</li> <li>• OUT LST: Low-speed long retentive timer instruction</li> </ul> | Page 221 OUT T, OUTH T, OUT ST, OUTH ST |
| OUTH T             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                         |
| OUT ST             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                         |

### ■Counter, long counter

| Instruction symbol | Processing details                                                                                                                                                                                                                                                                                                                                                                                                   | Reference       |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| OUT C              | <p>Increments the current counter value (count value) by one when the operation result up to the OUT instruction turns on. When the count value reaches the set value, the normally open contact of the counter turns on (continuity state) and the normally closed contact turns off (non-continuity state).</p> <ul style="list-style-type: none"> <li>• OUT C: Counter</li> <li>• OUT LC: Long counter</li> </ul> | Page 227 OUT C  |
| OUT LC             |                                                                                                                                                                                                                                                                                                                                                                                                                      | Page 229 OUT LC |

### ■Annunciator

| Instruction symbol | Processing details                                                                     | Reference      |
|--------------------|----------------------------------------------------------------------------------------|----------------|
| OUT F              | Outputs the operation result up to the OUT F instruction to the specified annunciator. | Page 231 OUT F |

### ■Setting devices (excluding annunciator)

| Instruction symbol | Processing details          | Reference    |
|--------------------|-----------------------------|--------------|
| SET                | Turns on the specified bit. | Page 232 SET |

### ■Resetting devices (excluding annunciator)

| Instruction symbol | Processing details                                                                                                                          | Reference    |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| RST                | Turns off the specified device. For the timer and counter, the instruction clears the current value to 0 and turns off the contact or coil. | Page 234 RST |

### ■Setting/resetting annunciator

| Instruction symbol | Processing details                   | Reference      |
|--------------------|--------------------------------------|----------------|
| SET F              | Turns on the specified annunciator.  | Page 236 SET F |
| RST F              | Turns off the specified annunciator. | Page 238 RST F |

### ■Rising/falling edge output

| Instruction symbol | Processing details                                                                                   | Reference    |
|--------------------|------------------------------------------------------------------------------------------------------|--------------|
| PLS                | Turns on the specified device for one scan on the rising edge (off to on) of the execution command.  | Page 240 PLS |
| PLF                | Turns on the specified device for one scan on the falling edge (on to off) of the execution command. | Page 242 PLF |

## ■Inverting the bit device output

| Instruction symbol | Processing details                          | Reference   |
|--------------------|---------------------------------------------|-------------|
| FF                 | Inverts the status of the specified device. | Page 244 FF |

## ■Converting the direct access output into a pulse

| Instruction symbol | Processing details                                                  | Reference         |
|--------------------|---------------------------------------------------------------------|-------------------|
| DELTA              | Converts the specified direct access output (DY) into pulse output. | Page 245 DELTA(P) |
| DELTAP             |                                                                     |                   |

## Shift instructions

### ■Shifting bit devices

| Instruction symbol | Processing details                                                                                                                            | Reference       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| SFT                | Shifts the on/off state of the device area just before the one specified to the specified device area, and turns off the shift source device. | Page 247 SFT(P) |
| SFTP               |                                                                                                                                               |                 |

## Master control instructions

### ■Setting/resetting a master control

| Instruction symbol | Processing details       | Reference        |
|--------------------|--------------------------|------------------|
| MC                 | Starts a master control. | Page 249 MC, MCR |
| MCR                | Ends a master control.   |                  |

## Termination instructions

### ■Ending the main routine program

| Instruction symbol | Processing details                                                                                    | Reference     |
|--------------------|-------------------------------------------------------------------------------------------------------|---------------|
| FEND               | Separates the main routine program from subroutine programs and interrupt programs in a program file. | Page 253 FEND |

### ■Ending the sequence program

| Instruction symbol | Processing details              | Reference    |
|--------------------|---------------------------------|--------------|
| END                | Indicates the end of a program. | Page 254 END |

## Stop instruction

### ■Stopping the sequence program

| Instruction symbol | Processing details                                                                                                                                   | Reference     |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| STOP               | Stops the operation of the controller. (The operation of this instruction is the same as setting the switch of the controller to the STOP position.) | Page 256 STOP |

## No operation instruction

### ■No operation

| Instruction symbol | Processing details                                                                           | Reference      |
|--------------------|----------------------------------------------------------------------------------------------|----------------|
| NOPLF              | This instruction is a no-operation instruction and has no impact on the previous operations. | Page 257 NOPLF |

## 6.2 Basic Instructions

### Comparison operation instructions

#### ■Comparing 16-bit binary data

| Instruction symbol      | Processing details                                                                                   | Reference                           |
|-------------------------|------------------------------------------------------------------------------------------------------|-------------------------------------|
| LD=, AND=, OR=          | Compares the two sets of 16-bit binary data specified. (Devices are used as normally open contacts.) | Page 258 LD□(_U), AND□(_U), OR□(_U) |
| LD=_U, AND=_U, OR=_U    |                                                                                                      |                                     |
| LD<>, AND<>, OR<>       |                                                                                                      |                                     |
| LD<>_U, AND<>_U, OR<>_U |                                                                                                      |                                     |
| LD>, AND>, OR>          |                                                                                                      |                                     |
| LD>_U, AND>_U, OR>_U    |                                                                                                      |                                     |
| LD<=, AND<=, OR<=       |                                                                                                      |                                     |
| LD<=_U, AND<=_U, OR<=_U |                                                                                                      |                                     |
| LD<, AND<, OR<          |                                                                                                      |                                     |

## 6.3 Application Instructions

### Program control

#### Program branch instructions

##### ■Pointer branch

| Instruction symbol | Processing details                                                                                             | Reference             |
|--------------------|----------------------------------------------------------------------------------------------------------------|-----------------------|
| CJ                 | Executes the program specified by the pointer number within the same program file.                             | Page 534 CJ, SCJ, JMP |
| SCJ                | Executes the program specified by the pointer number within the same program file starting with the next scan. |                       |
| JMP                | Unconditionally executes the program specified by the pointer number within the same program file.             |                       |

##### ■Jumping to END

| Instruction symbol | Processing details                                                          | Reference      |
|--------------------|-----------------------------------------------------------------------------|----------------|
| GOEND              | Invokes a jump to the FEND or END instruction within the same program file. | Page 537 GOEND |

#### Program execution control instructions

##### ■Disabling/enabling interrupt programs

| Instruction symbol | Processing details                            | Reference       |
|--------------------|-----------------------------------------------|-----------------|
| DI                 | Disables the execution of interrupt programs. | Page 538 DI, EI |
| EI                 | Clears the interrupt disabled state.          |                 |

##### ■Disabling the interrupt program with specified priority or lower

| Instruction symbol | Processing details                                                                              | Reference   |
|--------------------|-------------------------------------------------------------------------------------------------|-------------|
| DI                 | This instruction disables execution of interrupt programs with the specified priority or lower. | Page 542 DI |

##### ■Interrupt program mask

| Instruction symbol | Processing details                                                                                      | Reference      |
|--------------------|---------------------------------------------------------------------------------------------------------|----------------|
| IMASK              | Enables or disables the execution of the interrupt program with the specified interrupt pointer number. | Page 547 IMASK |

##### ■Disabling/enabling the specified interrupt pointer

| Instruction symbol | Processing details                                                                                      | Reference       |
|--------------------|---------------------------------------------------------------------------------------------------------|-----------------|
| SIMASK             | Enables or disables the execution of the interrupt program with the specified interrupt pointer number. | Page 549 SIMASK |

##### ■Returning from the interrupt program

| Instruction symbol | Processing details                                           | Reference     |
|--------------------|--------------------------------------------------------------|---------------|
| IRET               | Indicates the end of the processing of an interrupt program. | Page 551 IRET |

##### ■Resetting the watchdog timer

| Instruction symbol | Processing details         | Reference       |
|--------------------|----------------------------|-----------------|
| WDT                | Resets the watchdog timer. | Page 552 WDT(P) |
| WDTP               |                            |                 |

## Structure creation instructions

### ■Performing the FOR to NEXT instruction loop

| Instruction symbol | Processing details                                     | Reference          |
|--------------------|--------------------------------------------------------|--------------------|
| FOR                | Executes the processing between FOR to NEXT (n) times. | Page 553 FOR, NEXT |
| NEXT               |                                                        |                    |

### ■Forcibly terminating the FOR to NEXT instruction loop

| Instruction symbol | Processing details                                                                                                                                                           | Reference         |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| BREAK              | These instructions forcibly terminate the loop processing between the FOR and NEXT instructions, and pass the control to the processing of FOR to NEXT instruction or later. | Page 556 BREAK(P) |
| BREAKP             |                                                                                                                                                                              |                   |

### ■Calling a subroutine program

| Instruction symbol | Processing details                                                                                                                                                   | Reference        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| CALL               | Executes a subroutine program specified by (P) when the input condition is met.<br>(For (s1) to (s5), specify the arguments to be passed to the subroutine program.) | Page 558 CALL(P) |
| CALLP              |                                                                                                                                                                      |                  |

### ■Returning from the subroutine program called

| Instruction symbol | Processing details                         | Reference    |
|--------------------|--------------------------------------------|--------------|
| RET                | Indicates the end of a subroutine program. | Page 564 RET |

### ■Calling a subroutine program and turning the output off

| Instruction symbol | Processing details                                                                                                                                                                                       | Reference         |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| FCALL              | Performs non-execution processing of the subroutine program specified by (P) when the input conditions are not met.<br>(For (s1) to (s5), specify the arguments to be passed to the subroutine program.) | Page 565 FCALL(P) |
| FCALLP             |                                                                                                                                                                                                          |                   |

### ■Calling a subroutine program in the specified program file

| Instruction symbol | Processing details                                                                                                                                                                                | Reference         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| ECALL              | Executes the subroutine program specified by (P) of the specified program when the input conditions are met.<br>(For (s1) to (s5), specify the arguments to be passed to the subroutine program.) | Page 571 ECALL(P) |
| ECALLP             |                                                                                                                                                                                                   |                   |

### ■Calling a subroutine program in the specified program file and turning the output off

# Debugging and failure diagnostic

## Debugging and failure diagnostic instructions

### ■Resetting the error display and the annunciator display

| Instruction symbol | Processing details                                                                                                            | Reference      |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|----------------|
| LED R              | This instruction resets the self-diagnostic error (continuation error) display and the annunciator display of the controller. | Page 720 LED R |

## String processing

### String processing instructions

#### ■Comparing string data

| Instruction symbol      | Processing details                                                                                | Reference                     |
|-------------------------|---------------------------------------------------------------------------------------------------|-------------------------------|
| LD\$=, AND\$=, OR\$=    | Compares the string specified by (s1) with the string specified by (s2) (character by character). | Page 722 LD\$□, AND\$□, OR\$□ |
| LD\$<>, AND\$<>, OR\$<> |                                                                                                   |                               |
| LD\$>, AND\$>, OR\$>    |                                                                                                   |                               |
| LD\$<=, AND\$<=, OR\$<= |                                                                                                   |                               |
| LD\$<, AND\$<, OR\$<    |                                                                                                   |                               |
| LD\$>=, AND\$>=, OR\$>= |                                                                                                   |                               |

#### ■Concatenating string data

| Instruction symbol | Processing details                                                                                                                                                     | Reference                                     |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| \$+                | Connects the strings in the device specified by (s) to those in the device specified by (d), and stores the connected data in the device specified by (d) and later.   | Page 725 \$+(P) [when two operands are set]   |
| \$+P               |                                                                                                                                                                        |                                               |
| \$+                | Connects the strings in the device specified by (s2) to those in the device specified by (s1), and stores the connected data in the device specified by (d) and later. | Page 727 \$+(P) [when three operands are set] |
| \$+P               |                                                                                                                                                                        |                                               |

#### ■Transferring string data

| Instruction symbol | Processing details                                                                                     | Reference            |

## Timing check instructions

### ■Generating timing pulses

| Instruction symbol | Processing details                                                                                                                                                                                                                                                                     | Reference      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| DUTY               | <p>Turns on the user timing clock for the specified number of scans and off for the specified number of scans.</p> <p>(d) </p> <p>(n1): (n1) scans<br/> (n2): (n2) scans<br/> (d): SM420 to SM424</p> | Page 1003 DUTY |

### ■Measuring time of the specified data

| Instruction symbol | Processing details                                                                                                                          | Reference        |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| TIMCHK             | Measures the on time of the input condition and, if the on time has continued as specified or longer, turns on the device specified by (d). | Page 1005 TIMCHK |

## Module access

### Module access instructions

#### ■Performing I/O refresh

| Instruction symbol | Processing details                                                     | Reference        |
|--------------------|------------------------------------------------------------------------|------------------|
| RFS                | Performs partial refresh of the relevant input/output during one scan. | Page 1007 RFS(P) |
| RFSP               |                                                                        |                  |

#### ■Reading 1-word/2-word data from another module (16-bit specification)

| Instruction symbol | Processing details                                                                                              | Reference                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------|-----------------------------|
| FROM               | Reads (n) words of data in units of 16 bits from the buffer memory areas of the intelligent function modules.   | Page 1009 FROM(P), DFROM(P) |
| FROMP              |                                                                                                                 |                             |
| DFROM              | Reads (n)×2 words of data in units of 16 bits from the buffer memory areas of the intelligent function modules. |                             |
| DFROMP             |                                                                                                                 |                             |

#### ■Writing 1-word/2-word data to a module (16-bit specification)

| Instruction symbol | Processing details                                                                                            | Reference               |
|--------------------|---------------------------------------------------------------------------------------------------------------|-------------------------|
| TO                 | Writes (n) words of data in units of 16 bits to the buffer memory areas of the intelligent function module.   | Page 1012 TO(P), DTO(P) |
| TOP                |                                                                                                               |                         |
| DTO                | Writes (n)×2 words of data in units of 16 bits to the buffer memory areas of the intelligent function module. |                         |
| DTOP               |                                                                                                               |                         |

#### ■Reading 1-word/2-word data from another module (32-bit specification)

| Instruction symbol | Processing details                                                                                              | Reference                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------|-------------------------------|
| FROMD              | Reads (n) words of data in units of 32 bits from the buffer memory areas of the intelligent function modules.   | Page 1017 FROMD(P), DFROMD(P) |
| FROMDP             |                                                                                                                 |                               |
| DFROMD             | Reads (n)×2 words of data in units of 32 bits from the buffer memory areas of the intelligent function modules. |                               |
| DFROMDP            |                                                                                                                 |                               |

#### ■Writing 1-word/2-word data to a module (32-bit specification)

| Instruction symbol | Processing details                                                                                            | Reference                 |
|--------------------|---------------------------------------------------------------------------------------------------------------|---------------------------|
| TOD                | Writes (n) words of data in units of 32 bits to the buffer memory areas of the intelligent function module.   | Page 1021 TOD(P), DTOD(P) |
| TODP               |                                                                                                               |                           |
| DTOD               | Writes (n)×2 words of data in units of 32 bits to the buffer memory areas of the intelligent function module. |                           |
| DTODP              |                                                                                                               |                           |

#### ■Reading module specific information

| Instruction symbol | Processing details                                                        | Reference             |
|--------------------|---------------------------------------------------------------------------|-----------------------|
| UNIINFRD           | Stores module information in the device areas specified by (d) and later. | Page 1025 UNIINFRD(P) |
| UNIINFRDP          |                                                                           |                       |

## PID operation instruction

| Instruction symbol | Processing details                                                                                                                  | Reference     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------|
| PID                | Performs PID operation using the values set in (s1) to (s3), and stores the operation result in (d) at each cycle of sampling time. | Page 1041 PID |

## PID control instructions

### PID control instructions (inexact differential)

#### ■Registering the PID control data to the controller

| Instruction symbol | Processing details                                                                                                                                                      | Reference              |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| S.PIDINIT          | Stores the PID control data by the number of loops used that is set in the device number specified by (s) and later altogether in the controller to enable PID control. | Page 1056 S(P).PIDINIT |
| SP.PIDINIT         |                                                                                                                                                                         |                        |

#### ■Performing PID operation

| Instruction symbol | Processing details                                      | Reference              |
|--------------------|---------------------------------------------------------|------------------------|
| S.PIDCONT          | Measures the sampling cycle and performs PID operation. | Page 1059 S(P).PIDCONT |
| SP.PIDCONT         |                                                         |                        |

#### ■Stopping/starting the operation of specified loop number

| Instruction symbol | Processing details                                                          | Reference              |
|--------------------|-----------------------------------------------------------------------------|------------------------|

| PIDRUNP            |                                                                             |                      |

### ■Changing the parameters of specified loop number

| Instruction symbol | Processing details                                                                                                                                                  | Reference            |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| PIDPRMW            | Changes the operation parameter of the loop number in the device specified by (s1) to the PID control data stored in the device number specified by (s2) and later. | Page 1075 PIDPRMW(P) |
| PIDPRMWP           |                                                                                                                                                                     |                      |

## High-speed I/O control instructions

### Starting/stopping high-speed I/O

| Instruction symbol | Processing details                                                     | Reference           |
|--------------------|------------------------------------------------------------------------|---------------------|
| HIOEN(P)           | Controls the start and stop operations of the high-speed I/O function. | Page 1077 HIOEN(P)  |
| DHIOEN(P)          |                                                                        | Page 1080 DHIOEN(P) |

## Dedicated instructions for the positioning function

### Mechanical OPR

| Instruction symbol | Processing details               | Reference            |
|--------------------|----------------------------------|----------------------|
| DSZR               | Executes mechanical zero return. | Page 1083 DSZR/DDSZR |
| DDSZR              |                                  |                      |

### Interrupt 1-speed positioning

| Instruction symbol | Processing details                                 | Reference            |
|--------------------|----------------------------------------------------|----------------------|
| DVIT               | Executes interrupt 1-speed constant quantity feed. | Page 1090 DVIT/DDVIT |
| DDVIT              |                                                    |                      |

### Variable speed operation

| Instruction symbol | Processing details                                            | Reference            |
|--------------------|---------------------------------------------------------------|----------------------|
| PLSV               | Outputs variable speed pulses with rotation direction output. | Page 1096 PLSV/DPLSV |
| DPLSV              |                                                               |                      |

### 1-speed positioning (relative)

| Instruction symbol | Processing details                                    | Reference            |
|--------------------|-------------------------------------------------------|----------------------|
| DRVI               | Executes 1-speed positioning with a relative address. | Page 1101 DRVI/DDRVI |
| DDRVI              |                                                       |                      |

### 1-speed positioning (absolute)

| Instruction symbol | Processing details                                     | Reference            |
|--------------------|--------------------------------------------------------|----------------------|
| DRVA               | Executes 1-speed positioning with an absolute address. | Page 1106 DRVA/DDRVA |
| DDRVA              |                                                        |                      |

### Table operation (multiple tables)

| Instruction symbol | Processing details                                                                                                                                  | Reference        |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| DRVTBL             | Executes continuous operation or stepping operation for multiple tables with one instruction based on the table data set with the engineering tool. | Page 1111 DRVTBL |

### Interrupt input 1 trigger

| Instruction symbol | Processing details                                                                                       | Reference       |
|--------------------|----------------------------------------------------------------------------------------------------------|-----------------|
| DITRG              | Generates a trigger equivalent to the input interrupt 1 signal for triggering without using an X device. | Page 1113 DITRG |

### Absolute position restoration

| Instruction symbol | Processing details                                                                                                                                                                                                 | Reference        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| DABRST             | Reads the absolute position (ABS) data of a servo amplifier that supports the absolute position restoration function while the servo amplifier is being connected.<br>The data is converted into pulses when read. | Page 1116 DABRST |

## Dedicated instructions for the high-speed counter function

### 16-bit data read/write (update)

| Instruction symbol | Processing details                                                                                                               | Reference          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|--------------------|
| HCMOV(P)           | Reads and writes (updates) special relay/special register for high-speed counter, pulse width measurement, PWM, and positioning. | Page 1119 HCMOV(P) |

### 32-bit data read/write (update)

| Instruction symbol | Processing details                                                                                                               | Reference           |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|---------------------|
| DHCMOV(P)          | Reads and writes (updates) special relay/special register for high-speed counter, pulse width measurement, PWM, and positioning. | Page 1122 DHCMOV(P) |

## Pulse related instructions

### 16-bit binary pulse width modulation

| Instruction symbol | Processing details                                                                                                                                                            | Reference      |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| PWMH               | Outputs the ON time (in 16-bit data units) specified by (s1) and the pulse (in 16-bit data units) of the period specified by (s2) to the output destination specified by (d). | Page 1124 PWMH |

### 32-bit binary pulse width modulation

| Instruction symbol | Processing details                                                                                                                                                            | Reference       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| DPWMH              | Outputs the ON time (in 32-bit data units) specified by (s1) and the pulse (in 32-bit data units) of the period specified by (s2) to the output destination specified by (d). | Page 1131 DPWMH |

### Measuring the density of 16-bit data pulses

| Instruction symbol | Processing details                                                    | Reference      |
|--------------------|-----------------------------------------------------------------------|----------------|
| SPDH               | Measures the input pulse for the specified time with interrupt input. | Page 1138 SPDH |

### Measuring the density of 32-bit data pulses

| Instruction symbol | Processing details                                                    | Reference       |
|--------------------|-----------------------------------------------------------------------|-----------------|
| DSPDH              | Measures the input pulse for the specified time with interrupt input. | Page 1141 DSPDH |

## NETWORK INSTRUCTION LIST

### 7.1 Ethernet Instructions

#### Open/close processing instructions

##### ■Opening a connection

| Instruction symbol | Processing details                      | Reference                        |
|--------------------|-----------------------------------------|----------------------------------|
| GP.SOCOPEN         | Opens the connection specified by (s1). | Page 1146 GP.SOCOPEN, SP.SOCOPEN |
| SP.SOCOPEN         |                                         |                                  |

##### ■Closing a connection

| Instruction symbol | Processing details                                              | Reference                          |
|--------------------|-----------------------------------------------------------------|------------------------------------|
| GP.SOCCLOSE        | Closes the connection specified by (s1). (Closing a connection) | Page 1150 GP.SOCCLOSE, SP.SOCCLOSE |
| SP.SOCCLOSE        |                                                                 |                                    |

#### Socket communications instructions

##### ■Reading receive data during the END processing

| Instruction symbol | Processing details                                                                                                                | Reference                      |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| GP.SOCRCV          | Reads the receive data of the connection specified by (s1) during END processing from the socket communication receive data area. | Page 1152 GP.SOCRCV, SP.SOCRCV |
| SP.SOCRCV          |                                                                                                                                   |                                |

##### ■Reading receive data when the instruction is executed

| Instruction symbol | Processing details                                                                                                                      | Reference                      |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| G.SOCRCVS          | Reads the receive data of the connection specified by (s) during instruction execution from the socket communication receive data area. | Page 1157 G.SOCRCVS, S.SOCRCVS |
| S.SOCRCVS          |                                                                                                                                         |                                |

##### ■Sending data

| Instruction symbol | Processing details                                                                                         | Reference                      |
|--------------------|------------------------------------------------------------------------------------------------------------|--------------------------------|
| GP.SOCSND          | Sends the data in the device specified by (s3) to the external device of the connection specified by (s1). | Page 1160 GP.SOCSND, SP.SOCSND |
| SP.SOCSND          |                                                                                                            |                                |

##### ■Reading connection information

| Instruction symbol | Processing details                                                    | Reference                        |
|--------------------|-----------------------------------------------------------------------|----------------------------------|
| GP.SOCCINF         | Reads the connection information of the connection specified by (s1). | Page 1164 GP.SOCCINF, SP.SOCCINF |
| SP.SOCCINF         |                                                                       |                                  |

##### ■Changing the communication target (UDP/IP)

| Instruction symbol | Processing details                                                                                                            | Reference                        |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| GP.SOCCSET         | Changes the communication target IP address and port number of the connection specified by (s1). (UDP/IP communications only) | Page 1167 GP.SOCCSET, SP.SOCCSET |
| SP.SOCCSET         |                                                                                                                               |                                  |

## ■Changing the receive mode

| Instruction symbol | Processing details                                                                           | Reference                          |
|--------------------|----------------------------------------------------------------------------------------------|------------------------------------|
| GP.SOCRMODE        | Changes the TCP/TLS receive mode and receive data size for the connection specified by (s1). | Page 1169 GP.SOCRMODE, SP.SOCRMODE |
| SP.SOCRMODE        |                                                                                              |                                    |

## ■Reading socket communications receive data

| Instruction symbol | Processing details                                                                                                                                                                                | Reference                            |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| G.SOCRDATA         | Reads data by the number of words specified by (n) from the socket communication receive data area of the connection specified by (s1), and stores them in the device specified by (d) and later. | Page 1174 G(P).SOCDATA, S(P).SOCDATA |
| GP.SOCRDATA        |                                                                                                                                                                                                   |                                      |
| S.SOCRDATA         |                                                                                                                                                                                                   |                                      |
| SP.SOCRDATA        |                                                                                                                                                                                                   |                                      |

## Predefined protocol support function instruction

### ■Executing the registered protocols

| Instruction symbol | Processing details                                                                                  | Reference                        |
|--------------------|-----------------------------------------------------------------------------------------------------|----------------------------------|
| GP.ECPRTCL         | Executes the protocol specified by the communication protocol support tool of the engineering tool. | Page 1176 GP.ECPRTCL, SP.ECPRTCL |
| SP.ECPRTCL         |                                                                                                     |                                  |

## SLMP frame send instruction

### ■Sending an SLMP frame

| Instruction symbol | Processing details                                 | Reference                                        |
|--------------------|----------------------------------------------------|--------------------------------------------------|
| G.SLMPSND          | Sends SLMP messages to the SLMP-compatible device. | Page 1184 G(P).SLMPSND, J(P).SLMPSND, SP.SLMPSND |
| GP.SLMPSND         |                                                    |                                                  |
| J.SLMPSND          |                                                    |                                                  |
| JP.SLMPSND         |                                                    |                                                  |
| SP.SLMPSND         |                                                    |                                                  |

### ■Sending an encrypted SLMP frame

| Instruction symbol | Processing details                                           | Reference               |
|--------------------|--------------------------------------------------------------|-------------------------|

| GP.SLMPSNDC        |                                                              |                         |

## File transfer function instructions

### ■Sending FTP client files

| Instruction symbol | Processing details                                                                                                            | Reference                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| GP.FTPCPUT         | Sends files in the controller, which are specified by (s2), to the folder path of the FTP server, which is specified by (s3). | Page 1203 GP.FTPCPUT, SP.FTPPUT |
| SP.FTPPUT          |                                                                                                                               |                                 |

### ■Retrieving FTP client files

| Instruction symbol | Processing details                                                                                                                | Reference                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| GP.FTPCGET         | Retrieves files on the FTP server, which are specified by (s2), to the folder path of the controller, which is specified by (s3). | Page 1209 GP.FTPCGET, SP.FTPGET |
| SP.FTPGET          |                                                                                                                                   |                                 |

## 7.2 External Device Communication Instructions

### Special adapter instructions

| Instruction symbol | Processing details                                                                                                     | Reference       |
|--------------------|------------------------------------------------------------------------------------------------------------------------|-----------------|
| ADPRW              | Allows for communications (data read/write) with slave stations using function codes that are supported by the master. | Page 1215 ADPRW |

### Serial data transmission 2

| Instruction symbol | Processing details                                                                                           | Reference     |
|--------------------|--------------------------------------------------------------------------------------------------------------|---------------|
| RS2                | Sends/receives data by non-protocol communication via the communication adapter installed on the controller. | Page 1219 RS2 |

How to read the list is shown below.

| Item                                      | Description                                                    |
|-------------------------------------------|----------------------------------------------------------------|
| Function symbol and function block symbol | A function and function block name are shown.                  |
| Processing details                        | An overview of the functions and function blocks is explained. |
| Reference                                 | Indicates the reference of detailed information.               |

## 8.1 Standard Functions

### Type conversion functions

#### ■Converting BOOL to WORD/DWORD

| Function symbol | Processing details                                       | Reference                      |
|-----------------|----------------------------------------------------------|--------------------------------|
| BOOL_TO_WORD    | Converts a value from BOOL data type to WORD data type.  | Page 1222<br>BOOL_TO_WORD(_E)  |
| BOOL_TO_WORD_E  |                                                          |                                |
| BOOL_TO_DWORD   | Converts a value from BOOL data type to DWORD data type. | Page 1223<br>BOOL_TO_DWORD(_E) |
| BOOL_TO_DWORD_E |                                                          |                                |

#### ■Converting BOOL to INT/DINT

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| BOOL_TO_INT     | Converts a value from BOOL data type to INT data type.  | Page 1224 BOOL_TO_INT(_E)     |
| BOOL_TO_INT_E   |                                                         |                               |
| BOOL_TO_DINT    | Converts a value from BOOL data type to DINT data type. | Page 1225<br>BOOL_TO_DINT(_E) |
| BOOL_TO_DINT_E  |                                                         |                               |

#### ■Converting BOOL to TIME

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| BOOL_TO_TIME    | Converts a value from BOOL data type to TIME data type. | Page 1226<br>BOOL_TO_TIME(_E) |
| BOOL_TO_TIME_E  |                                                         |                               |

#### ■Converting BOOL to STRING

| Function symbol  | Processing details                                        | Reference                       |
|------------------|-----------------------------------------------------------|---------------------------------|
| BOOL_TO_STRING   | Converts a value from BOOL data type to STRING data type. | Page 1227<br>BOOL_TO_STRING(_E) |
| BOOL_TO_STRING_E |                                                           |                                 |

#### ■Converting WORD to BOOL

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| WORD_TO_BOOL    | Converts a value from WORD data type to BOOL data type. | Page 1228<br>WORD_TO_BOOL(_E) |
| WORD_TO_BOOL_E  |                                                         |                               |

#### ■Converting WORD to DWORD

| Function symbol | Processing details                                       | Reference                      |
|-----------------|----------------------------------------------------------|--------------------------------|
| WORD_TO_DWORD   | Converts a value from WORD data type to DWORD data type. | Page 1229<br>WORD_TO_DWORD(_E) |
| WORD_TO_DWORD_E |                                                          |                                |

## ■Converting WORD to INT/DINT

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| WORD_TO_INT     | Converts a value from WORD data type to INT data type.  | Page 1230<br>WORD_TO_INT(_E)  |
| WORD_TO_INT_E   |                                                         |                               |
| WORD_TO_DINT    | Converts a value from WORD data type to DINT data type. | Page 1231<br>WORD_TO_DINT(_E) |
| WORD_TO_DINT_E  |                                                         |                               |

## ■Converting WORD to TIME

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| WORD_TO_TIME    | Converts a value from WORD data type to TIME data type. | Page 1232<br>WORD_TO_TIME(_E) |
| WORD_TO_TIME_E  |                                                         |                               |

## ■Converting WORD to STRING

| Function symbol  | Processing details                                        | Reference                       |
|------------------|-----------------------------------------------------------|---------------------------------|
| WORD_TO_STRING   | Converts a value from WORD data type to STRING data type. | Page 1233<br>WORD_TO_STRING(_E) |
| WORD_TO_STRING_E |                                                           |                                 |

## ■Converting DWORD to BOOL

| Function symbol | Processing details                                       | Reference                      |
|-----------------|----------------------------------------------------------|--------------------------------|
| DWORD_TO_BOOL   | Converts a value from DWORD data type to BOOL data type. | Page 1234<br>DWORD_TO_BOOL(_E) |
| DWORD_TO_BOOL_E |                                                          |                                |

## ■Converting DWORD to WORD

| Function symbol | Processing details                                       | Reference                      |
|-----------------|----------------------------------------------------------|--------------------------------|
| DWORD_TO_WORD   | Converts a value from DWORD data type to WORD data type. | Page 1235<br>DWORD_TO_WORD(_E) |
| DWORD_TO_WORD_E |                                                          |                                |

## ■Converting DWORD to INT/DINT

| Function symbol | Processing details                                       | Reference                      |
|-----------------|----------------------------------------------------------|--------------------------------|
| DWORD_TO_INT    | Converts a value from DWORD data type to INT data type.  | Page 1237<br>DWORD_TO_INT(_E)  |
| DWORD_TO_INT_E  |                                                          |                                |
| DWORD_TO_DINT   | Converts a value from DWORD data type to DINT data type. | Page 1239<br>DWORD_TO_DINT(_E) |
| DWORD_TO_DINT_E |                                                          |                                |

## ■Converting DWORD to TIME

| Function symbol | Processing details                                       | Reference                      |
|-----------------|----------------------------------------------------------|--------------------------------|
| DWORD_TO_TIME   | Converts a value from DWORD data type to TIME data type. | Page 1240<br>DWORD_TO_TIME(_E) |
| DWORD_TO_TIME_E |                                                          |                                |

## ■Converting DWORD to STRING

| Function symbol   | Processing details                                         | Reference                        |
|-------------------|------------------------------------------------------------|----------------------------------|
| DWORD_TO_STRING   | Converts a value from DWORD data type to STRING data type. | Page 1241<br>DWORD_TO_STRING(_E) |
| DWORD_TO_STRING_E |                                                            |                                  |

## ■Converting INT to BOOL

| Function symbol | Processing details                                     | Reference                 |
|-----------------|--------------------------------------------------------|---------------------------|
| INT_TO_BOOL     | Converts a value from INT data type to BOOL data type. | Page 1242 INT_TO_BOOL(_E) |
| INT_TO_BOOL_E   |                                                        |                           |

## ■Converting INT to WORD/DWORD

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| INT_TO_WORD     | Converts a value from INT data type to WORD data type.  | Page 1243<br>INT_TO_WORD(_E)  |
| INT_TO_WORD_E   |                                                         |                               |
| INT_TO_DWORD    | Converts a value from INT data type to DWORD data type. | Page 1244<br>INT_TO_DWORD(_E) |
| INT_TO_DWORD_E  |                                                         |                               |

## ■Converting INT to DINT

| Function symbol | Processing details                                     | Reference                 |
|-----------------|--------------------------------------------------------|---------------------------|
| INT_TO_DINT     | Converts a value from INT data type to DINT data type. | Page 1245 INT_TO_DINT(_E) |
| INT_TO_DINT_E   |                                                        |                           |

## ■Converting INT to BCD

| Function symbol | Processing details                                    | Reference                |
|-----------------|-------------------------------------------------------|--------------------------|
| INT_TO_BCD      | Converts a value from INT data type to BCD data type. | Page 1246 INT_TO_BCD(_E) |
| INT_TO_BCD_E    |                                                       |                          |

## ■Converting INT to REAL/LREAL

| Function symbol | Processing details                                      | Reference                     |
|-----------------|---------------------------------------------------------|-------------------------------|
| INT_TO_REAL     | Converts a value from INT data type to REAL data type.  | Page 1248 INT_TO_REAL(_E)     |
| INT_TO_REAL_E   |                                                         |                               |
| INT_TO_LREAL    | Converts a value from INT data type to LREAL data type. | Page 1249<br>INT_TO_LREAL(_E) |
| INT_TO_LREAL_E  |                                                         |                               |

## ■Converting INT to TIME

| Function symbol | Processing details                                     | Reference                 |
|-----------------|--------------------------------------------------------|---------------------------|
| INT_TO_TIME     | Converts a value from INT data type to TIME data type. | Page 1250 INT_TO_TIME(_E) |
| INT_TO_TIME_E   |                                                        |                           |

## ■Converting INT to STRING

| INT_TO_BITARR    | Outputs the lower n bits of the INT data type value to the bit array.  | Page 1306<br>INT_TO_BITARR(_E)  |
| INT_TO_BITARR_E  |                                                                        |                                 |
| DINT_TO_BITARR   | Outputs the lower n bits of the DINT data type value to the bit array. | Page 1307<br>DINT_TO_BITARR(_E) |
| DINT_TO_BITARR_E |                                                                        |                                 |

## ■Copying the bit array

| Function symbol | Processing details                                    | Reference                   |
|-----------------|-------------------------------------------------------|-----------------------------|
| CPY_BITARR      | Copies the bit array by the specified number of bits. | Page 1308<br>CPY_BITARR(_E) |
| CPY_BITARR_E    |                                                       |                             |

## ■Reading/writing/copying the specified bit of the word label

| Function symbol  | Processing details                                                                     | Reference                       |
|------------------|----------------------------------------------------------------------------------------|---------------------------------|
| GET_BIT_OF_INT   | Reads a value from the specified bit of a word label.                                  | Page 1309<br>GET_BIT_OF_INT(_E) |
| GET_BIT_OF_INT_E |                                                                                        |                                 |
| SET_BIT_OF_INT   | Writes a value to the specified bit of a word label.                                   | Page 1311<br>SET_BIT_OF_INT(_E) |
| SET_BIT_OF_INT_E |                                                                                        |                                 |
| CPY_BIT_OF_INT   | Copies the specified bit of the word label to the specified bit of another word label. | Page 1313<br>CPY_BIT_OF_INT(_E) |
| CPY_BIT_OF_INT_E |                                                                                        |                                 |

## ■Getting the start data

| Function symbol | Processing details                                                              | Reference                                                     |
|-----------------|---------------------------------------------------------------------------------|---------------------------------------------------------------|
| GET_BOOL_ADDR   | Outputs the top data of the specified data as the BOOL, INT, or WORD type data. | Page 1315<br>GET_BOOL_ADDR,<br>GET_INT_ADDR,<br>GET_WORD_ADDR |
| GET_INT_ADDR    |                                                                                 |                                                               |
| GET_WORD_ADDR   |                                                                                 |                                                               |

## Single variable functions

### ■Calculating the absolute value

| Function symbol | Processing details                            | Reference         |
|-----------------|-----------------------------------------------|-------------------|
| ABS             | Outputs the absolute value of an input value. | Page 1316 ABS(_E) |
| ABS_E           |                                               |                   |

### ■Calculating the square root

| Function symbol | Processing details                            | Reference          |
|-----------------|-----------------------------------------------|--------------------|
| SQRT            | Calculates the square root of an input value. | Page 1318 SQRT(_E) |
| SQRT_E          |                                               |                    |

### ■Calculating the natural logarithm

| Function symbol | Processing details                                                       | Reference        |
|-----------------|--------------------------------------------------------------------------|------------------|
| LN              | Outputs the natural logarithm (logarithm with base e) of an input value. | Page 1319 LN(_E) |
| LN_E            |                                                                          |                  |

### ■Calculating the common logarithm

| Function symbol | Processing details                                                       | Reference         |
|-----------------|--------------------------------------------------------------------------|-------------------|
| LOG             | Outputs the common logarithm (logarithm with base 10) of an input value. | Page 1320 LOG(_E) |
| LOG_E           |                                                                          |                   |

### ■Calculating the exponent

| Function symbol | Processing details                      | Reference         |
|-----------------|-----------------------------------------|-------------------|
| EXP             | Outputs the exponent of an input value. | Page 1322 EXP(_E) |
| EXP_E           |                                         |                   |

### ■Calculating the sine/cosine/tangent

| Function symbol | Processing details                     | Reference         |
|-----------------|----------------------------------------|-------------------|
| SIN             | Outputs the sine of an input value.    | Page 1323 SIN(_E) |
| SIN_E           |                                        |                   |
| COS             | Outputs the cosine of an input value.  | Page 1324 COS(_E) |
| COS_E           |                                        |                   |
| TAN             | Outputs the tangent of an input value. | Page 1325 TAN(_E) |
| TAN_E           |                                        |                   |

### ■Calculating the arc sine/arc cosine/arc tangent

| Function symbol | Processing details                                               | Reference          |
|-----------------|------------------------------------------------------------------|--------------------|
| ASIN            | Outputs the arc sine ( $\text{SIN}^{-1}$ ) of an input value.    | Page 1326 ASIN(_E) |
| ASIN_E          |                                                                  |                    |
| ACOS            | Outputs the arc cosine ( $\text{COS}^{-1}$ ) of an input value.  | Page 1327 ACOS(_E) |
| ACOS_E          |                                                                  |                    |
| ATAN            | Outputs the arc tangent ( $\text{TAN}^{-1}$ ) of an input value. | Page 1328 ATAN(_E) |
| ATAN_E          |                                                                  |                    |

## Arithmetic operation functions

### ■ Addition

| Function symbol | Processing details                                          | Reference         |
|-----------------|-------------------------------------------------------------|-------------------|
| ADD             | Outputs the sum of input values $((s1)+(s2)+\dots+(s28))$ . | Page 1329 ADD(_E) |
| ADD_E           |                                                             |                   |

### ■ Multiplication

| Function symbol | Processing details                                                             | Reference         |
|-----------------|--------------------------------------------------------------------------------|-------------------|
| MUL             | Outputs the product of input values $((s1)\times(s2)\times\dots\times(s28))$ . | Page 1332 MUL(_E) |
| MUL_E           |                                                                                |                   |

### ■ Subtraction

| Function symbol | Processing details                                          | Reference         |
|-----------------|-------------------------------------------------------------|-------------------|
| SUB             | Outputs the difference between input values $((s1)-(s2))$ . | Page 1335 SUB(_E) |
| SUB_E           |                                                             |                   |

### ■ Division

| Function symbol | Processing details                                      | Reference         |
|-----------------|---------------------------------------------------------|-------------------|
| DIV             | Outputs the quotient of input values $((s1)\div(s2))$ . | Page 1338 DIV(_E) |
| DIV_E           |                                                         |                   |

### ■ Remainder

| Function symbol | Processing details                                       | Reference         |
|-----------------|----------------------------------------------------------|-------------------|
| MOD             | Outputs the remainder of input values $((s1)\div(s2))$ . | Page 1340 MOD(_E) |
| MOD_E           |                                                          |                   |

### ■ Exponentiation

| Function symbol | Processing details                            | Reference          |
|-----------------|-----------------------------------------------|--------------------|
| EXPT            | Outputs the exponentiation of an input value. | Page 1342 EXPT(_E) |
| EXPT_E          |                                               |                    |

### ■ Assignment (move operation)

| Function symbol | Processing details                              | Reference          |
|-----------------|-------------------------------------------------|--------------------|
| MOVE            | Outputs the assignment value of an input value. | Page 1344 MOVE(_E) |
| MOVE_E          |                                                 |                    |

## Bit shift functions

### ■ Shifting data to the left/right by n bit(s)

| Function symbol | Processing details                                                                   | Reference         |
|-----------------|--------------------------------------------------------------------------------------|-------------------|
| SHL             | Shifts the input value to the left by (n) bit(s), and outputs the operation result.  | Page 1346 SHL(_E) |
| SHL_E           |                                                                                      |                   |
| SHR             | Shifts the input value to the right by (n) bit(s), and outputs the operation result. | Page 1348 SHR(_E) |
| SHR_E           |                                                                                      |                   |

### ■ Rotating data to the left/right by n bit(s)

| Function symbol | Processing details                                                                    | Reference         |
|-----------------|---------------------------------------------------------------------------------------|-------------------|
| ROL             | Rotates the input value to the left by (n) bit(s), and outputs the operation result.  | Page 1350 ROL(_E) |
| ROL_E           |                                                                                       |                   |
| ROR             | Rotates the input value to the right by (n) bit(s), and outputs the operation result. | Page 1352 ROR(_E) |
| ROR_E           |                                                                                       |                   |

## Boolean functions

### ■AND operation, OR operation, XOR operation

| Function symbol | Processing details                                 | Reference                          |
|-----------------|----------------------------------------------------|------------------------------------|
| AND             | Outputs the logical product of input values.       | Page 1354 AND(_E), OR(_E), XOR(_E) |
| AND_E           |                                                    |                                    |
| OR              | Outputs the logical sum of input values.           |                                    |
| OR_E            |                                                    |                                    |
| XOR             | Outputs the exclusive logical sum of input values. |                                    |
| XOR_E           |                                                    |                                    |

### ■NOT operation

| Function symbol | Processing details                       | Reference         |
|-----------------|------------------------------------------|-------------------|
| NOT             | Outputs the logical NOT of input values. | Page 1357 NOT(_E) |
| NOT_E           |                                          |                   |

## Selection functions

### ■Selecting a value

| Function symbol | Processing details                | Reference         |
|-----------------|-----------------------------------|-------------------|
| SEL             | Outputs the selected input value. | Page 1358 SEL(_E) |
| SEL_E           |                                   |                   |

### ■Selecting the maximum/minimum value

| Function symbol | Processing details               | Reference                  |
|-----------------|----------------------------------|----------------------------|
| MAX             | Outputs the maximum input value. | Page 1360 MAX(_E), MIN(_E) |
| MAX_E           |                                  |                            |
| MIN             | Outputs the minimum input value. |                            |
| MIN_E           |                                  |                            |

### ■Controlling the upper/lower limit

| Function symbol | Processing details                                                                      | Reference           |
|-----------------|-----------------------------------------------------------------------------------------|---------------------|
| LIMIT           | Outputs an input value that has been controlled in terms of the upper and lower limits. | Page 1362 LIMIT(_E) |
| LIMIT_E         |                                                                                         |                     |

### ■Multiplexer

| Function symbol | Processing details               | Reference         |
|-----------------|----------------------------------|-------------------|
| MUX             | Outputs one of the input values. | Page 1365 MUX(_E) |
| MUX_E           |                                  |                   |

## Comparison functions

### ■Comparing data

| Function symbol | Processing details                             | Reference                                        |
|-----------------|------------------------------------------------|--------------------------------------------------|
| GT              | Outputs the comparison result of input values. | Page 1367 GT(_E), GE(_E), EQ(_E), LE(_E), LT(_E) |
| GT_E            |                                                |                                                  |
| GE              |                                                |                                                  |
| GE_E            |                                                |                                                  |
| EQ              |                                                |                                                  |
| EQ_E            |                                                |                                                  |
| LE              |                                                |                                                  |
| LE_E            |                                                |                                                  |
| LT              |                                                |                                                  |
| LT_E            |                                                |                                                  |
| NE              |                                                | Page 1369 NE(_E)                                 |

## String functions

### ■Detecting a string length

| Function symbol | Processing details                                  | Reference         |
|-----------------|-----------------------------------------------------|-------------------|
| LEN             | Detects and outputs the length of the string input. | Page 1371 LEN(_E) |
| LEN_E           |                                                     |                   |

### ■Extracting string data from the left/right

| Function symbol | Processing details                                                                                        | Reference                     |
|-----------------|-----------------------------------------------------------------------------------------------------------|-------------------------------|
| LEFT            | Extracts and outputs the specified number of characters, starting from the left end of the string input.  | Page 1373 LEFT(_E), RIGHT(_E) |
| LEFT_E          |                                                                                                           |                               |
| RIGHT           | Extracts and outputs the specified number of characters, starting from the right end of the string input. |                               |
| RIGHT_E         |                                                                                                           |                               |

### ■Extracting string data

| Function symbol | Processing details                                                                                                 | Reference         |
|-----------------|--------------------------------------------------------------------------------------------------------------------|-------------------|
| MID             | Extracts and outputs the specified number of characters, starting from the specified position of the string input. | Page 1376 MID(_E) |
| MID_E           |                                                                                                                    |                   |

### ■Concatenating string data

| Function symbol | Processing details                                      | Reference            |
|-----------------|---------------------------------------------------------|----------------------|
| CONCAT          | Concatenates strings, and outputs the operation result. | Page 1378 CONCAT(_E) |
| CONCAT_E        |                                                         |                      |

### ■Inserting string data

| Function symbol | Processing details                                                      | Reference            |
|-----------------|-------------------------------------------------------------------------|----------------------|
| INSERT          | Inserts a string into another string, and outputs the operation result. | Page 1380 INSERT(_E) |
| INSERT_E        |                                                                         |                      |

### ■Deleting string data

| Function symbol | Processing details                                                         | Reference            |
|-----------------|----------------------------------------------------------------------------|----------------------|
| DELETE          | Deletes the specified range in a string, and outputs the operation result. | Page 1382 DELETE(_E) |
| DELETE_E        |                                                                            |                      |

## ■Replacing string data

| Function symbol | Processing details                                                          | Reference             |
|-----------------|-----------------------------------------------------------------------------|-----------------------|
| REPLACE         | Replaces the specified range in a string, and outputs the operation result. | Page 1384 REPLACE(_E) |
| REPLACE_E       |                                                                             |                       |

## ■Searching string data

| Function symbol | Processing details                                   | Reference          |
|-----------------|------------------------------------------------------|--------------------|
| FIND            | Searches a string, and outputs the operation result. | Page 1387 FIND(_E) |
| FIND_E          |                                                      |                    |

## Time data type functions

### ■Addition

| Function symbol | Processing details                                                | Reference              |
|-----------------|-------------------------------------------------------------------|------------------------|
| ADD_TIME        | Outputs the sum $((s1)+(s2))$ of the TIME data type input values. | Page 1389 ADD_TIME(_E) |
| ADD_TIME_E      |                                                                   |                        |

### ■Subtraction

| Function symbol | Processing details                                                            | Reference              |
|-----------------|-------------------------------------------------------------------------------|------------------------|
| SUB_TIME        | Outputs the difference $((s1)-(s2))$ between the TIME data type input values. | Page 1391 SUB_TIME(_E) |
| SUB_TIME_E      |                                                                               |                        |

### ■Multiplication

| Function symbol | Processing details                                                         | Reference              |
|-----------------|----------------------------------------------------------------------------|------------------------|
| MUL_TIME        | Outputs the product $((s1)\times(s2))$ of the TIME data type input values. | Page 1393 MUL_TIME(_E) |
| MUL_TIME_E      |                                                                            |                        |

### ■Division

| Function symbol | Processing details                                                        | Reference              |
|-----------------|---------------------------------------------------------------------------|------------------------|
| DIV_TIME        | Outputs the quotient $((s1)\div(s2))$ of the TIME data type input values. | Page 1395 DIV_TIME(_E) |
| DIV_TIME_E      |                                                                           |                        |

## 8.2 Standard Function Blocks

### Bistable function blocks

#### ■ Bistable function block (set-dominant)

| Function block symbol | Processing details                                                        | Reference        |
|-----------------------|---------------------------------------------------------------------------|------------------|
| SR                    | Discriminates between two input values, and outputs1 (TRUE) or 0 (FALSE). | Page 1398 SR(_E) |
| SR_E                  |                                                                           |                  |

#### ■ Bistable function block (reset-dominant)

| Function block symbol | Processing details                                                        | Reference        |
|-----------------------|---------------------------------------------------------------------------|------------------|
| RS                    | Discriminates between two input values, and outputs1 (TRUE) or 0 (FALSE). | Page 1400 RS(_E) |
| RS_E                  |                                                                           |                  |

### Edge detection function blocks

#### ■ Detecting a rising edge

| Function block symbol | Processing details                                          | Reference            |
|-----------------------|-------------------------------------------------------------|----------------------|
| R_TRIG                | Detects a signal rising edge, and outputs the pulse signal. | Page 1402 R_TRIG(_E) |
| R_TRIG_E              |                                                             |                      |

#### ■ Detecting a falling edge

| Function block symbol | Processing details                                           | Reference            |
|-----------------------|--------------------------------------------------------------|----------------------|
| F_TRIG                | Detects a signal falling edge, and outputs the pulse signal. | Page 1404 F_TRIG(_E) |
| F_TRIG_E              |                                                              |                      |

### Counter function blocks

#### ■ Up counter

| Function block symbol | Processing details                                | Reference         |
|-----------------------|---------------------------------------------------|-------------------|
| CTU                   | Counts up the number of rising edges of a signal. | Page 1406 CTU(_E) |
| CTU_E                 |                                                   |                   |

#### ■ Down counter

| Function block symbol | Processing details                                  | Reference         |
|-----------------------|-----------------------------------------------------|-------------------|
| CTD                   | Counts down the number of rising edges of a signal. | Page 1408 CTD(_E) |
| CTD_E                 |                                                     |                   |

#### ■ Up/down counter

| Function block symbol | Processing details                                        | Reference          |
|-----------------------|-----------------------------------------------------------|--------------------|
| CTUD                  | Counts up or down the number of rising edges of a signal. | Page 1410 CTUD(_E) |
| CTUD_E                |                                                           |                    |

#### ■ Counter function block

| Function block symbol | Processing details                                            | Reference              |
|-----------------------|---------------------------------------------------------------|------------------------|
| COUNTER_FB_M          | Starts counting up when the execution condition is satisfied. | Page 1413 COUNTER_FB_M |

## Timer function blocks

### ■Pulse timer

| Function block symbol | Processing details                                    | Reference        |
|-----------------------|-------------------------------------------------------|------------------|
| TP                    | Keeps the signal on for the specified period of time. | Page 1415 TP(_E) |
| TP_E                  |                                                       |                  |

### ■On delay timer

| Function block symbol | Processing details                                    | Reference         |
|-----------------------|-------------------------------------------------------|-------------------|
| TON                   | Turns on a signal after the specified period of time. | Page 1418 TON(_E) |
| TON_E                 |                                                       |                   |

### ■Off delay timer

| Function block symbol | Processing details                                     | Reference         |
|-----------------------|--------------------------------------------------------|-------------------|
| TOF                   | Turns off a signal after the specified period of time. | Page 1420 TOF(_E) |
| TOF_E                 |                                                        |                   |

### ■Timer function block

| Function block symbol | Processing details                                                                                                               | Reference           |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------|---------------------|
| TIMER_10_FB_M         | Starts counting a timer when the execution condition is satisfied, and continues counting until the timer reaches the set value. | Page 1422 TIMER_□_M |
| TIMER_100_FB_M        |                                                                                                                                  |                     |
| TIMER_HIGH_FB_M       |                                                                                                                                  |                     |
| TIMER_LOW_FB_M        |                                                                                                                                  |                     |
| TIMER_CONT_FB_M       |                                                                                                                                  |                     |
| TIMER_CONTHFB_M       |                                                                                                                                  |                     |

This chapter describes how to read the list.

| Item                  | Description                                  |
|-----------------------|----------------------------------------------|
| Function block symbol | Shows the function block name.               |
| Processing details    | Shows an overview of the function block.     |
| Reference             | Shows the reference of detailed information. |

For an overview on the motion control function block, refer to the following.

 Page 1428 MOTION CONTROL FB OVERVIEW

## 9.1 Administrative Function Blocks

The list of administrative motion control function blocks is shown below.

### Axes Group Enabled

| Function block symbol | Processing details                                                                                                    | Reference                    |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------|------------------------------|
| MC_GroupEnable        | Changes the specified Axes group status from "0: Axes group disabled (GroupDisabled)" to "4: Standby (GroupStandby)". | Page 1528 Axes Group Enabled |

### Axes Group Disabled

| Function block symbol | Processing details                                                                   | Reference                     |
|-----------------------|--------------------------------------------------------------------------------------|-------------------------------|
| MC_GroupDisable       | Changes the specified axes group status to "0: Axes group disabled (GroupDisabled)". | Page 1532 Axes Group Disabled |

### Operation Available

| Function block symbol | Processing details                                           | Reference          |
|-----------------------|--------------------------------------------------------------|--------------------|
| MC_Power              | Switches a specified axis to the operation available status. | Page 1536 Operable |

### Current Position Change

| Function block symbol | Processing details                                                                        | Reference                         |
|-----------------------|-------------------------------------------------------------------------------------------|-----------------------------------|
| MC_SetPosition        | Changes the current position (commanded position, actual position) of the specified axis. | Page 1540 Current Position Change |

### Torque Limit Value

| Function block symbol | Processing details            | Reference                    |
|-----------------------|-------------------------------|------------------------------|
| MCv_SetTorqueLimit    | Changes a torque limit value. | Page 1548 Torque Limit Value |

### Override Value Setting

| Function block symbol | Processing details                                                                                       | Reference                        |
|-----------------------|----------------------------------------------------------------------------------------------------------|----------------------------------|
| MC_SetOverride        | Changes the target velocity, the target acceleration, and the target deceleration of the specified axis. | Page 1556 Override Value Setting |

## Parameter Read

| Function block symbol | Processing details         | Reference                |
|-----------------------|----------------------------|--------------------------|
| MC_ReadParameter      | Reads objects of a device. | Page 1561 Parameter Read |

## Parameter Write

| Function block symbol | Processing details          | Reference                 |
|-----------------------|-----------------------------|---------------------------|
| MC_WriteParameter     | Writes objects of a device. | Page 1568 Parameter Write |

## Axis Error Reset

| Function block symbol | Processing details                      | Reference                  |
|-----------------------|-----------------------------------------|----------------------------|
| MC_Reset              | Resets errors and warnings of the axis. | Page 1574 Axis Error Reset |

## Axes Group Error Reset

| Function block symbol | Processing details                                                            | Reference                        |
|-----------------------|-------------------------------------------------------------------------------|----------------------------------|
| MC_GroupReset         | Resets errors and warnings of the axes group and each axis in the axes group. | Page 1577 Axes Group Error Reset |

## Touch Probe Enabled

| Function block symbol | Processing details                                 | Reference                     |
|-----------------------|----------------------------------------------------|-------------------------------|
| MC_TouchProbe         | Records optional data when a trigger event occurs. | Page 1581 Touch Probe Enabled |

## Touch Probe Disabled

| Function block symbol | Processing details                         | Reference                      |
|-----------------------|--------------------------------------------|--------------------------------|
| MC_AbortTrigger       | Disables the latch that is being executed. | Page 1596 Touch Probe Disabled |

## Cam Table Selection

| Function block symbol | Processing details                                                         | Reference                     |
|-----------------------|----------------------------------------------------------------------------|-------------------------------|
| MC_CamTableSelect     | Stores the specified operation profile data (cam data) into the open area. | Page 1602 Cam Table Selection |

## Current Value Change per Cycle

| Function block symbol | Processing details                                                                      | Reference                                |
|-----------------------|-----------------------------------------------------------------------------------------|------------------------------------------|
| MCv_ChangeCycle       | Changes the current value per cycle of the specified operation profile data control FB. | Page 1611 Current Value Change per Cycle |

## All Axes Operation Available

| Function block symbol | Processing details                                     | Reference                              |
|-----------------------|--------------------------------------------------------|----------------------------------------|
| MCv_AllPower          | Switches every axis to the operation available status. | Page 1619 All Axes Operation Available |

## Axes Group Override Value Setting

| Function block symbol | Processing details                                                                                             | Reference                                   |
|-----------------------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| MC_GroupSetOverride   | Changes the target velocity, the target acceleration, and the target deceleration of the specified axes group. | Page 1622 Axes Group Override Value Setting |

## Motion Error Reset

| Function block symbol | Processing details                                   | Reference                    |
|-----------------------|------------------------------------------------------|------------------------------|
| MCv_MotionErrorReset  | Resets all errors and warnings of the Motion system. | Page 1627 Motion Error Reset |

## Control Operation Cycle Synchronization

| Function block symbol   | Processing details                                                             | Reference                                         |
|-------------------------|--------------------------------------------------------------------------------|---------------------------------------------------|
| MCv_SyncOperationCycles | Synchronizes the control operation cycle of the axis with the specified cycle. | Page 1631 Control Operation Cycle Synchronization |

## Advanced Synchronous Control Current Position per Cycle Calculation

| Function block symbol       | Processing details                                                         | Reference                                                                     |
|-----------------------------|----------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| MCv_AdvPositionPerCycleCalc | Calculates the current position per cycle based on the specified cam data. | Page 1634 Advanced Synchronous Control One Cycle Current Position Calculation |

## Advanced Synchronous Control Cam Set Position Calculation

| Function block symbol     | Processing details                                               | Reference                                                              |
|---------------------------|------------------------------------------------------------------|------------------------------------------------------------------------|
| MCv_AdvCamSetPositionCalc | Calculates the cam set position based on the specified cam data. | Page 1637 Cam Set Position Calculation in Advanced Synchronous Control |

## Digital Cam Switch Output

| Function block symbol | Processing details                                          | Reference                           |
|-----------------------|-------------------------------------------------------------|-------------------------------------|
| MC_DigitalCamSwitch   | Outputs the on/off signals according to a given data value. | Page 1640 Digital Cam Switch Output |

## 9.2 Motion Function Blocks

The list of motion related motion control function blocks is shown below.

### OPR

| Function block symbol | Processing details                      | Reference        |
|-----------------------|-----------------------------------------|------------------|
| MC_Home               | Executes homing for the specified axis. | Page 1647 Homing |

### Forced Stop

| Function block symbol | Processing details                        | Reference             |
|-----------------------|-------------------------------------------|-----------------------|
| MC_Stop               | Decelerates the specified axis to a stop. | Page 1658 Forced Stop |

### Group Forced Stop

| Function block symbol | Processing details                              | Reference                   |
|-----------------------|-------------------------------------------------|-----------------------------|
| MC_GroupStop          | Decelerates the specified axes group to a stop. | Page 1663 Group Forced Stop |

### Absolute Value Positioning

| Function block symbol | Processing details                                                          | Reference                            |
|-----------------------|-----------------------------------------------------------------------------|--------------------------------------|
| MC_MoveAbsolute       | Sets the target position of the absolute position and performs positioning. | Page 1669 Absolute Value Positioning |

### Relative Value Positioning

| Function block symbol | Processing details                                                          | Reference                            |
|-----------------------|-----------------------------------------------------------------------------|--------------------------------------|
| MC_MoveRelative       | Sets the movement amount of the relative position and performs positioning. | Page 1682 Relative Value Positioning |

### JOG

| Function block symbol | Processing details                                        | Reference               |
|-----------------------|-----------------------------------------------------------|-------------------------|
| MCv_Jog               | Executes JOG operation according to the command velocity. | Page 1692 JOG Operation |

### Speed Control

| Function block symbol | Processing details                                                                                | Reference               |
|-----------------------|---------------------------------------------------------------------------------------------------|-------------------------|
| MC_MoveVelocity       | Switches the drive unit to csv and performs velocity control according to the specified velocity. | Page 1702 Speed Control |

### Torque Control

| Function block symbol | Processing details                                                                                   | Reference                |
|-----------------------|------------------------------------------------------------------------------------------------------|--------------------------|
| MC_TorqueControl      | Switches the drive unit to cst and performs torque control according to the specified target torque. | Page 1710 Torque Control |

### Speed Control (Including Position Loop)

| Function block symbol | Processing details                                  | Reference                                         |
|-----------------------|-----------------------------------------------------|---------------------------------------------------|
| MCv_SpeedControl      | Performs speed control including the position loop. | Page 1721 Speed Control (Including Position Loop) |

## Absolute Value Linear Interpolation Control

| Function block symbol             | Processing details                                                                                                                     | Reference                                             |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| MCv_MoveLinearInterpolateAbsolute | Specifies the target position of the absolute position of the set axes group and performs positioning by linear interpolation control. | Page 1730 Absolute Value Linear Interpolation Control |

## Relative Value Linear Interpolation Control

| Function block symbol             | Processing details                                                                                                                     | Reference                                             |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| MCv_MoveLinearInterpolateRelative | Specifies the movement amount of the relative position of the set axes group and performs positioning by linear interpolation control. | Page 1745 Relative Value Linear Interpolation Control |

## Absolute Value Circular Interpolation Control

| Function block symbol               | Processing details                                                                                                                                                          | Reference                                               |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| MCv_MoveCircularInterpolateAbsolute | Performs positioning with 2-axis circular interpolation using the configuration axes of the set axes group by setting the end point and sub point of the absolute position. | Page 1759 Absolute Value Circular Interpolation Control |

## Relative Value Circular Interpolation Control

| Function block symbol               | Processing details                                                                                                                                                                                             | Reference                                               |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| MCv_MoveCircularInterpolateRelative | Performs positioning with 2-axis circular interpolation using the configuration axes of the set axes group by setting the relative position from the current position at start to the end point and sub point. | Page 1776 Relative Value Circular Interpolation Control |

## Cam Operation Start

| Function block symbol | Processing details                                        | Reference                     |
|-----------------------|-----------------------------------------------------------|-------------------------------|
| MC_CamIn              | Starts cam operation according to the specified cam data. | Page 1795 Cam Operation Start |

## Gear Operation Start

| Function block symbol | Processing details                                           | Reference                      |
|-----------------------|--------------------------------------------------------------|--------------------------------|
| MC_GearIn             | Starts gear operation according to the specified gear ratio. | Page 1825 Gear Operation Start |

## Addition/Subtraction Positioning

| Function block symbol | Processing details                                                                                                                           | Reference                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| MC_CombineAxes        | Adds or subtracts the movement amounts of the two specified master axes and performs positioning using said value as the commanded position. | Page 1835 Addition/Subtraction Positioning |

## Backlash Compensation Filter

| Function block symbol          | Processing details                                                                                                         | Reference                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| MCv_BacklashCompensationFilter | Performs filter processing that compensates the backlash amount in the machine system according to the movement direction. | Page 1847 Backlash Compensation Filter |

## Smoothing Filter

| Function block symbol | Processing details                                               | Reference                  |
|-----------------------|------------------------------------------------------------------|----------------------------|
| MCv_SmoothingFilter   | Performs filter processing according to the specified frequency. | Page 1861 Smoothing Filter |

## Moving Direction Restriction Filter

| Function block symbol | Processing details                                                               | Reference                                     |
|-----------------------|----------------------------------------------------------------------------------|-----------------------------------------------|
| MCv_DirectionFilter   | Performs filter processing to restrict traveling for the set movement direction. | Page 1871 Moving Direction Restriction Filter |

## Speed Limit Filter

| Function block symbol | Processing details                                                             | Reference                    |
|-----------------------|--------------------------------------------------------------------------------|------------------------------|
| MCv_SpeedLimitFilter  | Performs filter processing to restrict to the velocity of the set limit value. | Page 1880 Speed Limit Filter |

## Axis control start wait

| Function block symbol | Processing details                                                                                                                       | Reference                         |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| MCv_MoveWait          | Immediately performs the operation of the multiple-started motion FB for the specified axis by inputting an execution permission signal. | Page 1889 Axis Control Start Wait |

## Axes group control start wait

| Function block symbol | Processing details                                                                                                                             | Reference                               |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| MCv_GroupMoveWait     | Immediately performs the operation of the multiple-started motion FB for the specified axes group by inputting an execution permission signal. | Page 1896 Axes Group Control Start Wait |

## Advanced Synchronous Control

| Function block symbol | Processing details                                                                               | Reference                              |
|-----------------------|--------------------------------------------------------------------------------------------------|----------------------------------------|
| MCv_AdvancedSync      | Starts synchronization control according to the specified advanced synchronous control settings. | Page 1903 Advanced Synchronous Control |

## Multiple Axes Positioning Data Operation

| M+MXF-TSN_SLMP_DeviceWrite_IP | Writes device data to the SLMP-compatible device specified by an IP address.  | Page 2020 M+MXF-TSN_SLMP_DeviceWrite_IP |

## 10.2 Function Blocks for CC-Link IE TSN

### Remote reset of SLMP frames

| Function block symbol     | Processing details                                                                          | Reference                           |
|---------------------------|---------------------------------------------------------------------------------------------|-------------------------------------|
| M+MXF-TSN_RemoteReset2_IP | Sends the remote RESET of an SLMP request to the target station specified by an IP address. | Page 2027 M+MXF-TSN_RemoteReset2_IP |

## PART 3

# SEQUENCE INSTRUCTIONS/BASIC INSTRUCTIONS

This part consists of the following chapters.

11 SEQUENCE INSTRUCTIONS

---

12 BASIC INSTRUCTIONS

---

# 11 SEQUENCE INSTRUCTIONS

## 11.1 Contact Instructions

### Operation start, series connection, parallel connection

#### LD, LDI, AND, ANI, OR, ORI

- LD: Normally open contact operation start, LDI: Normally closed contact operation start

These instructions output the on/off information of the specified device as the operation result.

- AND: Normally open contact series connection, ANI: Normally closed contact series connection

These instructions perform an AND operation between the on/off information of the specified device and the previous operation result, and output the operation result.

- OR: Single normally open contact parallel connection, ORI: Single normally closed contact parallel connection

These instructions perform an OR operation between the on/off information of the specified device and the previous operation result, and output the operation result.

| Ladder                                                                             | ST            |

## Processing details

### ■LD, LDI

LD is a normally open contact operation start instruction and LDI is a normally closed contact operation start instruction. These instructions read the on/off information<sup>\*1</sup> of the specified bit device, and output it as the operation result.

<sup>\*1</sup> When a bit of a word device is specified, the instruction outputs on or off according to the status (1 or 0) of the specified bit.

### ■AND, ANI

AND is a normally open contact series connection instruction and ANI is a normally closed contact series connection instruction. These instructions read the on/off information<sup>\*1</sup> of the specified bit device, perform an AND operation with the previous operation result, and output the operation result.

<sup>\*1</sup> When a bit of a word device is specified, the instruction outputs on or off according to the status (1 or 0) of the specified bit.

- Note the following when creating or displaying a program using the engineering tool (in ladder edit mode).
  - Write mode: When the AND and ANI instructions are connected in series, a ladder with up to 24 steps can be created.
  - Read mode: When the AND and ANI instructions are connected in series, a ladder with up to 24 steps can be displayed. If there are more than 24 steps, up to 24 steps are displayed.

### ■OR, ORI

- OR is a single normally open contact parallel connection instruction and ORI is a single normally closed contact parallel connection instruction. These instructions read the on/off information<sup>\*1</sup> of the specified bit device, perform an OR operation with the previous operation result, and output the operation result.

<sup>\*1</sup> When a bit of a word device is specified, the instruction outputs on or off according to the status (1 or 0) of the specified bit.

- Note the following when creating or displaying a program using the engineering tool (in ladder edit mode).
  - Write mode: Up to 23 OR and ORI instructions can be connected consecutively.
  - Read mode: Up to 23 OR and ORI instructions connected consecutively can be displayed. A ladder with more than 23 instructions cannot be displayed correctly.

### ■Operation using LD, LDI, AND, ANI, OR, and ORI combined

An example of operation using LD, AND, and OR combined is shown below. The same operation is performed by using LDI, ANI, and ORI instead.

### Point

Specify a bit in a word device in hexadecimal. (For example, specify "D0.0B" for b11 in D0.)

## Operation error

There is no operation error.

# Pulse operation start, pulse series connection, pulse parallel connection

## LDP, LDF, ANDP, ANDF, ORP, ORF

- LDP: Rising edge pulse operation start

This instruction turns on only at the rising edge (off to on) of the specified bit device.

- LDF: Falling edge pulse operation start

This instruction turns on only at the falling edge (on to off) of the specified bit device.

- ANDP: Rising edge pulse series connection, ANDF: Falling edge pulse series connection

These instructions perform an AND operation with the previous operation result.

- ORP: Rising edge pulse parallel connection, ORF: Falling edge pulse parallel connection

These instructions perform an OR operation with the previous operation result.

| Ladder | ST                                                                                                             |

| (s)     | ○                                | ○   | ○                                     | ○          | — | ○           | —  | ○                      | —        | — | —  | ○           |

## Processing details

### ■LDP, LDF

- LDP is a rising edge pulse operation start instruction, and turns on only at the rising edge (off to on) of the specified bit device. When a bit-specified word device is used, this instruction turns on only when the specified bit changes from 0 to 1. In cases where there is an LDP instruction only, it acts identically to instructions for conversion to pulses that are executed during on (□P).

The following figure shows an example when a ladder using the LDP instruction is replaced with a ladder not using the LDP instruction.

- LDF is a falling edge pulse operation start instruction and turns on only at the falling edge (on to off) of the specified bit device. When a bit-specified word device is used, this instruction turns on only when the specified bit changes from 1 to 0.
- If the LDP instruction is used in the program written in ST language or FBD/LD, ENO turns on at the rising edge (off to on) of the specified bit device (s).
- If the LDF instruction is used in the program written in ST language or FBD/LD, ENO turns on at the falling edge (on to off) of the specified bit device (s).
- If the LDP or LDF instruction is used in the program written in ST language, set EN to be always on.
- If the LDP or LDF instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.

### ■ANDP, ANDF

- ANDP is a rising edge pulse series connection instruction and ANDF is a falling edge pulse series connection instruction. These instructions perform an AND operation with the previous operation result, and output the operation result. The following table lists the on/off information used by the ANDP and ANDF instructions.

| Device specified by ANDP or ANDF |                           | ANDP status | ANDF status |
|----------------------------------|---------------------------|-------------|-------------|
| Bit device                       | Bit-specified word device |             |             |
| Off→On                           | 0→1                       | On          | Off         |
| Off                              | 0                         | Off         | Off         |
| On                               | 1                         | Off         | Off         |
| On→Off                           | 1→0                       | Off         | On          |

- If the ANDP instruction is used in the program written in ST or FBD/LD language, ENO turns on when the result of AND operation between EN and the rising edge of the specified bit device (s) is on. EN will not be an execution condition.
- If the ANDF instruction is used in the program written in ST or FBD/LD language, ENO turns on when the result of AND operation between EN and the falling edge of the specified bit device (s) is on. EN will not be an execution condition.

## ■ORP, ORF

- ORP is a rising edge pulse parallel connection instruction and ORF is a falling edge pulse parallel connection instruction. These instructions perform an OR operation with the previous operation result, and output the operation result. The following table lists the on/off information used by the ORP and ORF instructions.

| Device specified by ORP or ORF |                           | ORP status | ORF status |
|--------------------------------|---------------------------|------------|------------|
| Bit device                     | Bit-specified word device |            |            |
| Off→On                         | 0→1                       | On         | Off        |
| Off                            | 0                         | Off        | Off        |
| On                             | 1                         | Off        | Off        |
| On→Off                         | 1→0                       | Off        | On         |

- If the ORP instruction is used in the program written in ST or FBD/LD language, ENO turns when the result of OR operation between EN and the rising edge of the specified bit device (s) is on. EN will not be an execution condition.
- If the ORF instruction is used in the program written in ST or FBD/LD language, ENO turns when the result of OR operation between EN and the falling edge of the specified bit device (s) is on. EN will not be an execution condition.

## ■Operation using LDP, LDF, ANDP, ANDF, ORP, and ORF combined

An example of operation using LDP, LDF, ANDP, ANDF, ORP, and ORF combined is same as that using LD, AND, and OR.

( Page 206 LD, LDI, AND, ANI, OR, ORI)

### Operation error

There is no operation error.

# Pulse NOT operation start, pulse NOT series connection, pulse NOT parallel connection

## LDPI, LDFI, ANDPI, ANDFI, ORPI, ORFI

- LDPI: Rising edge pulse NOT operation start

This instruction turns on when the specified device is off, on, or at the falling edge (on to off).

- LDFI: Falling edge pulse NOT operation start

This instruction turns on when the specified bit device is at the rising edge (off to on), off, or on.

- ANDPI: Rising edge pulse NOT series connection, ANDFI: Falling edge pulse NOT series connection

These instructions perform an AND operation with the previous operation result.

- ORPI: Rising edge pulse NOT parallel connection, ORFI: Falling edge pulse NOT parallel connection

These instructions perform an OR operation with the previous operation result.

| Ladder                                                                             | ST                                                                                                                   |

## Processing details

### ■LDPI, LDFI

- LDPI is a rising edge pulse NOT operation start instruction, and turns on when the specified device is off, on, or at the falling edge (on to off). When a bit-specified word device is used, this instruction turns on when the specified bit is 0 or 1 or when the bit changes from 1 to 0.
- LDFI is a falling edge pulse NOT operation start instruction, and turns on when the specified bit device is at the rising edge (off to on), off, or on. When a bit-specified word device is used, this instruction turns on when the specified bit is 0 or 1 or when the bit changes from 0 to 1. The following table lists the on/off information used by the LDPI and LDFI instructions.

| Device specified by LDPI or LDFI |                           | LDPI status | LDFI status |
|----------------------------------|---------------------------|-------------|-------------|
| Bit device                       | Bit-specified word device |             |             |
| Off→On                           | 0→1                       | Off         | On          |
| Off                              | 0                         | On          | On          |
| On                               | 1                         | On          | On          |
| On→Off                           | 1→0                       | On          | Off         |

- If the LDPI instruction is used in the program written in ST language or FBD/LD, ENO turns on at the timing except the rising edge (off to on) of the specified bit device (s).
- If the LDFI instruction is used in the program written in ST language or FBD/LD, ENO turns on at the timing except the falling edge (on to off) of the specified bit device (s).
- If the LDPI or LDFI instruction is used in the program written in ST language, set EN to be always on.
- If the LDPI or LDFI instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.

### ■ANDPI, ANDFI

- ANDPI is a rising edge pulse NOT series connection instruction and ANDFI is a falling edge pulse NOT series connection instruction. These instructions perform an AND operation with the previous operation result, and output the operation result. The following table lists the on/off information used by the ANDPI and ANDFI instructions.

| Device specified by ANDPI or ANDFI |                           | ANDPI status | ANDFI status |
|------------------------------------|---------------------------|--------------|--------------|
| Bit device                         | Bit-specified word device |              |              |
| Off→On                             | 0→1                       | Off          | On           |
| Off                                | 0                         | On           | On           |
| On                                 | 1                         | On           | On           |
| On→Off                             | 1→0                       | On           | Off          |

- If the ANDPI instruction is used in the program written in ST or FBD/LD language, ENO turns on when the result of AND operation between EN and the rising edge of the specified bit device (s) is not on. EN will not be an execution condition.
- If the ANDFI instruction is used in the program written in ST or FBD/LD language, ENO turns on when the result of AND operation between EN and the falling edge of the specified bit device (s) is not on. EN will not be an execution condition.

## ■ORPI, ORFI

- ORPI is a rising edge pulse NOT parallel connection instruction and ORFI is a falling edge pulse NOT parallel connection instruction. These instructions perform an OR operation with the previous operation result, and output the operation result. The following table lists the on/off information used by the ORPI and ORFI instructions.

| Device specified by ORPI or ORFI |                           | ORPI status | ORFI status |
|----------------------------------|---------------------------|-------------|-------------|
| Bit device                       | Bit-specified word device |             |             |
| Off→On                           | 0→1                       | Off         | On          |
| Off                              | 0                         | On          | On          |
| On                               | 1                         | On          | On          |
| On→Off                           | 1→0                       | On          | Off         |

- If the ORPI instruction is used in the program written in ST or FBD/LD language, ENO turns when the result of OR operation between EN and the rising edge of the specified bit device (s) is not on. EN will not be an execution condition.
- If the ORFI instruction is used in the program written in ST or FBD/LD language, ENO turns when the result of OR operation between EN and the falling edge of the specified bit device (s) is not on. EN will not be an execution condition.

## ■Operation using LDPI, LDFI, ANDPI, ANDFI, ORPI, and ORFI combined

An example of operation using LDPI, LDFI, ANDPI, ANDFI, ORPI, and ORFI combined is same as that using LD, AND, and OR. (☞ Page 206 LD, LDI, AND, ANI, OR, ORI)

### Operation error

There is no operation error.

# 11.2 Association Instructions

## Ladder block series/parallel connection

### ANB, ORB

- ANB: Ladder block series connection  
This instruction performs an AND operation between block A and block B.
- ORB: Ladder block parallel connection  
This instruction performs an OR operation between block A and block B.

| Ladder                                                                                                      | ST            |
|-------------------------------------------------------------------------------------------------------------|---------------|
| <div> <div> <div>ANB</div> </div> <div> <div>ORB</div> </div> </div> <div> A: A block<br/>B: B block </div> | Not supported |

### FBD/LD

Not supported

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| ANB<br>ORB  | Every scan          |

### Processing details

#### ■ANB

- This instruction performs an AND operation between block A and block B, and outputs the operation result.
- The symbol of the ANB instruction is not a contact but a connection.

#### ■ORB

- This instruction performs an OR operation between block A and block B, and outputs the operation result.
- Ladder blocks, each having two or more contacts, are connected in parallel. Use the OR or ORI instruction for connection of blocks, each having only one contact. The ORB instruction is not required in this case.
- The symbol of the ORB instruction is not a contact but a connection.

### Operation error

There is no operation error.

# Inverting the operation result

## INV

This instruction inverts the operation result up to just before the INV instruction.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | ENO:=INV(EN); |
| FBD/LD                                                                            |               |
|  |               |

## ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| INV         | Every scan          |

## Processing details

- This instruction inverts the operation result up to just before the INV instruction.

| Operation result up to just before the INV instruction | Operation result after execution of the INV instruction |
|--------------------------------------------------------|---------------------------------------------------------|
| Off                                                    | On                                                      |
| On                                                     | Off                                                     |

## Operation error

There is no operation error.

### Point

- The INV instruction operates based on the results of calculation made until the INV instruction is given. Accordingly, use it in the same position as that of the AND (  Page 206 Operation start, series connection, parallel connection). The INV instruction cannot be used at the LD and OR (  Page 206 Operation start, series connection, parallel connection) positions.
- When a ladder block is used, the operation result is inverted within the range of the ladder block. When the INV instruction and the ANB instruction are used together in the same ladder, pay attention to the inversion range.

Broken line part: Inversion range

For details on the ANB instruction, refer to the following.

 Page 214 ANB, ORB

# Converting the operation result into a pulse

## MEP, MEF

- MEP: Converting the operation result into a pulse (rising edge)

This instruction turns on at the rising edge (off to on) of the operation result up to the MEP instruction.

- MEF: Converting the operation result into a pulse (falling edge)

This instruction turns on at the falling edge (on to off) of the operation result up to the MEF instruction.

| Ladder                                                                            | ST                             |
|-----------------------------------------------------------------------------------|--------------------------------|
|  | ENO:=MEP(EN);<br>ENO:=MEF(EN); |
| FBD/LD                                                                            |                                |
|  |                                |

## ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| MEP<br>MEF  | Every scan          |

## Processing details

### ■MEP

- This instruction turns on (continuity state) at the rising edge (off to on) of the operation result up to the MEP instruction. The instruction turns off (non-continuity state) when the operation result is in another state (not rising edge).
- Use of the MEP instruction eases pulse conversion processing when multiple contacts are connected in series.

### ■MEF

- This instruction turns on (continuity state) at the falling edge (on to off) of the operation result up to the MEF instruction. The instruction turns off (non-continuity state) when the operation result is in another state (not falling edge).
- Use of the MEF instruction eases pulse conversion processing when multiple contacts are connected in series.

## Operation error

There is no operation error.

### Point

- The MEP or MEF instruction may not operate correctly if pulse conversion is performed for an index-modified contact in the subroutine program or in the area between the FOR and NEXT instructions. To perform pulse conversion for an index-modified contact in the subroutine program or in the area between the FOR and NEXT instructions, refer to the following.  
 ➞ Page 217 EGP, EGF
- The MEP or MEF instruction operates based on the result of operation performed from the LD instruction immediately before the MEP or MEF instruction until the MEP or MEF instruction is given. Therefore, use them at the same position as that of the AND (➞ Page 206 Operation start, series connection, parallel connection). The MEP or MEF instruction cannot be used at the LD and OR (➞ Page 206 Operation start, series connection, parallel connection) positions.

# Converting the edge relay operation result into a pulse

## EGP, EGF

- EGP: Converting the edge relay operation result into a pulse (rising edge)

This instruction stores the operation result up to the EGP instruction in the edge relay (V). The instruction turns on at the rising edge (off to on) of the operation result.

- EGF: Converting the edge relay operation result into a pulse (falling edge)

This instruction stores the operation result up to the EGF instruction in the edge relay (V). The instruction turns on at the falling edge (on to off) of the operation result.

| Ladder                                                                            | ST                                         |
|-----------------------------------------------------------------------------------|--------------------------------------------|
|  | <pre>ENO:=EGP(EN,d); ENO:=EGF(EN,d);</pre> |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

## Execution condition

| Instruction | Execution condition                                                                 |
|-------------|-------------------------------------------------------------------------------------|
| EGP         |  |
| EGF         |  |

## Setting data

## Description, range, data type

| Operand | Description                                    | Range | Data type | Data type (label) |
|---------|------------------------------------------------|-------|-----------|-------------------|
| (d)     | Edge relay number for storing operation result | —     | Bit       | ANY_BOOL*1        |
| EN      | Execution condition                            | —     | Bit       | BOOL              |
| ENO     | Execution result                               | —     | Bit       | BOOL              |

\*1 Only bit type labels assigned to the device (V) can be used.

## Applicable devices

| Operand | Bit                              |     | Word                                  |            | Z | Double word |    | Indirect specification | Constant |   |    | Others (V) |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|------------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□ |   | LT, LST, LC | LZ |                        | K, H     | E | \$ |            |
| (d)     | —                                | —   | —                                     | —          | — | —           | —  | —                      | —        | — | —  | ○          |

## Processing details

### ■EGP

- This instruction stores the operation result up to the EGP instruction in the edge relay (V).
- The instruction turns on (continuity state) at the rising edge (off to on) of the operation result up to the EGP instruction. The instruction turns off (non-continuity state) when the operation result is in another state (staying on, falling edge (on to off), or staying off).
- The instruction is used to perform pulse conversion for index-modified programs in the subroutine program or in the area between the FOR and NEXT instructions.
- The instruction can be used in the same way as the AND instruction.
- The following figure shows the operation performed when the instruction is used in the subroutine program.

- (1) The device turns on at the rising edge of X40.  
 (2) The device turns off at the falling edge of X40.  
 (3) The device turns on at the rising edge of X41.

### ■EGF

- This instruction stores the operation result up to the EGF instruction in the edge relay (V).
- The instruction turns on (continuity state) at the falling edge (on to off) of the operation result up to the EGF instruction. The instruction turns off (non-continuity state) when the operation result is in another state (staying on, rising edge (off to on), or staying off).
- The instruction is used to perform pulse conversion for index-modified programs in the subroutine program or in the area between the FOR and NEXT instructions.
- The instruction can be used in the same way as the AND instruction.

## Operation error

There is no operation error.

### Point

- The EGP or EGF instruction operates based on the result of operation performed from the LD instruction immediately before the EGP or EGF instruction until the EGP or EGF instruction is given. Therefore, use them at the same position as that of the AND (Page 206 Operation start, series connection, parallel connection). The EGP or EGF instruction cannot be used at the LD and OR (Page 206 Operation start, series connection, parallel connection) positions.
- The instructions cannot be used at the ladder block position shown below.

# 11.3 Output Instructions

## Out (excluding the timer, counter, and annunciator)

### OUT

This instruction outputs the operation result to the specified device.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=OUT(EN,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| OUT         | Every scan          |

### Setting data

### ■Description, range, data type

| Operand | Description                 | Range | Data type | Data type (label) |
|---------|-----------------------------|-------|-----------|-------------------|
| (d)     | On/off target device number | —     | Bit       | ANY_BOOL          |
| EN      | Execution condition         | —     | Bit       | BOOL              |
| ENO     | Execution result            | —     | Bit       | BOOL              |

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others (DY) |
|---------|----------------------------------|-----|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|-------------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |             |
| (d)     | ○*1                              | ○   | ○*2                                   | ○           | — | —           | —  | ○                      | —        | — | —  | ○           |

\*1 When F is used, refer to the following.

☞ Page 231 OUT F

\*2 When T or ST is used, refer to the following.

☞ Page 221 OUT T, OUTH T, OUT ST, OUTH ST

When C is used, refer to the following.

☞ Page 227 OUT C

## Processing details

- This instruction outputs the operation result up to the OUT instruction to the specified device.

| Condition                                | Operation result | Coil/Specified bit |
|------------------------------------------|------------------|--------------------|
| When a bit device is used                | Off              | Off                |
|                                          | On               | On                 |
| When a bit-specified word device is used | Off              | 0                  |
|                                          | On               | 1                  |

- When indirect specification is used, specify the bit as shown below.

(1) The operation result is output to bit 0 of the indirect address stored in D0.

## Operation error

There is no operation error.

# Timer

## OUT T, OUTH T, OUT ST, OUTH ST

- OUT T: Low-speed timer instruction
- OUTH T: High-speed timer instruction
- OUT ST: Low-speed retentive timer instruction
- OUTH ST: High-speed retentive timer instruction

These instructions start time measurement when the operation result up to the OUT instruction is on. When time is up, the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).

| Ladder                                                                                                    | ST                                                              |

| Coil    | —                                | —   | —                                     | —         | — | —           | —  | —                      | —        | — | —  | — | —           |
| Value   | —                                | —   | ○*2                                   | ○         | — | —           | —  | —                      | ○*3      | — | —  | — | —           |

\*1 Only T and ST can be used.

\*2 T, ST, and C cannot be used.

\*3 Only K (decimal constant) can be used.

## Processing details

- These instructions start time measurement, triggered by the coil specified by (d) (in ST language or FBD/LD, displayed as Coil), when the operation result up to the OUT instruction is on. When time is up (current value  $\geq$  set value), the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).
- When the operation result up to the OUT instruction turns off, the contact responds as shown below.

| Type                       | Timer coil | Current value          | Before time is up     |                         | After time is up      |                         |
|----------------------------|------------|------------------------|-----------------------|-------------------------|-----------------------|-------------------------|
|                            |            |                        | Normally open contact | Normally closed contact | Normally open contact | Normally closed contact |
| Low-speed timer            | Off        | 0                      | Non-continuity        | Continuity              | Non-continuity        | Continuity              |
| High-speed timer           |            |                        |                       |                         |                       |                         |
| Low-speed retentive timer  | Off        | Current value retained | Non-continuity        | Continuity              | Continuity            | Non-continuity          |
| High-speed retentive timer |            |                        |                       |                         |                       |                         |

- To clear the current value of the retentive timer and turn off the contact after time is up, use the RST instruction.
- When the timer set value is 0, the time will be up at execution of the OUT instruction.
- The following operations are performed at execution of the OUT instruction.
  - The coil used as a trigger of the OUT T, OUTH T, OUT ST, or OUTH ST instruction turns on or off.
  - The contact used as a trigger of the OUT T, OUTH T, OUT ST, or OUTH ST instruction turns on or off.
  - The current value of the OUT T, OUTH T, OUT ST, or OUTH ST instruction is changed.
- If the OUT T instruction is skipped by using such as the JMP instruction while the OUT T, OUTH T, OUT ST, or OUTH ST instruction is on, the current value is not updated or the contact is not turned on or off.
- If the same OUT T, OUTH T, OUT ST, or OUTH ST instruction is executed two times or more in a single scan, the current value is updated by the number of times the instruction is executed.

### Point

The timer limit value is set in parameter using the engineering tool.

- Low-speed timer/low-speed retentive timer: 1 to 10000ms (in increments of 1ms) (Default: 100ms)
- High-speed timer/high-speed retentive timer: 0.01 to 100.0ms (in increments of 0.01ms) (Default: 10.0ms)

For the counting method, refer to the following.

 User's manual for the controller used

## Precautions

To create a program in which the operation of a timer contact triggers the operation of another timer, program the timers in order from the one that operates last.

When the set value of the timer is shorter than the scan time, if a program is created in order of timer measurements, all timers turn on in the same scan.

- The set value is smaller than the scan time.
- The set value is 1.

### Ex.

When timers T0 to T2 are programmed in order from the one that measures last

- (3) Timer T0 starts measurement when X40 turns on.
- (2) Timer T1 starts measurement from the next scan after the contact of timer T0 turns on.
- (1) Timer T2 starts measurement from the next scan after the contact of timer T1 turns on.

### Ex.

When timers T0 to T2 are programmed in order of measurement

- (1) Timer T0 starts measurement when X40 turns on.
- (2) When the contact of timer T0 turns on, the contacts of timers T1 and T2 also turn on.

## Operation error

There is no operation error.

# Long timer

## OUT LT, OUT LST

- OUT LT: Low-speed long timer instruction
- OUT LST: Low-speed long retentive timer instruction

These instructions start time measurement when the operation result up to the OUT instruction is on. When time is up, the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).

\*1 Only LT and LST can be used.

\*2 T, ST, and C cannot be used.

\*3 Only K (decimal constant) can be used.

## Processing details

- These instructions start time measurement, triggered by the coil specified by (d) (in SD language or FBD/LD, displayed as Coil), when the operation result up to the OUT instruction is on. When time is up (current value  $\geq$  set value), the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).
- When the operation result up to the OUT instruction turns off, the contact responds as shown below.

| Type                 | Timer coil | Current value          | Before time is up     |                         | After time is up      |                         |
|----------------------|------------|------------------------|-----------------------|-------------------------|-----------------------|-------------------------|
|                      |            |                        | Normally open contact | Normally closed contact | Normally open contact | Normally closed contact |
| Long timer           | Off        | 0                      | Non-continuity        | Continuity              | Non-continuity        | Continuity              |
| Long retentive timer | Off        | Current value retained | Non-continuity        | Continuity              | Continuity            | Non-continuity          |

- To clear the current value of the long retentive timer and turn off the contact after time is up, use the RST instruction.
- When the timer set value is 0, the time will be up at execution of the OUT instruction.
- The following operations are performed at execution of the OUT instruction.
  - The coil used as a trigger of the OUT LT or OUT LST instruction turns on or off.
  - The contact used as a trigger of the OUT LT or OUT LST instruction turns on or off.
  - The current value of the OUT LT or OUT LST instruction is changed.
- If the OUT LT instruction is skipped by using such as the JMP instruction while the OUT LT or OUT LST instruction is on, the current value is not updated or the contact is not turned on or off.
- If the same OUT LT or OUT LST instruction is executed two times or more in a single scan, the current value is updated by the number of times the instruction is executed.

### Point

The timer limit value is set in parameter using the engineering tool.

- Long timer/long retentive timer: 0.001 to 1000ms (in increments of 0.001ms) (Default: 0.001ms)

For the counting method, refer to the following.

 User's manual for the controller used

## Precautions

To create a program in which the operation of a long timer contact triggers the operation of another long timer, program the long timers in order from the one that operates first.

When long timers are programmed in order from the one that operates last, the timer measurement error may increase.

When the setting value of the long timer is shorter than the scan time, the operations are as follows.

**Ex.**

When long timers LT0 to LT2 are programmed in order of measurement

- (1) Timer LT0 starts measurement when X40 turns on.
- (2) When the contact of timer LT0 turns on, timer LT1 and then timer LT2 start measurement.

**Ex.**

When timers LT0 to LT2 are programmed in order from the one that measures last

- (3) Timer LT0 starts measurement when X40 turns on.
- (2) Long timer LT1 starts measurement from the next scan after the contact of long timer LT0 turns on.
- (1) Long timer LT2 starts measurement from the next scan after the contact of long timer LT1 turns on.

## Operation error

There is no operation error.

## OUT C

This instruction increments the current counter value (count value) by one when the operation result up to the OUT instruction turns on. When the count value reaches the set value, the normally open contact of the counter turns on (continuity state) and the normally closed contact turns off (non-continuity state).

| Ladder                                                                                                    | ST                                    |
|-----------------------------------------------------------------------------------------------------------|---------------------------------------|

\*1 Only C can be used.

\*2 T, ST, and C cannot be used.

\*3 Only K (decimal constant) can be used.

## Processing details

- This instruction increments the current counter value (count value) in the device specified by (d) (in ST language or FBD/LD, displayed as Coil) by one on the rising edge (off to on) of the operation result up to the OUT instruction. When the count value reaches the set value (current value  $\geq$  set value), the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).
- When the set value is 0, the same processing is performed as when it is set to the above.
- Counting is disabled while the operation result remains on. (Count input does not need to be converted into pulses.)
- After counting-up, the count value and contact status remain unchanged until the RST instruction is executed.

## Operation error

There is no operation error.

# Long counter

## OUT LC

This instruction increments the current long counter value (count value) by one on the rising edge (off to on) of the operation result up to the OUT instruction. When the count value reaches the set value, the normally open contact of the long counter turns on (continuity state) and the normally closed contact turns off (non-continuity state).

| Ladder                                                                                                                                        | ST                                    |
|-----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
|  <p>Value: Set value</p>                                     | <pre>ENO:=OUT_C(EN,Coil,Value);</pre> |

| (d)     | —                                | —    | —                                     | —           | — | ○ <sup>*1</sup> | —  | —                      | —               | — | —  | —      |
| Coil    |                                  |      |                                       |             |   |                 |    |                        |                 |   |    |        |
| Value   | —                                | —    | ○ <sup>*2</sup>                       | ○           | — | —               | —  | —                      | ○ <sup>*3</sup> | — | —  | —      |

\*1 Only LC can be used.

\*2 T, ST, and C cannot be used.

\*3 Only K (decimal constant) can be used.

## Processing details

- This instruction increments the current long counter value (count value) in the device specified by (d) (in ST language or FBD/LD, displayed as Coil) by one on the rising edge (off to on) of the operation result up to the OUT instruction. When the count value reaches the set value (current value  $\geq$  set value), the normally open contact turns on (continuity state) and the normally closed contact turns off (non-continuity state).
- When the set value is 0, the same processing is performed as when it is set to the above.
- Counting is disabled while the operation result remains on. (Count input does not need to be converted into pulses.)
- After counting-up, the count value and contact status remain unchanged until the RST instruction is executed.

## Operation error

There is no operation error.

# Annunciator

## OUT F

This instruction outputs the operation result up to the OUT F instruction to the specified annunciator.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=OUT(EN,d); |

## FBD/LD

(□ is to be replaced by OUT.)

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| OUT F       | Every scan          |

## Setting data

## Description, range, data type

| Operand | Description               | Range | Data type | Data type (label)      |
|---------|---------------------------|-------|-----------|------------------------|
| (d)     | Target annunciator number | —     | Bit       | ANY_BOOL <sup>*1</sup> |
| EN      | Execution condition       | —     | Bit       | BOOL                   |
| ENO     | Execution result          | —     | Bit       | BOOL                   |

<sup>\*1</sup> Only labels assigned to the annunciator can be used.

## Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□\□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (d)     | ○ <sup>*1</sup>                  | —    | —                                     | —           | — | —           | —  | —                      | —        | — | —  | —      |

<sup>\*1</sup> Only F can be used.

## Processing details

- This instruction outputs the operation result up to the OUT F instruction to the specified annunciator.
- When the annunciator (F) is turned on by this instruction, the following are performed.
  - The USER LED of the controller turns on.
  - The annunciator number (F number) to be turned on is stored in the special register (SD64 to SD79).
  - The value in SD63 is incremented by one.
- If the value in SD63 is 16 (meaning 16 annunciators are already on), the annunciator number will not be stored in the special register (SD64 to SD79) even when a new annunciator turns on.
- When the annunciator (F) is turned off by this instruction, the following are performed.
  - The coil turns off, but the USER LED status and the data in SD63 to SD79 remain unchanged.
  - To turn off the USER LED or delete the annunciator number that has been turned off by this instruction from SD63 to SD79, use the RST F instruction.

## Operation error

There is no operation error.

## Setting devices (excluding annunciator)

### SET

This instruction turns on the specified bit.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=SET(EN,d); |

| FBD/LD                                                                            |

\*1 When F is used, refer to the following.

 Page 236 SET F

## Processing details

- This instruction changes the device status as follows when the execution command turns on.

| Device                    | Status                        |
|---------------------------|-------------------------------|
| Bit device                | Turns on the coil or contact. |
| Bit-specified word device | Sets the specified bit to 1.  |

- The device that has been turned on remains on even after the execution command turns off. The device that has been turned on can be turned off by using the RST instruction.

- When the execution command is off, the device status does not change.

## Operation error

There is no operation error.

### Point

When X is used, specify a device number that is not used in actual input. If the number that is used in actual input is specified, the data of actual input is written over the input device (X) specified by the SET instruction.

## Resetting devices (excluding annunciator)

### RST

This instruction turns off the specified device. For the timer and counter, the instruction clears the current value to 0 and turns off the contact or coil.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=RST(EN,d); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Execution condition

\*1 Only F can be used.

## Processing details

- This instruction turns on the annunciator specified by (d) when the execution command turns on.
- When the annunciator (F) is turned on, the following are performed.
  - The USER LED turns on.
  - The annunciator number (F number) turned on is stored in the special register (SD64 to SD79).
  - The value in SD63 is incremented by one.
- If the value in SD63 is 16 (meaning 16 annunciators are already on), the annunciator number will not be stored in the special register (SD64 to SD79) even when a new annunciator turns on.

(1) The data remain the same.

## Operation error

There is no operation error.

# Resetting annunciator

## RST F

This instruction turns off the specified annunciator.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|

| <br>(□ is to be replaced by RST.) |

### Execution condition

| Instruction | Execution condition                                                               |
|-------------|-----------------------------------------------------------------------------------|
| RST F       |  |

### Setting data

### Description, range, data type

| Operand | Description                                | Range | Data type         | Data type (label)      |
|---------|--------------------------------------------|-------|-------------------|------------------------|
| (d)     | Reset target annunciator number (F number) | —     | Bit <sup>*1</sup> | ANY_BOOL <sup>*1</sup> |
| EN      | Execution condition                        | —     | Bit               | BOOL                   |
| ENO     | Execution result                           | —     | Bit               | BOOL                   |

<sup>\*1</sup> If the program is written in ST language or FBD/LD, the data type will be ANY\_ELEMENTARY.

### Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□\□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (d)     | ○ <sup>*1</sup>                  | —    | —                                     | —           | — | —           | —  | —                      | —        | — | —  | —      |

<sup>\*1</sup> Only F can be used.

## Processing details

- This instruction turns off the annunciator specified by (d) when the execution command turns on.
- The annunciator number (F number) turned off is deleted from the special register (SD64 to SD79), and the value in SD63 is decremented by one.
- If the value in SD63 is 16, the corresponding annunciator number is deleted from SD64 to SD79 by the RST instruction. If an annunciator with a number not registered in SD64 to SD79 has been turned on, the number is newly registered. If all annunciator numbers in SD64 to SD79 are reset (turned off), the USER LED of the controller turns off.

### Ex.

When the value in SD63 is 16 and there is an annunciator number that is not registered

(1) Reset F90.

(2) The F number in SD66 is shifted to this area.

(3) New F number is stored.

## Operation error

There is no operation error.

# Rising edge output

## PLS

This instruction turns on the specified device for one scan on the rising edge (off to on) of the execution command.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=PLS(EN,d); |

## Processing details

- This instruction turns on the specified device on the rising edge (off to on) of the execution command. When the execution command is in another state (staying on, falling edge (on to off), or staying off), the instruction turns off the specified device. If only one PLS instruction in the device specified by (d) is executed in a single scan, the specified device turns on for one scan. For the operation to be performed if more than one PLS instruction is executed during one scan, refer to the following.

Page 53 Operations arising when the OUT, SET/RST, and PLS/PLF instructions of the same device are used

Sc: 1 scan

- Once after execution of the PLS instruction, even if the switch of the controller is moved to the STOP position and then the RUN position again, the PLS instruction is not executed.

(1) M0 turns on for one scan.

(2) Controller operation stop time

(3) Change the RUN/STOP/RESET switch of the controller from RUN→STOP.

(4) Change the RUN/STOP/RESET switch of the controller from STOP→RUN.

- If the latch relay (L) is specified as the execution command and the system is powered on while the latch relay is on, the execution command turns on in the first scan, triggering execution of the PLS instruction and turning on the specified device. The device that has been turned on in the first scan after power-on can be turned off by the next PLS instruction.
- The PLS instruction performs OFF processing at the execution of the next instruction after the instruction execution.

### Point

- Note that if the PLS instruction is jumped by using the CJ instruction or the executed subroutine program is not called by using the CALL(P) instruction, the device specified by (d) may be on for more than one scan.

## Operation error

There is no operation error.

# Falling edge output

## PLF

This instruction turns on the specified device for one scan on the falling edge (on to off) of the execution command.

| Ladder                                                                            | ST              |
|-----------------------------------------------------------------------------------|-----------------|
|  | ENO:=PLF(EN,d); |

## Processing details

- This instruction turns on the specified device on the falling edge (on to off) of the execution command. When the execution command is in another state (staying off, rising edge (off to on), or staying on), the instruction turns off the specified device. If only one PLF instruction in the device specified by (d) is executed during one scan, the specified device turns on for one scan. For the operation to be performed if more than one PLF instruction is executed during one scan, refer to the following.

☞ Page 53 Operations arising when the OUT, SET/RST, and PLS/PLF instructions of the same device are used

Sc: 1 scan

- Once after execution of the PLF instruction, even if the switch of the controller is moved to the STOP position and then the RUN position again, the PLF instruction is not executed.
- The PLF instruction performs OFF processing at the execution of the next instruction after the instruction execution.

### Point

Note that if the PLF instruction is jumped by using the CJ instruction or the executed subroutine program is not called by using the CALL(P) instruction, the device specified by (d) may be on for more than one scan.

## Operation error

There is no operation error.

# Inverting the bit device output

## FF

This instruction inverts the status of the specified device.

| Ladder                                                                            | ST             |
|-----------------------------------------------------------------------------------|----------------|
|  | ENO:=FF(EN,d); |

## Processing details

- These instructions convert the direct access output (DY) specified by (d) into pulse output. If DY0 is specified by (d), the program operates in the same way as the one that uses the SET and RST instructions.

The following figure shows an example when a ladder using the DELTA instruction is replaced with a ladder using the SET/RST instructions.

The following figure shows the operation of the instruction.

## Precautions

The DELTA(P) instruction is used as an execution command (rising edge execution) for intelligent function modules. The instruction cannot be used as an actual output command for output modules.

## Operation error

There is no operation error.

### Point

The DELTA(P) instruction is used to set a preset value of the high-speed counter module.

# 11.4 Shift Instructions

## Shifting bit devices

### SFT(P)

These instructions shift the on/off state of the device area just before the one specified to the specified device area, and turn off the shift source device.

| Ladder                                                                            | ST                                          |
|-----------------------------------------------------------------------------------|---------------------------------------------|
|  | <pre>ENO:=SFT(EN,d); ENO:=SFTP(EN,d);</pre> |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### ■Execution condition

## Processing details

### ■Bit device

These instructions shift the on/off state of the device area just before the one specified by (d) to the device area specified by (d). After the data is shifted, the data of the shift source device area is turned off.

#### Point

When the SFTP(P) instruction is used consecutively, program devices in descending order of the device numbers.

#### Ex.

The following figure shows an example when the SFTP instruction shifts the device from M10 to M11.

- (1) Initial state
- (2) After the 1st shift input
- (3) After the 2nd shift input
- (5) Shift range

### ■Bit-specified word device

These instructions shift the 1/0 state of the bit just before the one specified by (d) to the bit specified by (d). After the data is shifted, the data of the shift source bit is set to 0.

#### Ex.

The SFTP(P) instruction that specifies D0.5 (b5 in D0) is executed, it shifts the 1/0 state of b4 in D0 to b5, and sets b4 to 0.

- (1) Before shifting the bit
- (2) After shifting the bit

## Operation error

There is no operation error.

# 11.5 Master Control Instructions

11

## Setting/resetting a master control

### MC, MCR

- MC: This instruction starts a master control.
- MCR: This instruction ends a master control.

| Ladder                           | ST                                          |
|----------------------------------|---------------------------------------------|
| <p>(1) Master control ladder</p> | <pre>ENO:=MC(EN,N,d); ENO:=MCR(EN,N);</pre> |

| FBD/LD    |            |
|-----------|------------|
| <p>MC</p> | <p>MCR</p> |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| MC<br>MCR   | Every scan          |

### Setting data

### Description, range, data type

| Operand | Description                          | Range     | Data type   | Data type (label)     |
|---------|--------------------------------------|-----------|-------------|-----------------------|
| (N)     | Nesting                              | N0 to N14 | Device name | ANY16_S <sup>*1</sup> |
| (d)     | Number of the device to be turned on | —         | Bit         | ANY_BOOL              |
| EN      | Execution condition                  | —         | Bit         | BOOL                  |
| ENO     | Execution result                     | —         | Bit         | BOOL                  |

\*1 Only labels assigned to the device (N) or to which constants are assigned can be used.

### Applicable devices

| (d)     | ○                                | ○   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      | ○  |

## Processing details

These instructions are used to create an efficient ladder switching program by opening and closing the common rails of the ladder.

The following is the program example using the master control instructions.

(Left: Display on the engineering tool, Right: Actual operation)

(1) Executed only when X40 is on.

### MC

- If the execution command of the MC instruction is on when a master control starts, the operation result between the MC and MCR instructions will be the one as programmed. If the execution command is off, the operation result between the MC and MCR instructions will be as follows.

| Device                                                                                                                                                 | Status                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| High-speed timer<br>Low-speed timer                                                                                                                    | The count value is set to 0, and both the coil and contact are turned off.                |
| High-speed retentive timer<br>Low-speed retentive timer<br>Counter                                                                                     | The coil is turned off, but both the count value and contact maintain the current status. |
| Device used by the OUT instruction                                                                                                                     | Forcibly turned off.                                                                      |
| Device used by the SET and RST instructions<br>Device used by the SFT(P) instruction<br>Device used by basic instructions and application instructions | Maintains the current status.                                                             |

- Even if the MC instruction is off, the instructions between the MC and MCR instructions are executed and therefore the scan time is not shortened.

### Point

- When a ladder performing a master control includes an instruction which does not require a contact instruction (such as the FOR to NEXT instruction), the controller executes the instruction regardless of the execution command of the MC instruction.
- To create an easy-to-understand program, use the MC and MCR instructions within a single program block.
- The MC instruction can use the same nesting (N) number as many times as needed by specifying different devices in (d).
- When the MC instruction is on, the coil of the device specified by (d) turns on. Using the same device for the OUT instruction causes double coils. Do not use the device specified by (d) in other instructions.

## ■MCR

- This instruction is a master control reset instruction which indicates the end of the master control area.
- Do not place any contact instruction before the MCR instruction.
- Use the MC and MCR instructions with the same nesting number as a set. Note that if the MCR instructions are nested in one place, all master controls can be terminated by specifying the lowest nesting (N) number. (Refer to "Precautions".)

### Operation error

There is no operation error.

#### Point

The master control instructions can be nested. Individual master control areas are distinguished by nesting (N) numbers. Nesting can be set from N0 to N14.

Using the nesting structure enables the creation of a ladder which can sequentially constrain the program execution conditions.

The following figure shows a ladder program example using the nesting structure.

(Left: Display on the engineering tool, Right: Actual operation)

- (1) Executed when A is on.
- (2) Executed when A and B are on.
- (3) Executed when A, B, and C are on.
- (4) Executed regardless of the status of A, B, and C

## Precautions

- Up to 15 nests (N0 to N14) are allowed. When nesting is performed, the MC instruction should use nesting (N) numbers in order from lower numbers and the MCR instruction should use them in order from higher numbers.
- If the MCR instructions are nested in one place, all master controls can be terminated by specifying the lowest nesting (N) number.

# 11.6 Termination Instructions

11

## Ending the main routine program

### FEND

This instruction is used to separate the main routine program from subroutine programs and interrupt programs in a program file.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | Not supported |

### FBD/LD

Not supported

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| FEND        | Every scan          |

### Processing details

- This instruction is used to divide sequence program operations by using a program branch instruction such as the CJ instruction or to separate the main routine program from subroutine programs and interrupt programs specified by the interrupt pointer (I).
- When the instruction is executed, the controller terminates the running program.
- Sequence programs following the FEND instruction can be displayed on the engineering tool (ladder mode).

When the CJ instruction is used

When there are subroutine and interrupt programs

A: Main routine program

B: Subroutine program

C: Interrupt program

(1) Operation performed when the CJ instruction is not executed

(2) Jump caused by the CJ instruction

(3) Operation performed when the CJ instruction is executed

### Operation error

| Error code (SD0) | Description                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 3341H            | After execution of the CALL(P), FCALL(P), ECALL(P), or EFCALL(P) instruction, the FEND instruction is executed before the RET instruction. |
| 3351H            | Within the interrupt program specified by the interrupt pointer (I), the FEND instruction is executed before the IRET instruction.         |

# Ending the sequence program

## END

This instruction indicates the end of a program.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | Not supported |
| FBD/LD                                                                            |               |
| Not supported                                                                     |               |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| END         | Every scan          |

### Processing details

- This instruction indicates the end of a program including a main routine program, subroutine programs, and interrupt programs.
- When the instruction is executed, the controller terminates the running program.

- If END processing is required in the middle of a program, use the FEND instruction.
- If the program is created using the engineering tool (in ladder edit mode), the END instruction is automatically input and cannot be edited.
- The following figure shows how to use the termination instructions when a main routine program, subroutine program, and interrupt program exist.

- A: Main routine program  
B: Subroutine program  
C: Interrupt program  
D: Main sequence program area  
(1) The FEND instruction is required.  
(2) The END instruction is required.

When a program is divided into multiple program blocks, the END instruction indicates the end of a program block.

The END instruction within the program registered at the end of the program setting performs END processing.

## Operation error

| Error code (SD0) | Description                                                                                                                               |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 3341H            | After execution of the CALL(P), FCALL(P), ECALL(P), or EFCALL(P) instruction, the END instruction is executed before the RET instruction. |
| 3351H            | Within the interrupt program specified by the interrupt pointer (I), the END instruction is executed before the IRET instruction.         |

# 11.7 Stop Instruction

## Stopping the sequence program

### STOP

Stops the operation of the controller. (The operation of this instruction is the same as setting the switch of the controller to the STOP position.)

| Ladder                                                                            | ST             |
|-----------------------------------------------------------------------------------|----------------|
|  | ENO:=STOP(EN); |

| FBD/LD                                                                            |
|-----------------------------------------------------------------------------------|
|  |

### Execution condition

| Instruction | Execution condition                                                               |
|-------------|-----------------------------------------------------------------------------------|
| STOP        |  |

### Processing details

- This instruction resets the output (Y) and stops the operation of the controller when the execution command turns on. (The operation of this instruction is the same as setting the switch of the controller to the STOP position.)
- To restart the operation of the controller after execution of the STOP instruction, set the switch back to STOP, and then set it to RUN again.

### Operation error

| Error code (SD0) | Description                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 3341H            | After execution of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), or XCALL instruction, the STOP instruction is executed before the RET instruction. |
| 3351H            | Within the interrupt program specified by the interrupt pointer (I), the STOP instruction is executed before the IRET instruction.                |
| 3353H            | The STOP instruction is executed within a fixed scan execution type program.                                                                      |
| 3354H            | The STOP instruction is executed within an event execution type program.                                                                          |

# 11.8 No Operation Instruction

## No operation (NOPLF)

### NOPLF

This instruction is a no-operation instruction and has no impact on the previous operations.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | Not supported |

| FBD/LD        |
|---------------|
| Not supported |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| NOPLF       | Every scan          |

### Processing details

This instruction is a no-operation instruction and has no impact on the previous operations.

### Operation error

There is no operation error.

# 12 BASIC INSTRUCTIONS

## 12.1 Comparison Operation Instructions

### Comparing 16-bit binary data

#### LD□(\_U), AND□(\_U), OR□(\_U)

These instructions compare the two sets of 16-bit binary data specified. (Devices are used as normally open contacts.)

| Ladder                                                                                                                                                                                                  | ST                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  <p>(□ is to be replaced by any of the following: =( _U), &lt;&gt;(_U), &gt;(_U), &lt;=(_U), &lt;(_U), &gt;=(_U).)</p> | <div>ENO:=LD_□(EN,s1,s2);</div> <div>ENO:=AND_□(EN,s1,s2);</div> <div>ENO:=OR_□(EN,s1,s2);</div> <div>ENO:=LD_□_U(EN,s1,s2);</div> <div>ENO:=AND_□_U(EN,s1,s2);</div> <div>ENO:=OR_□_U(EN,s1,s2);</div> <div>(□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)*1</div> |

#### FBD/LD

(□ is to be replaced by combination of any of the following: LD\_, AND\_, OR\_ and EQ(\_U), NE(\_U), GT(\_U), LE(\_U), LT(\_U), GE(\_U).)\*1

\*1 EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

#### ■Execution condition

| Instruction                | Execution condition |
|----------------------------|---------------------|
| LD□(_U), AND□(_U), OR□(_U) | Every scan          |

## Setting data

### ■Description, range, data type

| Operand | Description          | Range           | Data type              | Data type (label) |
|---------|----------------------|-----------------|------------------------|-------------------|
| (s1)    | LD□, AND□, OR□       | -32768 to 32767 | 16-bit signed binary   | ANY16_S           |
|         | LD□_U, AND□_U, OR□_U | 0 to 65535      | 16-bit unsigned binary | ANY16_U           |
| (s2)    | LD□, AND□, OR□       | -32768 to 32767 | 16-bit signed binary   | ANY16_S           |
|         | LD□_U, AND□_U, OR□_U | 0 to 65535      | 16-bit unsigned binary | ANY16_U           |
| EN      | Execution condition  | —               | Bit                    | BOOL              |
| ENO     | Execution result     | —               | Bit                    | BOOL              |

### ■Applicable devices

| Operand | Bit                              |      | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□\□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |

| (s2)    | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions perform a comparison operation between the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2). (Devices are used as normally open contacts.)
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result                             |
|-------------------------------------|-----------|------------------------------------|
| =(_U), EQ(_U)                       | (s1)=(s2) | Continuity state (ENO is on.)      |
| <>(_U), NE(_U)                      | (s1)≠(s2) |                                    |
| >(_U), GT(_U)                       | (s1)>(s2) |                                    |
| <=(_U), LE(_U)                      | (s1)≤(s2) |                                    |
| <(_U), LT(_U)                       | (s1)<(s2) |                                    |
| >=(_U), GE(_U)                      | (s1)≥(s2) | Non-continuity state (ENO is off.) |
| =(_U), EQ(_U)                       | (s1)≠(s2) |                                    |
| <>(_U), NE(_U)                      | (s1)=(s2) |                                    |
| >(_U), GT(_U)                       | (s1)≤(s2) |                                    |
| <=(_U), LE(_U)                      | (s1)>(s2) |                                    |
| <(_U), LT(_U)                       | (s1)≥(s2) |                                    |
| >=(_U), GE(_U)                      | (s1)<(s2) |                                    |

- When hexadecimal constants are used for (s1) and (s2) and the numerical value (8 to F) whose most significant bit (b15) is 1 is specified as a constant, the value is considered as a negative binary value in comparison operation.
- If the LD□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the OR□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.

## Operation error

There is no operation error.

# Comparing 32-bit binary data

## LDD□(\_U), ANDDD□(\_U), ORD□(\_U)

These instructions compare the two sets of 32-bit binary data specified. (Devices are used as normally open contacts.)

| Ladder                                                                                                                                                                                                       | ST                                                                             |                                                                                 |

## Processing details

- These instructions perform a comparison operation between the 32-bit binary data in the device specified by (s1) and the 32-bit binary data in the device specified by (s2). (Devices are used as normally open contacts.)
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result                             |
|-------------------------------------|-----------|------------------------------------|
| D=(_U), EQ(_U)                      | (s1)=(s2) | Continuity state (ENO is on.)      |
| D<>(_U), NE(_U)                     | (s1)≠(s2) |                                    |
| D>(_U), GT(_U)                      | (s1)>(s2) |                                    |
| D<=(_U), LE(_U)                     | (s1)≤(s2) |                                    |
| D<(_U), LT(_U)                      | (s1)<(s2) |                                    |
| D>=(_U), GE(_U)                     | (s1)≥(s2) |                                    |
| D=(_U), EQ(_U)                      | (s1)≠(s2) | Non-continuity state (ENO is off.) |
| D<>(_U), NE(_U)                     | (s1)=(s2) |                                    |
| D>(_U), GT(_U)                      | (s1)≤(s2) |                                    |
| D<=(_U), LE(_U)                     | (s1)>(s2) |                                    |
| D<(_U), LT(_U)                      | (s1)≥(s2) |                                    |
| D>=(_U), GE(_U)                     | (s1)<(s2) |                                    |

- When hexadecimal constants are specified for (s1) and (s2) and the numerical value (8 to F) whose most significant bit (b31) is 1 is specified as a constant, the value is considered as a negative binary value in comparison operation.
- To specify the compare target data, use an instruction which handles 32-bit data, such as the DMOV(P) instruction. If an instruction which handles 16-bit data, such as the MOV(P) instruction, is used, comparison cannot be performed normally.
- If the LDD□ instruction is used in the program written in FBD/LD, use a left rail or a variable/constant which is always on for EN.
- If the ORD□ instruction is used in the program written in FBD/LD and EN is set to TRUE, ENO turns on. EN will not be an execution condition.

## Operation error

There is no operation error.

# Comparing 16-bit binary block data

## BKCMPP(P)(U)

These instructions compare the two sets of 16-bit binary block data specified.

| Ladder                                                                                                                                                   | ST                                                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>(□ is replaced by any of the following: BKCMP=(P)(U), BKCMP&lt;&gt;(P)(U), BKCMP&gt;(P)(U), BKCMP&lt;=(P)(U), BKCMP&lt;(P)(U), BKCMP&gt;=(P)(U).)</p> | <div>ENO:=BKCMP_□(EN,s1,s2,n,d);</div> <div>ENO:=BKCMP_□P(EN,s1,s2,n,d);</div> <div>ENO:=BKCMP_□_U(EN,s1,s2,n,d);</div> <div>(□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)<sup>*1</sup></div> |

## Processing details

- These instructions compare the (n) points of 16-bit binary data from the device specified by (s1) with the (n) points of 16-bit binary data from the device specified by (s2), and stores the operation result in the device specified by (d) and later.
- If the comparison condition is satisfied, the relevant device specified by (d) turns on; otherwise, the device turns off.

- Specify data in units of 16 bits.
- A constant can be specified for (s1).

- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result  |
|-------------------------------------|-----------|---------|
| BKCOMP=(P)(_U), BKCOMP_EQ(P)(_U)    | (s1)=(s2) | On (1)  |
| BKCOMP<>(P)(_U), BKCOMP_NE(P)(_U)   | (s1)≠(s2) |         |
| BKCOMP>(P)(_U), BKCOMP_GT(P)(_U)    | (s1)>(s2) |         |
| BKCOMP<=(P)(_U), BKCOMP_LE(P)(_U)   | (s1)≤(s2) |         |
| BKCOMP<(P)(_U), BKCOMP_LT(P)(_U)    | (s1)<(s2) |         |
| BKCOMP>=(P)(_U), BKCOMP_GE(P)(_U)   | (s1)≥(s2) |         |
| BKCOMP=(P)(_U), BKCOMP_EQ(P)(_U)    | (s1)≠(s2) | Off (0) |
| BKCOMP<>(P)(_U), BKCOMP_NE(P)(_U)   | (s1)=(s2) |         |
| BKCOMP>(P)(_U), BKCOMP_GT(P)(_U)    | (s1)≤(s2) |         |
| BKCOMP<=(P)(_U), BKCOMP_LE(P)(_U)   | (s1)>(s2) |         |
| BKCOMP<(P)(_U), BKCOMP_LT(P)(_U)    | (s1)≥(s2) |         |
| BKCOMP>=(P)(_U), BKCOMP_GE(P)(_U)   | (s1)<(s2) |         |

- When the comparison operation results stored in (n) points from the device specified by (d) are all on (1), SM704 turns on.

## Operation error

| Error code (SD0) | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| 2821H            | The device ranges starting from the ones specified by (s1) and (d) are overlapping. |
|                  | The device ranges starting from the ones specified by (s2) and (d) are overlapping. |

### Point

When bits of a word device are specified, the bits other than the specified ones for storing the operation result do not change as shown below.

- Number of data points to be compared (n): K5
- Start number of the device for storing the comparison operation result (d): D10.5

# Comparing 32-bit binary block data

12

## DBKCMPP(P)(U)

These instructions compare the two sets of 32-bit binary block data specified.

| Ladder                                                                                                                                                              | ST                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>(□ is replaced by any of the following: DBKCMPP(P)(U), DBKCMPP&lt;&gt;(P)(U), DBKCMPP&gt;(P)(U), DBKCMPP&lt;=(P)(U), DBKCMPP&lt;(P)(U), DBKCMPP&gt;=(P)(U).)</p> | <pre> ENO:=DBKCMPP_□(EN,s1,s2,n,d); ENO:=DBKCMPP_□P(EN,s1,s2,n,d); ; ENO:=DBKCMPP_□P_U(EN,s1,s2,n,d); </pre> <p>(□ is replaced by any of the following: EQ, NE, GT, LE, LT, GE.)*1</p> |

## FBD/LD

(□ is to be replaced by combination of any of the following: DBKCMPP\_ and EQ(P)(U), NE(P)(U), GT(P)(U), LE(P)(U), LT(P)(U), GE(P)(U).)\*1

\*1 EQ indicates =, NE indicates <>, GT indicates >, LE indicates <=, LT indicates <, and GE indicates >=.

## Execution condition

| (n)     | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions compare the (n) points of 32-bit binary data from the device specified by (s1) with the (n) points of 32-bit binary data from the device specified by (s2), and stores the operation result in the device specified by (d) and later.
- If the comparison condition is satisfied, the relevant device specified by (d) turns on; otherwise, the device turns off.

- Comparison operation is performed in units of 32 bits.
- A constant can be specified for (s1).

- Specify (d) outside the device ranges for (n) points from the device specified by (s1) and those from the device specified by (s2).
- The following table lists the comparison operation results of each instruction.

| Instruction symbol (ladder, FBD/LD) | Condition | Result  |
|-------------------------------------|-----------|---------|
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)=(s2) | On (1)  |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)≠(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)>(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)≤(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)<(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)≥(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)≠(s2) | Off (0) |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)=(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)≤(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)>(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)≥(s2) |         |
| DBKCMPEQ(P)(_U), DBKCMPEQ(P)(_U)    | (s1)<(s2) |         |

- When the comparison operation results stored in (n) points from the device specified by (d) are all on (1), SM704 turns on.
- If (n) is 0, no processing is performed.

| Error code (SD0) | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| 2821H            | The device ranges starting from the ones specified by (s1) and (d) are overlapping. |
|                  | The device ranges starting from the ones specified by (s2) and (d) are overlapping. |

## Point

When bits of a word device are specified, the bits other than the specified ones for storing the operation result do not change as shown below.

- Number of data points to be compared (n): K5
- Start number of the device for storing the comparison operation result (d): D10.5

# 12.2 Arithmetic Operation Instructions

## Adding 16-bit binary data

### +(P)(\_U) [when two operands are set]

These instructions add the two sets of 16-bit binary data specified.

| Ladder                                                                            | ST                                                                                                                                                    |

## Processing details

- These instructions subtract the 16-bit binary data in the device specified by (s) from the 16-bit binary data in the device specified by (d), and store the operation result in the device specified by (d).

- If an underflow occurs in the result, the borrow bit is ignored. In this case, SM700 does not turn on.

[-(P) instruction]

[-(P)\_U instruction]

## Operation error

There is no operation error.

## -(P)(\_U) [when three operands are set]

These instructions perform subtraction between the two sets of 16-bit binary data specified.

## Processing details

- These instructions subtract the 32-bit binary data in the device specified by (s) from the 32-bit binary data in the device specified by (d) and, and store the operation result in the device specified by (d).

- If an underflow occurs in the result, the carry bit is ignored. In this case, SM700 does not turn on.

[D-(P) instruction]

[D-(P)\_U instruction]

## Operation error

There is no operation error.

## D-(P)(U) [when three operands are set]

These instructions perform subtraction between the two sets of 32-bit binary data specified.

## Processing details

- These instructions divide the 16-bit binary data in the device specified by (s1) by the 16-bit binary data in the device specified by (s2), and store the operation result in the device specified by (d).

(d): Quotient

(d)+1: Remainder

- As the operation result, the quotient and remainder are stored in 32 bits. When a bit device is specified, the number of digit-specified bits is used to store the quotient and remainder.
- Quotient...Stored in lower 16 bits.
- Remainder...Stored in upper 16 bits.

## Operation error

| Error code (SD0) | Description                                               |
|------------------|-----------------------------------------------------------|
| 3280H            | The value (divisor) in the device specified by (s2) is 0. |

# Multiplying 32-bit binary data

## D\*(P)(\_U)

These instructions multiply the two sets of 32-bit binary data specified.

| Ladder | ST                                                    |                                                           |

## Processing details

- These instructions multiply the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the operation result in the device specified by (d).

- When (d) is a bit device, only the lower 32 bits of the operation result are stored. If the upper 32 bits of the operation result are required, temporarily store the result in a word device, and transfer the data stored in (d)+2 and (d)+3 to the specified bit devices.

### Ex.

Operation result when (d) is a bit device

- K1...Lower 4 bits (b0 to b3)
- K4...Lower 16 bits (b0 to b15)
- K8...Lower 32 bits (b0 to b31)

## Operation error

There is no operation error.

# Dividing 32-bit binary data

## D/(P)(\_U)

These instructions perform division between the two sets of 32-bit binary data specified.

| Ladder | ST                                                          |                                                                 |

| (s2)    | ○                                | ○    | ○                                     | ○           | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                                | —    | ○                                     | —           | — | ○           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions divide the 32-bit binary data in the device specified by (s1) by the 32-bit binary data in the device specified by (s2), and store the operation result in the device specified by (d).

- As the operation result when a word device is specified, the quotient and remainder are stored in 64 bits. The quotient is stored in lower 32 bits, and the remainder is stored in upper 32 bits. When a bit device is specified, only quotient is stored in 32 bits.

## Operation error

| Error code (SD0) | Description                                               |
|------------------|-----------------------------------------------------------|
| 3280H            | The value (divisor) in the device specified by (s2) is 0. |

# Adding BCD 4-digit data

## B+(P) [when two operands are set]

These instructions add the two sets of BCD 4-digit data specified.

| Ladder | ST                                                               |
|--------|------------------------------------------------------------------|

| (d)     | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | —        | — | —  | —      |

### Processing details

- These instructions add the BCD 4-digit data in the device specified by (s1) and the BCD 4-digit data in the device specified by (s2), and store the operation result in the device specified by (d).

- If the result exceeds 9999, the carry bit is ignored. In this case, SM700 does not turn on.

## Operation error

| DB-P        |                     |

## Setting data

## Description, range, data type

| Operand | Description                                                         | Range         | Data type   | Data type (label) |
|---------|---------------------------------------------------------------------|---------------|-------------|-------------------|
| (s)     | Subtrahend data or the start device where subtrahend data is stored | 0 to 99999999 | BCD 8-digit | ANY32             |
| (d)     | Minuend data or the start device where minuend data is stored       | 0 to 99999999 | BCD 8-digit | ANY32             |

## Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                                | ○   | ○                                     | ○          | ○ | ○           | ○  | ○                      | ○        | — | —  | —      |
| (d)     | ○                                | ○   | ○                                     | ○          | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions subtract the BCD 8-digit data in the device specified by (s) from the BCD 8-digit data in the device specified by (d), and store the operation result in the device specified by (d).

(d)+1, (s)+1: Upper 4 digits

(d), (s): Lower 4 digits

- If an underflow occurs, the result will be as follows. In this case, SM700 does not turn on.

## Operation error

| Error code (SD0) | Description                                                                     |
|------------------|---------------------------------------------------------------------------------|
| 3285H            | The BCD data in the device specified by (s) is out of the range, 0 to 99999999. |

## Processing details

- These instructions multiply the BCD 8-digit data in the device specified by (s1) by the BCD 8-digit data in the device specified by (s2), and store the operation result in the device specified by (d).

- When (d) is a bit device, only the lower 8 digits (lower 32 bits) of the operation result are stored.

### Ex.

Operation result when (d) is a bit device

- K1...Lower 1 digit (b0 to b3)
- K4...Lower 4 digits (b0 to b15)
- K8...Lower 8 digits (b0 to b31)

## Operation error

| Error code (SD0) | Description                                                                      |
|------------------|----------------------------------------------------------------------------------|
| 3285H            | The BCD data in the device specified by (s1) is out of the range, 0 to 99999999. |
|                  | The BCD data in the device specified by (s2) is out of the range, 0 to 99999999. |

## Dividing BCD 8-digit data

### DB/(P)

These instructions perform division between the two sets of BCD 8-digit data specified.

| Ladder | ST            |
|--------|---------------|
|        | Not supported |

### FBD/LD

(□ is to be replaced by either of the following: DBDIVISION, DBDIVISIONP.)

### ■Execution condition

## Processing details

- These instructions divide the BCD 8-digit data in the device specified by (s1) by the BCD 8-digit data in the device specified by (s2), and store the operation result in the device specified by (d).

(d)+1, (d)+3: Upper 4 digits

(d), (d)+2: Lower 4 digits

- As the operation result, the quotient and remainder are stored in 64 bits.
  - Quotient (BCD 8 digits)---Stored in lower 32 bits.
  - Remainder (BCD 8 digits)---Stored in upper 32 bits.
- When (d) is a bit device, the remainder is not stored.

## Operation error

| Error code (SD0) | Description                                                                      |
|------------------|----------------------------------------------------------------------------------|

## Processing details

- These instructions add the (n) points of 16-bit binary data from the device specified by (s1) and the (n) points of 16-bit binary data from the device specified by (s2) or the constant, and store the operation result in the device specified by (d) and later.
- Specify data in units of 16 bits.

**Ex.**

When a device is specified by (s2) (signed value specification)

When a constant is specified by (s2) (signed value specification)

- If an overflow occurs, the result will be as follows. In this case, SM700 does not turn on.

| When a signed value is specified |   |                | When an unsigned value is specified |                    |  |
|----------------------------------|---|----------------|-------------------------------------|--------------------|--|
| K32767<br>(H7FFF)                | + | K2<br>(H0002)  | ⇒                                   | K-32767<br>(H8001) |  |
| K-32767<br>(H8001)               | + | K-2<br>(HFFFE) | ⇒                                   | K32767<br>(H7FFF)  |  |
| K65535<br>(HFFFF)                | + | K1<br>(H0001)  | ⇒                                   | K0<br>(H0000)      |  |

## Operation error

| Error code<br>(SD0) | Description                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H               | The device ranges starting from the ones specified by (s1) and (d) are overlapping (except when the same device is specified for (s1) and (d)). |
|                     | The device ranges starting from the ones specified by (s2) and (d) are overlapping (except when the same device is specified for (s2) and (d)). |

# Subtracting 16-bit binary block data

## BK-(P)(\_U)

These instructions perform subtraction between the two 16-bit binary data blocks specified.

| Ladder | ST                                                          |                                                                 |
|--------|-------------------------------------------------------------|-----------------------------------------------------------------|

## Processing details

- These instructions subtract the (n) points of 16-bit binary data from the device specified by (s2) or the constant from the (n) points of 16-bit binary data from the device specified by (s1), and store the operation result in the device specified by (d) and later.
- Specify data in units of 16 bits.

### Ex.

When a device is specified by (s2)

When a constant is specified by (s2)

- If an overflow occurs, the result will be as follows. In this case, SM700 does not turn on.

| When a signed value is specified |   |                | When an unsigned value is specified |                    |                                     |
|----------------------------------|---|----------------|-------------------------------------|--------------------|-------------------------------------|
| K-32768<br>(H8000)               | - | K2<br>(H0002)  | ⇒                                   | K32766<br>(H7FFE)  |                                     |
| K32767<br>(H7FFF)                | - | K-2<br>(HFFFE) | ⇒                                   | K-32767<br>(H8001) |                                     |
|                                  |   |                |                                     | K0<br>(H0000)      | - K1<br>(H0001) ⇒ K65535<br>(HFFFF) |

## Operation error

| Error code<br>(SD0) | Description                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H               | The device ranges starting from the ones specified by (s1) and (d) are overlapping (except when the same device is specified for (s1) and (d)). |
|                     | The device ranges starting from the ones specified by (s2) and (d) are overlapping (except when the same device is specified for (s2) and (d)). |

## Adding 32-bit binary block data

### DBK+(P)(\_U)

These instructions add the two 32-bit binary data blocks specified.

| Ladder | ST                                                          |                                                                 |
|--------|-------------------------------------------------------------|-----------------------------------------------------------------|
|        | ENO:=DBKPLUS(EN,s1,s2,n,d);<br>ENO:=DBKPLUSP(EN,s1,s2,n,d); | ENO:=DBKPLUS_U(EN,s1,s2,n,d);<br>ENO:=DBKPLUSP_U(EN,s1,s2,n,d); |

### FBD/LD

(□ is to be replaced by any of the following: DBKPLUS, DBKPLUSP, DBKPLUS\_U, DBKPLUSP\_U.)

### Execution condition

| Instruction      | Execution condition |
|------------------|---------------------|
| DBK+<br>DBK+_U   |                     |
| DBK+P<br>DBK+P_U |                     |

### Setting data

### Description, range, data type

| Operand |           | Description                                                                   | Range                     | Data type              | Data type (label)     |
|---------|-----------|-------------------------------------------------------------------------------|---------------------------|------------------------|-----------------------|
| (s1)    | DBK+(P)   | First addend data or the start device where the first addend data is stored   | -2147483648 to 2147483647 | 32-bit signed binary   | ANY32_S <sup>*1</sup> |
|         | DBK+(P)_U |                                                                               | 0 to 4294967295           | 32-bit unsigned binary | ANY32_U <sup>*1</sup> |
| (s2)    | DBK+(P)   | Second addend data or the start device where the second addend data is stored | -2147483648 to 2147483647 | 32-bit signed binary   | ANY32_S <sup>*1</sup> |
|         | DBK+(P)_U |                                                                               | 0 to 4294967295           | 32-bit unsigned binary | ANY32_U <sup>*1</sup> |
| (d)     | DBK+(P)   | Start device for storing the operation result                                 | —                         | 32-bit signed binary   | ANY32_S <sup>*1</sup> |
|         | DBK+(P)_U |                                                                               |                           | 32-bit unsigned binary | ANY32_U <sup>*1</sup> |
| (n)     |           | Number of data points                                                         | 0 to 65535                | 16-bit unsigned binary | ANY16                 |
| EN      |           | Execution condition                                                           | —                         | Bit                    | BOOL                  |
| ENO     |           | Execution result                                                              | —                         | Bit                    | BOOL                  |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

### Applicable devices

| Operand | Bit                              |      | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|------|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□□, J□□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s1)    | —                                | —    | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                                | —    | ○                                     | —          | — | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                                | —    | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                                | ○    | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions add the (n) points of 32-bit binary data from the device specified by (s1) and the (n) points of 32-bit binary data from the device specified by (s2) or the constant, and store the operation result in the device specified by (d) and later.
- Specify data in units of 32 bits.

**Ex.**

When a device is specified by (s2) (signed value specification)

When a constant is specified by (s2) (signed value specification)

- Operation is possible when the same device is specified by (s1) or (s2) and (d). However, if the device range of (n) points from (s1) or (s2) and the device range of (n) points from (d) are partly overlapped, an error results.

**Ex.**

When the four points of device from that specified by (s2) and (d) exactly match

(1) Operation is possible because they exactly match.

When four points of device from that specified by (s2) and (d) are partly overlapped

(1) An operation error results because they partly match.

- If (n) is 0, no processing is performed.
- If an overflow occurs, the result will be as follows. In this case, SM700 does not turn on.

| When a signed value is specified                                                                                                            | When an unsigned value is specified                      |
|---------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| K2147483647 (H7FFFFFFF) + K2 (H00000002) → K-2147483647 (H80000001)<br>K-2147483647 (H80000001) + K-2 (HFFFFFFFE) → K2147483647 (H7FFFFFFF) | K4294967295 (HFFFFFFF) + K1 (H00000001) → K0 (H00000000) |

| Error code (SD0) | Description                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H            | The device ranges starting from the ones specified by (s1) and (d) are overlapping (except when the same device is specified for (s1) and (d)). |
|                  | The device ranges starting from the ones specified by (s2) and (d) are overlapping (except when the same device is specified for (s2) and (d)). |

# Subtracting 32-bit binary block data

## DBK-(P)(\_U)

These instructions perform subtraction between the two 32-bit binary data blocks specified.

| Ladder | ST                                                            |                                                                   |
|--------|---------------------------------------------------------------|-------------------------------------------------------------------|
|        | ENO:=DBKMINUS(EN,s1,s2,n,d);<br>ENO:=DBKMINUSP(EN,s1,s2,n,d); | ENO:=DBKMINUS_U(EN,s1,s2,n,d);<br>ENO:=DBKMINUSP_U(EN,s1,s2,n,d); |

## FBD/LD

(□ is to be replaced by any of the following: DBKMINUS, DBKMINUSP, DBKMINUS\_U, DBKMINUSP\_U.)

## Execution condition

| Instruction      | Execution condition |
|------------------|---------------------|
| DBK-<br>DBK-_U   |                     |
| DBK-P<br>DBK-P_U |                     |

## Setting data

## Description, range, data type

| Operand |           | Description                                                         | Range                     | Data type              | Data type (label)     |

## Processing details

- These instructions subtract the (n) points of 32-bit binary data from the device specified by (s2) or the constant from the (n) points of 32-bit binary data from the device specified by (s1), and store the operation result in the device specified by (d) and later.
- Specify data in units of 32 bits.

### Ex.

When a device is specified by (s2) (signed value specification)

When a constant is specified by (s2) (signed value specification)

- Operation is possible when the same device is specified by (s1) or (s2) and (d). However, if the device range of (n) points from (s1) or (s2) and the device range of (n) points from (d) are partly overlapped, an error results.

### Ex.

When the four points of device from that specified by (s2) and (d) exactly match

(1) Operation is possible because they exactly match.

When four points of device from that specified by (s2) and (d) are partly overlapped

(1) An operation error results because they partly match.

- If (n) is 0, no processing is performed.
- If an overflow occurs, the result will be as follows. In this case, SM700 does not turn on.

| When a signed value is specified |   | When an unsigned value is specified |                               |
|----------------------------------|---|-------------------------------------|-------------------------------|
| K2147483647<br>(H7FFFFFFF)       | - | K-2<br>(HFFFFFFFE)                  | → K-2147483647<br>(H80000001) |
| K-2147483647<br>(H80000001)      | - | K2<br>(H00000002)                   | → K2147483647<br>(H7FFFFFFF)  |
|                                  |   | K0<br>(H00000000)                   | -                             |
|                                  |   | K1<br>(H00000001)                   | → K4294967295<br>(HFFFFFFF)   |

## Operation error

| Error code<br>(SD0) | Description                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H               | The device ranges starting from the ones specified by (s1) and (d) are overlapping (except when the same device is specified for (s1) and (d)). |
|                     | The device ranges starting from the ones specified by (s2) and (d) are overlapping (except when the same device is specified for (s2) and (d)). |

# Incrementing 16-bit binary data

## INC(P)(\_U)

These instructions increment the specified 16-bit binary data by one.

| Ladder                                                                            | ST                                  |                                         |

#### Setting data

#### ■Description, range, data type

| Operand | Description                                                     | Range           | Data type            | Data type (label) |
|---------|-----------------------------------------------------------------|-----------------|----------------------|-------------------|
| (s)     | Logical AND data or the device where logical AND data is stored | -32768 to 32767 | 16-bit signed binary | ANY16             |
| (d)     | Device for storing the operation result                         | -32768 to 32767 | 16-bit signed binary | ANY16             |

#### ■Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□□, J□□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | ○                                | ○   | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                                | ○   | ○                                     | ○          | ○ | —           | —  | ○                      | —        | — | —  | —      |

#### Processing details

- These instructions perform an AND operation (bit-by-bit) on the 16-bit binary data in the device specified by (d) and the 16-bit binary data in the device specified by (s), and store the operation result in the device specified by (d).

- When a bit device is specified, the instruction performs an operation by assuming that the ones after the number of digit-specified points are 0.

#### Operation error

There is no operation error.

## WAND(P) [when three operands are set]

These instructions perform an AND operation on the two sets of 16-bit binary data specified.

| Ladder                                                                            | ST                                                        |

## Processing details

- These instructions perform an AND operation (bit-by-bit) on the 16-bit binary data in the device specified by (s1) and the 16-bit binary data in the device specified by (s2), and store the operation result in the device specified by (d).

- When a bit device is specified, the instruction performs an operation by assuming that the ones after the number of digit-specified points are 0.

## Operation error

There is no operation error.

# Performing an AND operation on 32-bit data

## Processing details

- These instructions perform an OR operation (bit-by-bit) on the 16-bit binary data in the device specified by (d) and the 16-bit binary data in the device specified by (s), and store the operation result in the device specified by (d).

- When a bit device is specified, the instruction performs an operation by assuming that the ones after the number of digit-specified points are 0.

## Operation error

There is no operation error.

## WOR(P) [when three operands are set]

These instructions perform an OR operation on the two sets of 16-bit binary data specified.

| Ladder | ST                                                      |
|--------|---------------------------------------------------------|
|        | <pre>ENO:=WOR(EN,s1,s2,d); ENO:=WORP(EN,s1,s2,d);</pre> |
| FBD/LD |                                                         |
|        |                                                         |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| WOR         |                     |
| WORP        |                     |

### Processing details

- These instructions perform an OR operation (bit-by-bit) on the 32-bit binary data in the device specified by (d) and the 32-bit binary data in the device specified by (s), and store the operation result in the device specified by (d).

- When a bit device is specified, the instruction performs an operation by assuming that the ones after the number of digit-specified points are 0.

## Operation error

There is no operation error.

## DOR(P) [when three operands are set]

These instructions perform an OR operation on the two sets of 32-bit binary data specified.

| Ladder                                                                            | ST                                                      |

| (n)                | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | —      |

\*1 The same device number can be specified for (s1) and (d) or (s2) and (d).

## Processing details

- These instructions perform an OR operation on the (n) points of data from the device specified by (s1) and the (n) points of data from the device specified by (s2), and store the operation result in the device specified by (d) and later.

- A constant from -32768 to 32767 (16-bit signed binary) can be specified for (s2).

## Operation error

| Error code (SD0) | Description                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2821H            | The device ranges starting from the ones specified by (s1) and (d) are partially overlapping (except when the same device is specified for (s1) and (d)). |
|                  | The device ranges starting from the ones specified by (s2) and (d) are partially overlapping (except when the same device is specified for (s2) and (d)). |

## Performing an XOR operation on 16-bit data

### WXOR(P) [when two operands are set]

These instructions perform an XOR operation on the two sets of 16-bit binary data specified.

| Ladder                                                                            | ST                                                                 |

## Processing details

- These instructions perform an XNOR operation on the 32-bit binary data in the device specified by (s1) and the 32-bit binary data in the device specified by (s2), and store the operation result in the device specified by (d).

- When a bit device is specified, the instruction performs an operation by assuming that the ones after the number of digit-specified points are 0.

## Operation error

There is no operation error.

# Performing an XNOR operation on 16-bit block data

## BKXNR(P)

These instructions perform an XNOR operation on the two 16-bit binary data blocks specified.

| Ladder | ST                                                      |

| (n)     | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | —      |

### Processing details

- These instructions set the 'n'th bit in the word device specified by (d) to 1.

(1) Set b6 of D10 to 1.

- If (n) exceeds 15, the instruction sets lower 4 bits of data.

## Operation error

There is no operation error.

## Resetting a bit in the word device

### BRST(P)

These instructions reset the 'n'th bit in the specified word device to 0.

| Ladder | ST                                                |
|--------|---------------------------------------------------|
|        | <pre>ENO:=BRST(EN,n,d); ENO:=BRSTP(EN,n,d);</pre> |

## Processing details

- These instructions extract the bit data at the position specified by (s2) of the word device specified by (s1), and write it to the bit device specified by (d).

(1) (s2) bit (When (s2)=5)

- The bit device specified by (d) turns off when the extracted bit data is 0 and turns on when the bit data is 1.
- Specify the bit position (0 to 15) of the word data in (s2). When 16 or a greater value is specified in (s2), the remainder of  $(s2) \div 16$  becomes the bit position.

**Ex.**

When (s2)=18: The remainder of  $18 \div 16$  is 2, and therefore the data in bit 2 will be extracted.

## Operation error

There is no operation error.

## Performing a 32-bit test

### DTEST(P)

These instructions extract the 'n'th bit in the specified double-word device.

| Ladder                                                                            | ST                                                          |

## Processing details

- These instructions extract the bit data at the position specified by (s2) of the double-word device specified by (s1), and write it to the bit device specified by (d).

(1) (s2) bit (When (s2)=21)

- The bit device specified by (d) turns off when the extracted bit data is 0 and turns on when the bit data is 1.
- Specify the bit position (0 to 31) of the double-word data in (s2). When 32 or a greater value is specified in (s2), the remainder of  $(s2) \div 32$  becomes the bit position.

**Ex.**

When (s2)=34: The remainder of  $34 \div 32$  is 2, and therefore the data in bit 2 will be extracted.

## Operation error

There is no operation error.

# Batch-resetting bit devices

## BKRST(P)

These instructions reset the (n) points of bit devices starting from the bit device specified.

\*1 FX and FY cannot be used.

## Processing details

- These instructions shift the 16-bit binary data in the device specified by (d) to the right by (n) bit(s).
- The (n) bit(s) from the most significant bit is/are filled with 0(s).
- In SM700 (carry flag), a value in a bit to the right of the shift target area is stored.

**Ex.**

When (n)=6

- When (d) is a bit device, bits are shifted to the right within the device range specified by digit specification.

**Ex.**

When (n)=4

- The number of bits actually to be shifted is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 8, 7 bits are shifted because 15 divided by 8 equals 1 with a remainder of 7.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are shifted by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are shifted to the right because 18 divided by 16 equals 1 with a remainder of 2.

## Operation error

There is no operation error.

## Shifting 16-bit binary data to the left by n bit(s)

### SFL(P)

These instructions shift the 16-bit binary data in the specified device to the left by (n) bit(s). In the empty area after the shift, 0 is stored.

| Ladder                                                                            | ST                                      |

\*1 FX and FY cannot be used.

## Processing details

- This instruction shifts the 16-bit binary data in the device specified by (d) to the left by (n) bit(s).
- The (n) bit(s) from the least significant bit is/are filled with 0(s).
- In SM700 (carry flag), a value in a bit to the left of the shift target area is stored.

**Ex.**

When (n)=8

- When (d) is a bit device, bits are shifted to the left within the device range specified by digit specification.

**Ex.**

When (n)=5

- The number of bits actually to be shifted is the remainder of (n)÷(specified number of bits). For example, when (n) is 15 and the specified number of bits is 8, 7 bits are shifted because 15 divided by 8 equals 1 with a remainder of 7.
- Specify any value between 0 and 15 for (n). If a value 16 or larger is specified, the value is shifted by the remainder value of n÷16 to the left. For example, when (n) is 18, 2 bits are shifted to the left because 18 divided by 16 equals 1 with a remainder of 2.

## Operation error

There is no operation error.

# Shifting n-bit data to the right by one bit

## BSFR(P)

These instructions shift the (n) points of data starting from the specified device to the right by one bit. In the empty area after the shift, 0 is stored.

\*1 T, C, and ST cannot be used.

\*2 FX and FY cannot be used.

## Processing details

- These instructions shift bit data to the right by the (n2) bit(s) within the (n1) bits of data area starting from the device specified by (d).
- In SM700 (carry flag), a value in a bit to the right of the shift target area is stored.

### Ex.

When (n1)=10 and (n2)=4

- Specify (n1) and (n2) so that the following condition is satisfied:  $(n1) > (n2)$ . In the case of  $(n1) \leq (n2)$ , data is shifted by the value of the remainder of  $(n2) \div (n1)$ . However, if the remainder value is 0, no processing is performed.
- Specify (n1) within the range of 1 to 64.
- The (n2) bit(s) from the most significant bit is/are filled with 0(s). In the case of  $(n1) < (n2)$ , the bits are filled with 0s by the value of the remainder of  $(n2) \div (n1)$ .
- If (n1) or (n2) is 0, no processing is performed.

## Operation error

| Error code (SD0) | Description                                               |
|------------------|-----------------------------------------------------------|
| 3285H            | The value specified by (n1) is out of the range, 0 to 64. |

# Shifting n-bit data to the left by n bit(s)

## SFTBL(P)

These instructions shift the bit data to the left by (n2) bit(s) within (n1) bits starting from the specified device. In the empty area after the shift, 0 is stored.

\*1 T, C, and ST cannot be used.

\*2 FX and FY cannot be used.

## Processing details

- These instructions shift bit data to the left by the (n2) bit(s) within the (n1) bits of data area starting from the device specified by (d).
- In SM700 (carry flag), a value in a bit to the left of the shift target area is stored.

### Ex.

When (n1)=10 and (n2)=4

- Specify (n1) and (n2) so that the following condition is satisfied:  $(n1) > (n2)$ . In the case of  $(n1) \leq (n2)$ , data is shifted by the value of the remainder of  $(n2) \div (n1)$ . However, if the remainder value is 0, no processing is performed.
- Specify (n1) within the range of 1 to 64.
- The (n2) bit(s) from the least significant bit is/are filled with 0(s). In the case of  $(n1) < (n2)$ , the bits are filled with 0s by the value of the remainder of  $(n2) \div (n1)$ .
- If (n1) or (n2) is 0, no processing is performed.

## Operation error

| Error code (SD0) | Description                                               |
|------------------|-----------------------------------------------------------|
| 3285H            | The value specified by (n1) is out of the range, 0 to 64. |

## Shifting n-word data to the right by n word(s)

### SFTWR(P)

These instructions shift the word data to the right by (n2) word(s) within (n1) words starting from the specified device. In the empty area after the shift, 0 is stored.

| Ladder | ST                                                  |
|--------|-----------------------------------------------------|
|        | ENO:=SFTWR(EN,n1,n2,d);<br>ENO:=SFTWRP(EN,n1,n2,d); |
| FBD/LD |                                                     |
|        |                                                     |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| SFTWR       |                     |
| SFTWRP      |                     |

### Setting data

## Processing details

These instructions convert the BCD 4-digit data (0 to 9999) in the device specified by (s) to 16-bit binary data, and store the converted data in the device specified by (d).

(1) Always becomes "0".

## Operation error

| Error code (SD0) | Description                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------|
| 3281H            | A value other than 0 to 9 exists at any digit of the value in the device specified by (s). <sup>*1</sup> |

<sup>\*1</sup> Turning on SM754 (BIN, DBIN instruction error disable flag) can prevent this error from being detected.

If the specified value is out of the valid range, the BIN(P) instruction is not executed regardless of the status (on/off) of SM754.

The BIN(P) instruction does not execute the next operation until the command (execution condition) is turned off and on regardless of the presence of an error.

# Converting BCD 8-digit data to 32-bit binary data

## DBIN(P)

These instructions convert the specified BCD 8-digit data to 32-bit binary data.

| Ladder | ST                                                |
|--------|---------------------------------------------------|
|        | <pre>ENO:=DBIN(EN,s,d); ENO:=DBINP(EN,s,d);</pre> |

## FBD/LD

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| DBIN        |                     |
| DBINP       |                     |

## Setting data

## Processing details

- These instructions convert the single-precision real number in the device specified by (s) to 16-bit signed binary data, and store the converted data in the device specified by (d).
- After conversion, the first digit after the decimal point of the single-precision real number is rounded off.
- When an input value is set using the engineering tool, a rounding error may occur. For the precautions on setting an input value using the engineering tool, refer to the following.

☞ Page 40 Precautions

### Ex.

When M0 turns on, the single-precision real number stored in D0 and D1 are converted to 16-bit signed binary data, and the converted data is stored in D100.

## Operation error

## Processing details

- These instructions convert the single-precision real number in the device specified by (s) to 32-bit signed binary data, and store the converted data in the device specified by (d).
- After conversion, the first digit after the decimal point of the single-precision real number is rounded off.
- When an input value is set using the engineering tool, a rounding error may occur. For the precautions on setting an input value using the engineering tool, refer to the following.

☞ Page 40 Precautions

### Ex.

When M0 turns on, the single-precision real number stored in D0 and D1 are converted to 32-bit signed binary data, and the converted data is stored in D100 and D101.

## Operation error

## Processing details

- These instructions convert the double-precision real number in the device specified by (s) to 16-bit unsigned binary data, and store the converted data in the device specified by (d).
- After conversion, the first digit after the decimal point of the double-precision real number is rounded off.
- When an input value is set using the engineering tool, a rounding error may occur. For the precautions on setting an input value using the engineering tool, refer to the following.

☞ Page 40 Precautions

### Ex.

When M0 turns on, the double-precision real number stored in D0 to D3 are converted to 16-bit unsigned binary data, and the converted data is stored in D100.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                         |

### Point

The INT2UINT(P) instruction is used in programming using labels. The purpose of using this instruction is to match the data type of the specified label with the data type that can be specified by the instruction operand. In programming using devices, use of the INT2UINT(P) instruction is not required.

## Processing details

- These instructions convert the 16-bit signed binary data (ANY16\_S) in the label specified by (s) to 16-bit unsigned binary data (ANY16\_U), and store the converted data in the label specified by (d).
- The following figure shows a program example using the INT2UINT(P) instruction.

### Ex.

The +\_U instruction requires ANY16\_U to be specified by the operand, and therefore, before the +\_U instruction is executed, the INT2UINT instruction is used to convert wLabel0 of ANY16\_S to uLabel1 of ANY16\_U.

The value in wLabel0 is stored in uLabel1 as is.

bSwitchA: Bit

wLabel0: Word [signed]

uLabel0, uLabel1: Word [unsigned]/bit string [16 bits]

(1) The value is stored as is.

(2) The data type of the value is converted to the one of the operand in the +\_U instruction, and the operation starts.

## Operation error

There is no operation error.

# Converting 16-bit signed binary data to 32-bit signed binary data

## INT2DINT(P)

These instructions convert the specified 16-bit signed binary data to 32-bit signed binary data.

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|
|        | <pre>ENO:=INT2DINT(EN,s,d); ENO:=INT2DINTP(EN,s,d);</pre> |

## FBD/LD

### Point

The UINT2INT(P) instruction is used in programming using labels. The purpose of using this instruction is to match the data type of the specified label with the data type that can be specified by the instruction operand. In programming using devices, use of the UINT2INT(P) instruction is not required.

## Processing details

- These instructions convert the 16-bit signed binary data (ANY16\_U) in the label specified by (s) to 16-bit unsigned binary data (ANY16\_S), and store the converted data in the label specified by (d).
- The following figure shows a program example using the UINT2INT(P) instruction.

### Ex.

The + instruction requires ANY16\_S to be specified by the operand, and therefore, before the + instruction is executed, the UINT2INT instruction is used to convert uLabel0 of ANY16\_U to wLabel1 of ANY16\_S.

The value in uLabel0 is stored in wLabel1 as is.

bSwitchA: Bit

wLabel0, wLabel1: Word [signed]

uLabel0: Word [unsigned]/bit string [16 bits]

(1) The value is stored as is.

(2) The data type of the value is converted to the one of the operand in the + instruction, and the operation starts.

## Operation error

There is no operation error.

# Converting 16-bit unsigned binary data to 32-bit signed binary data

### Point

The DINT2UDINT(P) instruction is used in programming using labels. The purpose of using this instruction is to match the data type of the specified label with the data type that can be specified by the instruction operand.

In programming using devices, use of the DINT2UDINT(P) instruction is not required.

## Processing details

- These instructions convert the 32-bit signed binary data (ANY32\_S) in the label specified by (s) to 32-bit unsigned binary data (ANY32\_U), and store the converted data in the label specified by (d).
- The following figure shows a program example using the DINT2UDINT(P) instruction.

### Ex.

The D+\_U instruction requires ANY32\_U to be specified by the operand, and therefore, before the D+\_U instruction is executed, the DINT2UDINT instruction is used to convert dLabel0 of ANY32\_S to udLabel1 of ANY32\_U.

The value in dLabel0 is stored in udLabel1 as is.

bSwitchA: Bit

dLabel0: Double word [signed]

udLabel0, udLabel1: Double word [unsigned]/bit string [32 bits]

(1) The value is stored as is.

(2) The data type of the value is converted to the one of the operand in the D+\_U instruction, and the operation starts.

## Operation error

There is no operation error.

# Converting 32-bit unsigned binary data to 16-bit signed binary data

## Processing details

These instructions convert the 32-bit unsigned binary data in the device specified by (s) to 16-bit unsigned binary data, and store the converted data in the device specified by (d).

### Ex.

When M0 turns on, the 32-bit unsigned binary data stored in D0 and D1 is converted to 16-bit unsigned binary data, and the converted data is stored in D100.

(1) Stored in the lower 16 bits.

## Operation error

There is no operation error.

# Converting 32-bit unsigned binary data to 32-bit signed binary data

## UDINT2DINT(P)

These instructions convert the specified 32-bit unsigned binary data to 32-bit signed binary data.

| Ladder | ST                                                            |
|--------|---------------------------------------------------------------|
|        | <pre>ENO:=UDINT2DINT(EN,s,d); ENO:=UDINT2DINTP(EN,s,d);</pre> |
| FBD/LD |                                                               |
|        |                                                               |

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| UDINT2DINT  |                     |
| UDINT2DINTP |                     |

## Setting data

## Description, range, data type

| Operand | Description                                              | Range           | Data type              | Data type (label) |
|---------|----------------------------------------------------------|-----------------|------------------------|-------------------|
| (s)     | Binary data or the label where the binary data is stored | 0 to 4294967295 | 32-bit unsigned binary | ANY32_U           |
| (d)     | Label for storing the converted binary data              | —               | 32-bit signed binary   | ANY32_S           |
| EN      | Execution condition                                      | —               | Bit                    | BOOL              |
| ENO     | Execution result                                         | —               | Bit                    | BOOL              |

## Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |

| (d)     | ○                                | ○   | ○                                     | ○          | ○ | ○           | ○  | ○                      | —        | — | —  | —      |

## Point

The UDINT2DINT(P) instruction is used in programming using labels. The purpose of using this instruction is to match the data type of the specified label with the data type that can be specified by the instruction operand.

In programming using devices, use of the UDINT2DINT(P) instruction is not required.

## Processing details

- These instructions convert the 32-bit signed binary data (ANY32\_U) in the label specified by (s) to 32-bit unsigned binary data (ANY32\_S), and store the converted data in the label specified by (d).
- The following figure shows a program example using the UDINT2DINT(P) instruction.

### Ex.

The D+ instruction requires ANY32\_S to be specified by the operand, and therefore, before the D+ instruction is executed, the UDINT2DINT instruction is used to convert udLabel0 of ANY32\_U to dLabel1 of ANY32\_S.

The value in udLabel0 is stored in dLabel1 as is.

bSwitchA: Bit

dLabel0, dLabel1: Double word [signed]

udLabel0: Double word [unsigned]/bit string [32 bits]

(1) The value is stored as is.

(2) The data type of the value is converted to the one of the operand in the D+ instruction, and the operation starts.

## Operation error

There is no operation error.

# Converting 16-bit binary data to Gray code data

## GRY(P)(\_U)

These instructions convert the specified 16-bit binary data to 16-bit binary Gray code data.

| Ladder                                                                            | ST                                      |                                             |

### ■Setting method of (s) for when SM705 (Number of conversion digits selection) is off

Set decimal ASCII data with the fixed number of digits in (s) to (s)+2.

ASCII S: Sign data of ASCII code

ASCII 10<sup>4</sup>: Ten-thousands place of ASCII code

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- The ASCII data in the device specified by (s) to (s)+2 is within the range from -32768 to 32767 for the DABIN(P) instruction, and it is within the range from 0 to 65535 for the DABIN(P)\_U instruction.
- The data of (s)+3 or later is ignored.
- As sign data, set 20H (space) when the ASCII data is positive, and set 2DH (-) when the data is negative. (If a value other than 20H and 2DH is set, the data will be processed as positive data.)
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H or 00H is set in each place of ASCII code, the value will be processed as 30H.

#### Ex.

"-25108" is set in (s) when the DABIN(P) instruction is used

## ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set decimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set if the integral part has the maximum number of digits (5 digits).

The following table lists the setting method of (s).

| Value to be set in (s)                                                                                 | Data of (s) to (s)+2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Value to be set in (s) | Data of (s) to (s)+2            |       |     |    |     |                       |  |                       |  |       |                       |  |                       |  |       |                       |  |                       |  |                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |     |       |     |    |     |                       |  |                                 |  |       |                       |  |                       |  |       |  |  |                       |  |

- The ASCII data in the device specified by (s) to (s)+2 is within the range from -32768 to 32767 for the DABIN(P) instruction, and it is within the range from 0 to 65535 for the DABIN(P)\_U instruction.
- Set 2DH (-) to lower byte of (s)+0 as sign data when the ASCII data is negative. Set an ASCII code of the uppermost digit instead of setting sign data when the ASCII data is 0 or positive.
- A value from 30H to 39H can be set in each place of ASCII code.
- If the value is positive and the numeric part has 5 digits, the data of the upper byte of (s)+2 or later is ignored. If the value is negative and the numeric part has 5 digits, the data of (s)+3 or later is ignored.
- If a value 20H is set in each place of ASCII code, the value is processed as 30H. If a value 00H is set, the value is processed as the end of the decimal ASCII data.
- In the following cases, 0 is stored.
  - The first character is 00H (NULL).
  - The first character is 2DH (-) and the second character is 00H (NULL).

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | Invalid data that cannot be converted are input in (s) to (s)+2. <ul style="list-style-type: none"> <li>The ASCII code of the first character is other than 2DH, 30H to 39H, 20H, and 00H.*1</li> <li>The ASCII code of the second character or later is other than 30H to 39H, 20H, and 00H.</li> <li>When the DABIN(P) instruction is used, ASCII data is out of the range from -32768 to 32767.</li> <li>When the DABIN(P)_U instruction is used, ASCII data is out of the range from 0 to 65535.</li> </ul> |

\*1 When SM705 (Number of conversion digits selection) is off, no error is detected no matter what value is set for the ASCII code of the first character.

# Converting decimal ASCII data to 32-bit binary data

## DDABIN(P)(\_U)

These instructions convert decimal ASCII data to 32-bit binary data.

| Ladder                                                                            | ST                                            |                                                   |

## Processing details

- These instructions convert the decimal ASCII data in the device areas specified by (s) and later to 32-bit binary data, and store the converted data in the device specified by (d).
- The setting method of the decimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Setting method of (s)                                                                      | Reference                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Off             | Set (s) with a fixed number of digits (a sign + 10 digits in the numeric part).            | Page 456 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| On              | Set (s) with a desired number of digits (maximum: a sign + 10 digits in the numeric part). | Page 457 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

### ■ Setting method of (s) for when SM705 (Number of conversion digits selection) is off

Set decimal ASCII data with the fixed number of digits in (s) to (s)+5.

ASCII S: Sign data of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>4</sup>: Ten-thousands place of ASCII code

ASCII 10<sup>5</sup>: Hundred-thousands place of ASCII code

ASCII 10<sup>6</sup>: Millions place of ASCII code

ASCII 10<sup>7</sup>: Ten-millions place of ASCII code

ASCII 10<sup>8</sup>: Hundred-millions place of ASCII code

ASCII 10<sup>9</sup>: Billions place of ASCII code

(1) Ignored.

(2) Upper 16 bits

(3) Lower 16 bits

- The ASCII data in the device specified by (s) to (s)+5 is within the range from -2147483648 to 2147483647 for the DDABIN(P) instruction, and it is within the range from 0 to 4294967295 for the DDABIN(P)\_U instruction. Any data stored in the upper bytes in the device specified by (s)+5 and data in the device specified by (s)+6 and later are ignored.
- As sign data, set 20H if the ASCII data is positive, and set 2DH if the data is negative. (If a value other than 20H and 2DH is set, the data will be processed as positive data.)
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H or 00H is set in each place of ASCII code, the value will be processed as 30H.

#### Ex.

"-1234543210" is set in (s) when the DDABIN(P) instruction is used

## ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set decimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set if the integral part has the maximum number of digits (10 digits).

The following table lists the setting method of (s).

| Value to be set in (s)                                                                                                                          | Data of (s) to (s)+5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Value to be set in (s) | Data of (s) to (s)+5            |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |  |  |  |  |  |                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |     |     |       |     |    |     |                       |  |                                 |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |                       |  |                       |  |  |       |  |  |                       |  |  |

ASCII 10<sup>1</sup>: Tens place of ASCII code  
⋮  
ASCII 10<sup>9</sup>: Billions place of ASCII code

- The ASCII data in the device specified by (s) to (s)+5 is within the range from -2147483648 to 2147483647 for the DDABIN(P) instruction, and it is within the range from 0 to 4294967295 for the DDABIN(P)\_U instruction.
- Set 2DH (-) to lower byte of (s)+0 as sign data when the ASCII data is negative. Set an ASCII code of the uppermost digit instead of setting sign data when the ASCII data is 0 or positive.
- A value from 30H to 39H can be set in each place of ASCII code.
- If the value is positive and the numeric part has 10 digits, the data stored in (s)+5 or later is ignored. If the value is negative and the numeric part has 10 digits, the data stored in the upper byte of (s)+5 or later is ignored.
- If a value 20H is set in each place of ASCII code, the value is processed as 30H. If a value 00H is set, the value is processed as the end of the decimal ASCII data.
- In the following cases, "0" is stored in (d).
  - The first character is 00H (NULL).
  - The first character is 2DH (-) and the second character is 00H (NULL).

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | Invalid data that cannot be converted are input in (s) to (s)+5. <ul style="list-style-type: none"><li>• The ASCII code of the first character is other than 2DH, 30H to 39H, 20H, and 00H.*<sup>1</sup></li><li>• The ASCII code of the second character or later is other than 30H to 39H, 20H, and 00H.</li><li>• When the DDABIN(P) instruction is used, ASCII data is out of the range from -2147483648 to 2147483647.</li><li>• When the DDABIN(P)_U instruction is used, ASCII data is out of the range from 0 to 4294967295.</li></ul> |

\*<sup>1</sup> When SM705 (Number of conversion digits selection) is off, no error is detected no matter what value is set for the ASCII code of the first character.

# Converting hexadecimal ASCII data to 16-bit binary data

12

## HABIN(P)

These instructions convert hexadecimal ASCII data to 16-bit binary data.

| Ladder | ST                                                  |

## Processing details

- These instructions convert the hexadecimal ASCII data stored in the device areas specified by (s) and later to 16-bit binary data, and store the converted data in the device specified by (d).
- The setting method of the hexadecimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Setting method of (s)                                        | Reference                                                                                    |
|-----------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Off             | Set (s) with a fixed number of digits (4 digits).            | Page 460 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| On              | Set (s) with a desired number of digits (maximum: 4 digits). | Page 460 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

### ■Setting method of (s) for when SM705 (Number of conversion digits selection) is off

- Set hexadecimal ASCII data with 4 digits (fixed) in (s) to (s)+1.

ASCII □: ASCII code (□th digit)

- The ASCII data in the device specified by (s) to (s)+1 is within the range from 0000H to FFFFH.
- The data of (s)+2 or later is ignored.
- A value from 30H to 39H and 41H to 46H can be set in each place of ASCII code.

#### Ex.

When 5A8DH is specified in (s)

### ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set hexadecimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set for the maximum number of digits (4 digits).

The following table lists the setting method of (s).

| Value to be set in (s) | Data of (s) to (s)+1                                                                                                                                                                                                                               | Value to be set in (s) | Data of (s) to (s)+1                                                                                                                                                                                                                                         |

ASCII □: ASCII code (□th digit)

- The ASCII data in the device specified by (s) to (s)+1 is within the range from 0000H to FFFFH.
- The data of (s)+2 or later is ignored.
- A value from 30H to 39H and 41H to 46H can be set in each place of ASCII code.
- If a value 00H is set in each place of ASCII code, the value will be processed as the end of the hexadecimal ASCII data.

## Processing details

- These instructions convert the hexadecimal ASCII data stored in the device specified by (s) and later to 32-bit binary data, and store the converted data in the device specified by (d).
- The setting method of the hexadecimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Setting method of (s)                                        | Reference                                                                                    |
|-----------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Off             | Set (s) with a fixed number of digits (8 digits).            | Page 463 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| On              | Set (s) with a desired number of digits (maximum: 8 digits). | Page 464 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

### ■ Setting method of (s) for when SM705 (Number of conversion digits selection) is off

- Set hexadecimal ASCII data with 8 digits (fixed) in (s) to (s)+3.

ASCII □: ASCII code (□th digit)

(1) Upper 16 bits

(2) Lower 16 bits

- The ASCII data in the device specified by (s) to (s)+3 is within the range from 00000000H to FFFFFFFFH.
- The data of (s)+4 or later is ignored.
- A value from 30H to 39H and 41H to 46H can be set in each place of ASCII code.

#### Ex.

When 5CB807E1H is specified in (s)

## ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set hexadecimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set for the maximum number of digits (8 digits).

The following table lists the setting method of (s).

| Value to be set in (s) | Data of (s) to (s)+3                                                                                                                                                                                                                                                                                                                                                                                                                  | Value to be set in (s) | Data of (s) to (s)+3 |         |       |         |         |       |         |         |       |     |         |                        |                                                                                                                                                                                                                                                                                                                                                                                                                      |     |         |         |       |         |         |       |         |         |       |         |         |

ASCII □: ASCII code (□th digit)

- The ASCII data in the device specified by (s) to (s)+3 is within the range from 00000000H to FFFFFFFFH.
- The data of (s)+4 or later is ignored.
- A value from 30H to 39H and 41H to 46H can be set in each place of ASCII code.
- If a value 00H is set in each place of ASCII code, the value will be processed as the end of the hexadecimal ASCII data.

## Operation error

# Converting decimal ASCII data to BCD 4-digit data

12

## DABCD(P)

These instructions convert decimal ASCII data to BCD 4-digit data.

| Ladder | ST                                         |
|--------|--------------------------------------------|
|        | ENO:=DABCD(EN,s,d);<br>ENO:=DABCDP(EN,s,d) |

## Processing details

- These instructions convert the decimal ASCII data stored in the device areas specified by (s) and later to BCD 4-digit data, and store the converted data in the device specified by (d).
- The setting method of the decimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Setting method of (s)                                        | Reference                                                                                    |
|-----------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Off             | Set (s) with a fixed number of digits (4 digits).            | Page 466 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| On              | Set (s) with a desired number of digits (maximum: 4 digits). | Page 467 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

### ■ Setting method of (s) for when SM705 (Number of conversion digits selection) is off

- Set decimal ASCII data the 4 digits (fixed) in (s) to (s)+1.

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- The ASCII data in the device specified by (s) to (s)+1 is within the range from 0 to 9999.
- The data of (s)+2 or later is ignored.
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H or 00H is set in each place of ASCII code, the value will be processed as 30H.

#### Ex.

When 8765 is specified in (s)

### ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set decimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set for the maximum number of digits (4 digits).

The following table lists the setting method of (s).

| Value to be set in (s) | Data of (s) to (s)+1                                                                                                                                                                                                                                                                                          | Value to be set in (s) | Data of (s) to (s)+1                                                                                                                                                                                                                                                                                    |

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- The ASCII data in the device specified by (s) to (s)+1 is within the range from 0 to 9999.
- The data of (s)+2 or later is ignored.
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H is set in each place of ASCII code, the value is processed as 30H. If a value 00H is set, the value is processed as the end of the decimal ASCII data.

## Processing details

- These instructions convert the decimal ASCII data stored in the device areas specified by (s) and later to BCD 8-digit data, and store the converted data in the device number specified by (d).
- The setting method of the decimal ASCII data to be set in (s) depends on the status of SM705 (Number of conversion digits selection).

| Status of SM705 | Setting method of (s)                                        | Reference                                                                                    |
|-----------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Off             | Set (s) with a fixed number of digits (8 digits).            | Page 469 Setting method of (s) for when SM705 (Number of conversion digits selection) is off |
| On              | Set (s) with a desired number of digits (maximum: 8 digits). | Page 470 Setting method of (s) for when SM705 (Number of conversion digits selection) is on  |

### ■ Setting method of (s) for when SM705 (Number of conversion digits selection) is off

- Set decimal ASCII data with 8 digits (fixed) in (s) to (s)+3.

ASCII 10<sup>7</sup>: Ten-millions place of ASCII code

ASCII 10<sup>6</sup>: Millions place of ASCII code

ASCII 10<sup>5</sup>: Hundred-thousands place of ASCII code

ASCII 10<sup>4</sup>: Ten-thousands place of ASCII code

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- The ASCII data in the device specified by (s) to (s)+3 is within the range from 0 to 99999999.
- The data of (s)+4 or later is ignored.
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H or 00H is set in each place of ASCII code, the value will be processed as 30H.

#### Ex.

When 87654321 is specified in (s)

## ■Setting method of (s) for when SM705 (Number of conversion digits selection) is on

Set decimal ASCII data with a desired number of digits (including 00H (NULL code)) in (s). Note that 00H (NULL code) is not required to be set for the maximum number of digits (8 digits).

The following table lists the setting method of (s).

| Value to be set in (s) | Data of (s) to (s)+3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Value to be set in (s) | Data of (s) to (s)+3  |       |     |    |     |                       |  |                       |  |       |                       |  |                       |  |       |                       |  |                       |  |       |     |  |                       |  |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |     |       |     |    |     |                       |  |                       |  |       |                       |  |                       |  |       |                       |  |                       |  |       |                       |  |                       |  |

ASCII 10<sup>7</sup>: Ten-millions place of ASCII code

ASCII 10<sup>6</sup>: Millions place of ASCII code

ASCII 10<sup>5</sup>: Hundred-thousands place of ASCII code

ASCII 10<sup>4</sup>: Ten-thousands place of ASCII code

ASCII 10<sup>3</sup>: Thousands place of ASCII code

ASCII 10<sup>2</sup>: Hundreds place of ASCII code

ASCII 10<sup>1</sup>: Tens place of ASCII code

ASCII 10<sup>0</sup>: Ones place of ASCII code

- The ASCII data in the device specified by (s) to (s)+3 is within the range from 0 to 99999999.
- The data of (s)+4 or later is ignored.
- A value from 30H to 39H can be set in each place of ASCII code.
- If a value 20H is set in each place of ASCII code, the value is processed as 30H. If a value 00H is set, the value is processed as the end of the decimal ASCII data.

## Operation error

# Converting decimal string data to 16-bit binary data

12

## VAL(P)(\_U)

These instructions convert strings to 16-bit binary data.

| Ladder | ST                                              |
|--------|-------------------------------------------------|
|        | ENO:=VAL(EN,s,d1,d2);<br>ENO:=VALP(EN,s,d1,d2); |

## Processing details

- These instructions convert the strings stored in the device numbers specified by (s) and later to 16-bit binary data, and store the number of digits in (d1) and converted binary data in the device specified by (d2). For conversion of strings to binary data, the data from the device number specified by (s) to the device number containing "00H" is processed as strings.

ASCII S: ASCII code (sign data)  
 ASCII □: ASCII code (□th character)

### Ex.

When a string "-123.45" (signed) is stored in the device specified by (s) or later

- The total number of characters of the string stored in the device specified by (s) is 2 to 8.
- Of the string stored in the device specified by (s), the number of characters in the decimal part is 0 to 5. Note, however, that the number must not exceed the total number of digits minus 3.
- A numerical string that can be converted to binary data ranges from -32768 to 32767 when a signed value is specified ignoring the decimal point or from 0 to 65535 when an unsigned value is specified. Numerical strings excluding signs and decimal points can be specified only within the range from 30H to 39H. (A value ignoring the decimal point... "-12345.6" for example becomes "-123456".)
- For the sign, "20H" can be set to indicate a positive numerical value, or "2DH" can be set to indicate a negative numerical value.
- "2EH" is set for the decimal point.
- The total number of digits stored in the device specified by (d1) includes all characters (including signs and decimal points) that represent a numerical value. The number of digits in the decimal part to be stored in the device specified by (d1)+1 represents the decimal part after 2EH(.) For the 16-bit binary data to be stored in the device specified by (d2), the string is converted to binary data by ignoring the decimal point and stored.
- If "20H" (space) or "30H" (0) exists between the sign and the first numerical value other than 0 in the string in the device specified by (s), the instruction performs conversion to binary data by ignoring "20H" and "30H".

### Ex.

When "20H" exists between the sign and the first numerical value other than 0 (when a signed value is specified)

**Ex.**

When "30H" exists between the sign and the first numerical value other than 0

## Operation error

## Processing details

- These instructions convert the strings stored in the device numbers specified by (s) and later to 32-bit binary data, and store the number of digits in (d1) and converted binary data in the device specified by (d2). For conversion of strings to binary data, the data from the device number specified by (s) to the device number containing "00H" is processed as strings.

### Ex.

When a string "-12345.678" (signed) is stored in the device specified by (s) or later

- The total number of characters of the string stored in the device specified by (s) is 2 to 13.
- Of the string stored in the device specified by (s), the number of characters in the decimal part is 0 to 10. Note, however, that the number must not exceed the total number of digits minus 3.
- The range of numerical strings that can be converted to binary is as follows. Numerical strings excluding signs and decimal points can be specified only within the range from 30H to 39H. (A value ignoring the decimal point..."-12345.6" for example becomes "-123456".)
- When a signed value ignoring the decimal point is specified: -2147483648 to 2147483647
- When an unsigned value ignoring the decimal point is specified: 0 to 4294967295
- For the sign, "20H" can be set to indicate a positive numerical value, or "2DH" can be set to indicate a negative numerical value.
- "2EH" is set for the decimal point.
- The total number of digits stored in the device specified by (d1) includes all characters (including signs and decimal points) that represent a numerical value. The number of digits in the decimal part to be stored in the device specified by (d1)+1 represents the decimal part after 2EH(.). For the 32-bit binary data to be stored in the device specified by (d2), the string is converted to binary data by ignoring the decimal point and stored.

- If "20H" (space) or "30H" (0) exists between the sign and the first numerical value other than 0 in the string in the device specified by (s), the instruction performs conversion to binary data by ignoring "20H" and "30H".

**Ex.**

When "20H" exists between the sign and the first numerical value other than 0 (when a signed value is specified)

**Ex.**

When "30H" exists between the sign and the first numerical value other than 0

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Processing details

- These instructions convert the hexadecimal ASCII data stored in the device by the number of characters specified by (n) after the device number specified by (s) and later to binary data, and store the converted data in the device number specified by (d) and later.

ASCII □: ASCII code (□th digit)

1 to 4: 1st to 4th digit

(n): Number of characters specified by (n)

- Setting the number of characters for (n) automatically determines the range of the string in the device specified by (s) and the device range in which the binary data in the device specified by (d) is stored.
- Processing is performed normally even if the device range in which the ASCII data to be converted and the device range for storing the converted binary data overlap.

- If the number of characters in the device specified by (n) is not a multiple of 4, "0H" is automatically stored after the specified number of the last device number among device numbers for storing the converted binary data.

### Ex.

When the number of characters in (n) is 9

(1) 0H is automatically stored.

- If the number of characters in the device specified by (n) is 0, no processing is performed.
- The ASCII code that can be specified by (s) must be in the range from "30H" to "39H" or "41H" to "46H".

## Operation error

| Error code (SD0) | Description                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3281H            | A character other than hexadecimal numerical string (an ASCII code other than "30H" to "39H" and "41H" to "46H") is set in the device specified by (s).                   |
| 3285H            | Out-of-range data is set in the device specified by (n). <ul style="list-style-type: none"> <li>The specified number of characters is not between 0 and 16383.</li> </ul> |

# Converting single-precision real number to BCD format data

## EMOD(P)

These instructions convert single-precision real number data to the BCD floating point format data.

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|

## Processing details

- These instructions convert the single-precision real number data stored in the device specified by (s1) to the BCD floating point format based on the number of decimal part digits stored in the device specified by (s2), and store the converted data in the device number specified by (d) and later.

- For the sign in (d) and the exponent sign in (d)+3, 0 is set for positive and 1 is set for negative.
- For the BCD exponent in (d)+4, a value between 0 and 38 is stored.
- The number of decimal part digits of the single-precision real number data in the device specified by (s1) is stored in the device specified by (s2). The example in the above figure shows the following.

3.25427  
 (s2)=3

- Six-digit BCD data, determined by rounding off the seventh digit, is stored in (d)+1 and (d)+2.

- A value of 0 to 7 can be set for the number of decimal part digits in the device specified by (s2).
- When an input value is set using the engineering tool, a rounding error may occur. Refer to the following for the precautions on setting input values using the engineering tool.

Page 40 Precautions

### Processing details

- These instructions store the binary value, corresponding to the bit which is set to 1 in the  $2^{(n)}$  bit data in the device specified by (s), in the device specified by (d).

- Specify a value 1 to 8 for (n).
- When (n)=0, no processing is performed and the values in the device specified by (d) remain unchanged.
- A bit device is treated as 1 bit, and a word device is treated as 16 bits.
- When two or more bits are 1, the upper bit position is used for processing.

## Processing details

- These instructions decode the data consisting of 0 to F specified by the lower 4 bits in the device specified by (s) to seven-segment display data, and store the decoded data in the device specified by (d).
- In the case of a bit device, (d) indicates the start device for storing 7-segment display data. In the case of a word device, it indicates the device number for storing the data.

**Ex.**

Bit device

The data in Y48 to Y4F does not change until the next data is output.

**Ex.**

Word device

(1) The upper 8 bits are filled with 0s.

(2) The seven-segment display data are stored in the lower 8 bits.

- The following is the truth table for the seven-segment display.

| (s)         |             | Seven-segment display | (d) |    |    |    |    |    |    |    | Display data |

## Processing details

- These instructions separate the lower (n) nibble(s) (4 bits/nibble) from the 16-bit binary data in the device specified by (s), and store each of the separated data in the lower 4 bits of the (n) points of data in the device specified by (d).

(1) Data storage area

(2) Filled with 0s.

- The upper 12 bits of the (n) points of data in the device specified by (d) are filled with 0s.
- Specify a value 1 to 4 for (n).
- When (n)=0, no processing is performed and the (n) points of data starting from the device specified by (d) remain unchanged.

## Operation error

| Error code (SD0) | Description                                             |
|------------------|---------------------------------------------------------|
| 3281H            | The value specified by (n) is out of the range, 0 to 4. |

## Combining data in units of 4 bits

### UNI(P)

These instructions store the lower 4 bits of the (n) points of 16-bit binary data in another 16-bit device.

| Ladder | ST                                                  |
|--------|-----------------------------------------------------|

## Processing details

- These instructions store the lower 4 bits of the (n) points of 16-bit binary data in the device specified by (s) in the 16-bit device specified by (d).

(1) Ignored.

(2) Data to be connected

- The upper bits (bits in the (4-n) nibble(s)) of data in the device specified by (d) are filled with 0s.
- Specify a value 1 to 4 for (n).
- When (n)=0, no processing is performed and the data in the device specified by (d) remain unchanged.

## Operation error

| Error code (SD0) | Description                                             |
|------------------|---------------------------------------------------------|
| 3281H            | The value specified by (n) is out of the range, 0 to 4. |

# Separating data in units of bits

## NDIS(P)

These instructions separate the data in units of bits. (The number of bits can be specified as desired.)

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|

| (d)     | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions separate the bits of data in the device specified by (s1) and later in units of bits specified by (s2), and store the separated data in the device range specified by (d) and later.

(s2) to (s2)+6: Number of bits specified by (s2) to (s2)+6

(1) The value, 0, indicates the end of setting.

(2) Ignored.

- Specify the value 1 to 16 for (s2).
- The device areas from the one specified by (s2) to the one storing "0" are processed.
- Specify the devices so that the range of the device where the separation target data is stored ((s1) and later) and the range of the device for storing the separated data ((d) and later) do not overlap. If they overlap, a correct operation result may not be obtained.
- Do not overlap the device numbers that are specified by (s1), (s2), and (d).

## Combining data in units of bits

### NUNI(P)

These instructions combine the data in units of bits. (The number of bits can be specified as desired.)

| Ladder | ST                                                        |
|--------|-----------------------------------------------------------|
|        | <pre>ENO:=NUNI(EN,s1,s2,d); ENO:=NUNIP(EN,s1,s2,d);</pre> |

| FBD/LD |
|--------|
|        |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| NUNI        |                     |
| NUNIP       |                     |

### Setting data

### ■Description, range, data type

| Operand | Description                                              | Range | Data type            | Data type (label)   |
|---------|----------------------------------------------------------|-------|----------------------|---------------------|
| (s1)    | Start device where the combination target data is stored | —     | 16-bit signed binary | ANY16 <sup>*1</sup> |
| (d)     | Start device for storing the combined data               | —     | 16-bit signed binary | ANY16 <sup>*1</sup> |
| (s2)    | Start device for storing the combination unit            | —     | 16-bit signed binary | ANY16 <sup>*1</sup> |
| EN      | Execution condition                                      | —     | Bit                  | BOOL                |
| ENO     | Execution result                                         | —     | Bit                  | BOOL                |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s1)    | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |
| (s2)    | —                                | —   | ○                                     | —           | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions combine the bits of data in the device specified by (s1) and later in units of bits specified by (s2), and store the combined data in the device specified by (d) and later.

(s2) to (s2)+6: Number of bits specified by (s2) to (s2)+6

(1) The value, 0, indicates the end of setting.

(2) Ignored.

- Specify the value 1 to 16 for (s2).
- The device areas from the one specified by (s2) to the one storing "0" are processed.
- Specify the devices so that the range of the device where the combination target data is stored ((s1) and later) and the range of the device for storing the combined data ((d) and later) do not overlap. If they overlap, a correct operation result may not be obtained.
- Do not overlap the device numbers that are specified by (s1), (s2), and (d).

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                    |

## Separating data in units of bytes

### WTOB(P)

These instructions separate 16-bit binary data into (n) bytes.

| Ladder | ST                                            |
|--------|-----------------------------------------------|
|        | ENO:=WTOB(EN,s,n,d);<br>ENO:=WTOBP(EN,s,n,d); |

| FBD/LD |
|--------|
|        |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| WTOB        |                     |
| WTOBP       |                     |

### Setting data

### ■Description, range, data type

| Operand | Description                                             | Range      | Data type              | Data type (label)   |
|---------|---------------------------------------------------------|------------|------------------------|---------------------|
| (s)     | Start device where the separation target data is stored | —          | 16-bit signed binary   | ANY16 <sup>*1</sup> |
| (d)     | Start device for storing the separated data             | —          | 16-bit signed binary   | ANY16 <sup>*1</sup> |
| (n)     | Number of data bytes to be separated                    | 0 to 65535 | 16-bit unsigned binary | ANY16               |
| EN      | Execution condition                                     | —          | Bit                    | BOOL                |
| ENO     | Execution result                                        | —          | Bit                    | BOOL                |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□G□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                                | ○   | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions separate the 16-bit binary data in the device specified by (s) and later into (n) bytes, and store the separated data in the device specified by (d) and later.

- (1) Upper byte  
 (2) Lower byte  
 (3) Upper byte data  
 (4) Lower byte data

\*1 Values after the decimal point are rounded up.

### Ex.

When (n) is 5, the data in the device specified by (s) (upper 8 bits) to (s)+2 (lower 8 bits) are stored in the device specified by (d) to (d)+4.

- (1) The data, FEH, is ignored when (n) is 5.  
 (2) When (n) is 5

- Setting the number of bytes for (n) automatically determines the range of 16-bit binary data specified by (s) and the range of the device specified by (d) for storing the separated data.
- If (n) is 0, no processing is performed.
- The upper 8 bits of the device specified by (d) are automatically filled with 00Hs.

### Ex.

When the byte data in D12 to D14 are stored in the lower 8 bits of D11 to D16

- (1) 00H is automatically stored.

- Even when the ranges of the device where the separation target data is stored and the device for storing the separated data overlap, the processing is performed normally.

| Range of the device where the separation target data is stored | Range of the device for storing the separated data |
|----------------------------------------------------------------|----------------------------------------------------|
| (s) to (s)+( $\frac{(n)}{2}-1$ )                               | (d)+0 to (d)+(n)-1                                 |

## Operation error

There is no operation error.

## Combining data in units of bytes

### BTOW(P)

These instructions combine the lower 8 bits of 16-bit binary data in units of words.

| Ladder | ST                                            |
|--------|-----------------------------------------------|
|        | ENO:=BTOW(EN,s,n,d);<br>ENO:=BTOWP(EN,s,n,d); |

| FBD/LD |
|--------|
|        |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| BTOW        |                     |
| BTOWP       |                     |

### Setting data

### ■Description, range, data type

| Operand | Description                                              | Range      | Data type              | Data type (label)   |
|---------|----------------------------------------------------------|------------|------------------------|---------------------|
| (s)     | Start device where the combination target data is stored | —          | 16-bit signed binary   | ANY16 <sup>*1</sup> |
| (d)     | Start device for storing the combined data               | —          | 16-bit signed binary   | ANY16 <sup>*1</sup> |
| (n)     | Number of data bytes to be combined                      | 0 to 65535 | 16-bit unsigned binary | ANY16               |
| EN      | Execution condition                                      | —          | Bit                    | BOOL                |
| ENO     | Execution result                                         | —          | Bit                    | BOOL                |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (d)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                                | ○   | ○                                     | ○          | ○ | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions combine the (n) bytes of lower 8 bits of 16-bit binary data in the device specified by (s) and later in units of words, and store the combined data in the device specified by (d) and later.
- The (n) bytes of upper 8 bits of 16-bit binary data in the device specified by (s) and later are ignored. When (n) is an odd number, the upper 8 bits of the device where 'n'th-byte data is stored are filled with 0s.

□: □th byte data

(1) The upper byte data are ignored.

\*1 Values after the decimal point are rounded up.

**Ex.**

When (n) is 5, the lower 8 bits of the data in the device specified by (s) to (s)+4 are combined and stored in the device specified by (d) to (d)+2.

(1) When (n) is 5

(2) Filled with 00H.

- Setting the number of bytes for (n) automatically determines the range of byte data in the device specified by (s) and the range of the device specified by (d) for storing the combined data.
- If (n) is 0, no processing is performed.
- The upper 8 bits in the device specified by (s) and later are ignored, and only the lower 8 bits are processed.
- Even when the ranges of the device where the combination target data is stored and the device for storing the combined data overlap, the processing is performed normally.

| Range of the device where the combination target data is stored | Range of the device for storing the combined data |
|-----------------------------------------------------------------|---------------------------------------------------|
| (s)+0 to (s)+(n)-1                                              | (d) to (d)+( $\frac{(n)}{2}-1$ )                  |

**Ex.**

When the lower 8 bits of D11 to D16 are stored in D12 to D14

## Operation error

There is no operation error.

# 12.7 Data Transfer Instructions

## Transferring 16-bit binary data

### MOV(P)

These instructions transfer the 16-bit binary data in the device specified.

| Ladder | ST                                        |
|--------|-------------------------------------------|
|        | ENO:=MOV(EN,s,d);<br>ENO:=MOV(P)(EN,s,d); |

### FBD/LD

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| MOV         |                     |
| MOV(P)      |                     |

### Setting data

### Description, range, data type

| Operand | Description                                                                               | Range           | Data type            | Data type (label) |
|---------|-------------------------------------------------------------------------------------------|-----------------|----------------------|-------------------|
| (s)     | Transfer source data or the number of the device where the transfer source data is stored | -32768 to 32767 | 16-bit signed binary | ANY16             |
| (d)     | Transfer destination device number                                                        | —               | 16-bit signed binary | ANY16             |
| EN      | Execution condition                                                                       | —               | Bit                  | BOOL              |
| ENO     | Execution result                                                                          | —               | Bit                  | BOOL              |

### Applicable devices

| ENO     | Execution result                                      | —          | Bit                    | BOOL                  |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

\*2 Data types other than INT and WORD are also available. (Except for BOOL, POINTER, and STRUCT data types (structures)). Note that available data types are INT and WORD (in range of ANY16) when "Yes" is selected for "Check the data type of instruction argument" of option settings.

For the option settings, refer to the following.

 GX Works3 Operating Manual

## Processing details

- These instructions batch-transfer the (n) points of 16-bit binary data starting from the device specified by (s) to the device specified by (d).

- Data can be transferred even when the transfer source device and destination device overlap. A transfer to smaller device numbers begins from the device specified by (s), and a transfer to larger device numbers begins from the device specified by (s)+(n)-1.
- When (s) is a word device and (d) is a bit device, the number of digit-specified bits in the word device is transferred.

### Ex.

When K1Y70 is specified in (d), the lower 4 bits of the word device specified by (s) are transferred.

- When (s) is a digit-specified bit device and (d) is a word device, the number of digit-specified bits in the word device is transferred.

### Ex.

When K1X50 is specified in (s), the data is transferred to the lower 4 bits of the word device specified by (d).

(1) Filled with 0s.

- When both (s) and (d) are bit devices, set the same number of digits for both devices.
- The link direct device, module access device, and CPU buffer memory access device cannot be specified by both (s) and (d) in one instruction. Specify any one of those for either (s) or (d).

## Operation error

| Error code (SD0) | Description                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| 3290H            | The link direct device, module access device, or CPU buffer memory access device is specified by both (s) and (d). |

# Transferring 16-bit binary data block (32 bits)

## BMOVL(P)

These instructions batch-transfer the (n) points (1 to 4294967295) of 16-bit binary data starting from the device specified.

| Ladder | ST                                              |

## Processing details

- These instructions transfer the 32-bit binary data in the device specified by (s) to the (n) points of the device specified by (d).

- When the number of digits is specified for the data in the device specified by (s), only the data corresponding to the specified digits are transferred. When K5Y40 is specified in (s), the lower 20 bits (five digits) of the word device specified by (s) are transferred.

- (1) Ignored.  
 (2) Data of 20 bits (5 digits)  
 (3) Filled with 0s.

- When the number of digits is specified for the data in the device specified by (d), the data corresponding to the specified digits are transferred. When K5Y40 is specified in (d), the lower 20 bits of the device specified by (s) are transferred. When the number of digits is specified for both data in the devices specified by (s) and (d), the data corresponding to the digits specified in (d) are transferred.

- (1) Data (20 bits (5 digits)) specified by (d)  
 (2) Data of 20 bits (5 digits)

- If (n) is 0, no processing is performed.

## Operation error

There is no operation error.

## Transferring the same 32-bit binary data block (32 bits)

### DFMOVL(P)

These instructions transfer 32-bit binary data to the (n) points (1 to 4294967295) starting from the device specified.

| Ladder | ST                                                        |

# 13 PROGRAM CONTROL

## 13.1 Program Branch Instructions

### Pointer branch

#### CJ, SCJ, JMP

- CJ: This instruction executes the program specified by the pointer number within the same program file.
- SCJ: This instruction executes the program specified by the pointer number within the same program file starting with the next scan.
- JMP: This instruction unconditionally executes the program specified by the pointer number within the same program file.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | Not supported |

| FBD/LD        |
|---------------|
| Not supported |

#### ■Execution condition

| Instruction | Execution condition                                                                 |
|-------------|-------------------------------------------------------------------------------------|

| JMP         | Every scan                                                                          |

#### Setting data

#### ■Description, range, data type

| Operand | Description                            | Range | Data type   | Data type (label) |
|---------|----------------------------------------|-------|-------------|-------------------|
| (P)     | Pointer number of the jump destination | —     | Device name | POINTER           |

#### ■Applicable devices

| Operand | Bit                              |     | Word                                  |             |   | Double word |    | Indirect specification | Constant |   |    | Others (P) |
|---------|----------------------------------|-----|---------------------------------------|-------------|---|-------------|----|------------------------|----------|---|----|------------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□\□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |            |
| (P)     | —                                | —   | —                                     | —           | — | —           | —  | —                      | —        | — | —  | ○          |

## Processing details

### ■ CJ

- This instruction executes the program specified by the pointer number within the same program file when the execution command is on.
- When the execution command is off, the program in the next step is executed.

### ■ SCJ

- This instruction executes the program specified by the pointer number within the same program file starting with the scan immediately after the execution command turns on.
- When the execution command is off or turned off, the program in the next step is executed.

### ■ JMP

This instruction unconditionally executes the program specified by the pointer number within the same program file.

## Precautions

- If the timer with its coil on is skipped by these instructions, time cannot be measured correctly.
- If the OUT instruction is skipped by these instructions, the scan time will be shortened.
- If these instructions specify and jump to the program with a bigger step number, the scan time will be shortened.
- These instructions can specify and jump to the program with a smaller step number. In this case, consider a method to exit a loop so that the watchdog timer does not time out.

- (1) While X43 is on, the loop is repeated.  
(2) To exit the loop, turn on X47.

- The value in the device skipped with these instructions remains unchanged.

When X4B turns on, the program jumps to the label, P19.  
Y43 and Y49 remain unchanged even if X4B and X4C turn on/off during the execution of the CJ instruction.

- A label (P□) occupies one step.

- (1) A label occupies one step.

- Only the pointer numbers within the same program file can be specified.

## Operation error

| Error code (SD0) | Description                                                                     |
|------------------|---------------------------------------------------------------------------------|
| 3340H            | The pointer number specified by (P) is not set before the END instruction.      |
|                  | The pointer number specified by (P) is not used as a label in the same program. |
|                  | The pointer number specified by (P) is a global pointer in another program.     |

## Jumping to END

### GOEND

This instruction jumps the program to the FEND or END instruction within the same program file.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | Not supported |

| FBD/LD        |
|---------------|
| Not supported |

### ■ Execution condition

| Instruction | Execution condition                                                               |
|-------------|-----------------------------------------------------------------------------------|
| GOEND       |  |

### Processing details

This instruction jumps the program to the FEND or END instruction within the same program file.

### Operation error

| Error code (SD0) | Description                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 3341H            | After execution of the CALL(P) or ECALL(P) instruction, the GOEND instruction is executed before the RET instruction.          |
| 3351H            | The GOEND instruction is executed before the IRET instruction in the interrupt program specified by the interrupt pointer (I). |

# 13.2 Program Execution Control Instructions

## Disabling/enabling interrupt programs

### DI, EI

- DI: This instruction disables execution of interrupt programs.
- EI: This instruction clears the interrupt disabled state.

| Ladder                                                                            | ST                           |
|-----------------------------------------------------------------------------------|------------------------------|
|  | ENO:=DI(EN);<br>ENO:=EI(EN); |

### Processing details

#### DI

- This instruction disables execution of interrupt programs until the EI instruction is executed even though they are requested.
- For the operation of the DI (Disabling interrupt programs) instruction used with the DI (Disabling interrupt programs with specified priority or lower) instruction, refer to the following.

📖 Page 542 DI

- The DI (Disabling interrupt programs) instruction cannot be executed in interrupt programs. If executed, no processing is performed.

## ■EI

- This instruction clears the interrupt disabled state that has been set by the DI (Disabling interrupt programs) instruction, and enables execution of interrupt programs with the interrupt pointer numbers permitted by the IMASK instruction. When the IMASK instruction is not executed, I32 to I43 are disabled.
- When the system is powered on or the controller is reset and moved to RUN, the system is in the state where the EI instruction has been executed. When the initial execution type program is set, the system is in the state where the DI instruction has been executed during the execution of the initial execution type program in the first scan after RUN, and where the EI instruction has been executed from the execution of the program in the second scan after RUN.
- For the operation of the EI instruction used with the DI (Disabling interrupt programs with specified priority or lower) instruction, refer to the following.

➡ Page 542 DI

A: Sequence program  
B: Interrupt program

Even if an interrupt factor occurs between the DI and EI instructions, the corresponding interrupt program will not be executed until the processing between the DI and EI instructions completes.

- The operation of the EI instruction in interrupt programs differs depending on the execution status of the DI (Disabling interrupt programs with specified priority or lower) instruction before the EI instruction. The EI instruction in the interrupt program after the execution of the DI (Disabling interrupt programs with specified priority or lower) instruction can be executed. The following table shows whether the EI instruction can be executed in the interrupt program.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

- EI and DI instructions in the initial execution type program can be executed. However, if the EI and DI instructions are executed in the initial execution type program, the specified priority setting is valid until the second scan is started. The system is in the state where the EI instruction has been executed from the time when the second scan of the program is executed.

### Point

If the interrupt disabled section is set exceeding the execution cycle of the network communication cycle synchronization interrupt, a cycle over may occur.

Either create a program by minimizing the interrupt disabled section, or exclude network communication cycle synchronization interrupts by using the DI (Disabling interrupt programs with specified priority or lower) instruction. If the DI instruction is used, interference with network communication cycle synchronization interrupts occurs, causing malfunction in the following functions.

- Motion function
- Network cycle communication function

| Error code (SD0) | Description                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3332H            | More than 16 DI (Disabling interrupt programs) instructions and DI (Disabling interrupt programs with specified priority or lower) instructions are nested. |

If the interrupt disabled section for the DI instruction is too long, the following errors or events may occur.

If an error or event occurs, either create a program by minimizing the interrupt disabled section, or exclude network communication cycle synchronization interrupts from prohibition by using the DI (Disabling interrupt programs with specified priority or lower) instruction.

| Error code/ event code | Description                                                                                                                                                                                                                                     |

## Processing details

- This instruction disables execution of interrupt programs with the interrupt pointer numbers specified by (s) or lower.

### Interrupt priority setting

| I No. | Priority |
|-------|----------|
| I50   | 29       |
| I51   | 30       |

- A: Sequence program  
B: Interrupt program  
(1) Interrupt disabled section for priority 30 or less (Interrupt enabled section for priority 29 or above)  
(2) The interrupt program can be executed because its priority is 29.  
(3) The interrupt program cannot be executed because its priority is 30.

- The execution of the EI instruction enables the interrupt that has been disabled by a single DI (Disabling interrupt programs with specified priority or lower) instruction. Note that if interrupts have been disabled only by the DI (Disabling interrupt programs) instruction, executing the EI instruction only once enables interrupts in all priorities.

A: Sequence program

- (1) Interrupt enabled section for all priorities
- (2) Interrupt disabled section for priority 30 or less (Interrupt enabled section for priority 29 or above)
- (3) Interrupt disabled section for priority 29 or less (Interrupt enabled section for priority 28 or above)
- (4) Interrupt disabled section for priority 30 or less (Interrupt enabled section for priority 29 or above)
- (5) Interrupt enabled section for all priorities
- (6) EI instruction for [DI K29]
- (7) EI instruction for [DI K30]

- When multiple DI (Disabling interrupt programs with specified priority or lower) instructions are executed and the specified interrupt disable priority is lower than the priority of the currently disabled interrupt, the priority of the currently disabled interrupt remains unchanged.
- Up to 16 DI instructions can be nested.
- The priority of the interrupt pointer can be set by parameters. (User's manual for the controller used)
- The interrupt disabled priority currently set can be checked in SD758.
- If the DI (Disabling interrupt programs with specified priority or lower) instruction is executed in the interrupt program and the interrupt disabled priority is changed, the value in SD758 also changes.

- When the DI (Disabling interrupt programs) instruction, DI (Disabling interrupt programs with specified priority or lower) instruction, and EI instruction are executed, the interrupt disabled sections will be as follows.
- When another DI (Disabling interrupt programs with specified priority or lower) instruction with a wider priority range is executed during execution of the DI (Disabling interrupt programs with specified priority or lower) instruction

A: Scan execution type program

- (1) Interrupt enabled section for all priorities
- (2) Interrupt disabled section for priority 3 or less (Interrupt enabled section for priority 2 or above)
- (3) Interrupt disabled section for priority 2 or less (Interrupt enabled section for priority 1 or above)

- When another DI (Disabling interrupt programs with specified priority or lower) instruction with a narrower priority range is executed during execution of the DI (Disabling interrupt programs with specified priority or lower) instruction

A: Scan execution type program

- (1) Interrupt enabled section for all priorities
- (2) Interrupt disabled section for priority 2 or less (Interrupt enabled section for priority 1 or above)
- (3) The priority of the disabled interrupt remains unchanged because the interrupt with priority 2 or lower is already disabled.

- When the DI (Disabling interrupt programs with specified priority or lower) instruction is executed in the interrupt program

A: Scan execution type program

B: Interrupt program

- (1) Interrupt enabled section for all priorities
- (2) Interrupt disabled section for priority 3 or less (Interrupt enabled section for priority 2 or above)
- (3) Interrupt disabled section for priority 2 or less (Interrupt enabled section for priority 1 or above)

- When only the DI (Disabling interrupt programs) instruction is executed

A: Scan execution type program

- (1) Interrupt enabled section for all priorities
- (2) Interrupt disabled section for priority 1 or less (Interrupt disabled section for all priorities)
- (3) Executing the EI instruction only once enables interrupts with all priorities.

- When the DI (Disabling interrupt programs with specified priority or lower) instruction and the DI (Disabling interrupt programs) instruction are executed in this order

A: Scan execution type program

(1) Interrupt enabled section for all priorities

(2) Interrupt disabled section for priority 2 or less (Interrupt enabled section for priority 1 or above)

(3) Interrupt disabled section for priority 1 or less (Interrupt disabled section for all priorities)

- When the DI (Disabling interrupt programs) instruction and the DI (Disabling interrupt programs with specified priority or lower) instruction are executed in this order

A: Scan execution type program

(1) Interrupt enabled section for all priorities

(2) Interrupt disabled section for priority 1 or less (Interrupt disabled section for all priorities)

- The DI instruction in the initial execution type program can be executed. However, if the DI instruction is executed in the initial execution type program, the specified priority setting is valid until the second scan is started. The system is in the state where the EI instruction has been executed from the time when the second scan of the program is executed.

## Operation error

## Processing details

- This instruction enables or disables the execution of the interrupt program with the interrupt pointer number specified by the 16 points of bit pattern starting from the device specified by (s).
  - 1 (on): Enables the execution of the interrupt program.
  - 0 (off): Disables the execution of the interrupt program.
- The interrupt pointer numbers correspond to individual bits as shown below.

|        | b15  | b14  | b13  | b12  | b11  | b10  | b9   | b8   | b7   | b6   | b5   | b4   | b3   | b2   | b1   | b0   |

- When the system is powered on or the controller is reset, the execution of interrupt programs I0 to I31 and I44 to I255 is enabled, and the execution of interrupt programs I32 to I43 is disabled.
- The states of the device range (s) to (s)+15 are stored in SD1400 to SD1415 (IMASK instruction mask pattern).

### Point

The IMASK instruction can enable or disable the execution of interrupt pointers I0 to I255 altogether. To enable or disable the execution of interrupt pointers I0 to I255, substitute the SIMASK instruction for the IMASK instruction in the program.

For details on the SIMASK instruction, refer to the following.

📖 Page 549 SIMASK

## Operation error

There is no operation error.

## Disabling/enabling the specified interrupt pointer

### SIMASK

This instruction enables or disables the execution of the interrupt program with the specified interrupt pointer number.

| Ladder | ST                   |
|--------|----------------------|
|        | ENO:=SIMASK(EN,I,s); |
| FBD/LD |                      |
|        |                      |

### ■Execution condition

### Processing details

- This instruction, according to the data specified by (s), enables or disables the execution of the interrupt program with the interrupt pointer number specified by (I).
- When (s) is 1: The execution of the interrupt program is enabled.
- When (s) is 0: The execution of the interrupt program is disabled.
- When the system is powered on or the controller is reset, the execution of interrupt programs I0 to I31 and I44 to I255 is enabled, and the execution of interrupt programs I32 to I43 is disabled.
- The execution status of the interrupt pointers is stored in SD1400 to SD1415 (IMASK instruction mask pattern).

The device (I) can be index modified. Using the SIMASK instruction specifying the index-modified device can enable or disable the execution of interrupt pointers I0 to I255.

## Operation error

| Error code<br>(SD0) | Description                                                                       |
|---------------------|-----------------------------------------------------------------------------------|
| 3285H               | The interrupt pointer number specified by (I) is out of the valid range.          |
|                     | The value in the device specified by (s) is neither 0 (disabled) nor 1 (enabled). |

## Returning from the interrupt program

### IRET

This instruction indicates the end of the processing of an interrupt program.

| Ladder                                                                            | ST            |
|-----------------------------------------------------------------------------------|---------------|
|  | Not supported |

| FBD/LD        |
|---------------|
| Not supported |

### ■ Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| IRET        | Every scan          |

### Processing details

- This instruction indicates the end of the processing of the interrupt program specified by the interrupt pointer (I).
- The instruction returns control to the sequence program after execution.

### Operation error

| Error code (SD0) | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| 3350H            | There is no pointer corresponding to the interrupt number.                                                    |
| 3351H            | After an interrupt occurs, the END, FEND, GOEND, or STOP instruction is executed before the IRET instruction. |
| 3352H            | The IRET instruction is executed before the FEND instruction in the main program.                             |
| 3353H            | The IRET instruction is executed in a fixed scan execution type program.                                      |
| 3354H            | The IRET instruction is executed in an event execution type program.                                          |

# Resetting the watchdog timer

## WDT(P)

These instructions reset the watchdog timer.

| Ladder                                                                            | ST                              |
|-----------------------------------------------------------------------------------|---------------------------------|
|  | ENO:=WDT(EN);<br>ENO:=WDTP(EN); |

## FBD/LD

### Execution condition

| Instruction | Execution condition                                                               |
|-------------|-----------------------------------------------------------------------------------|
| WDT         |  |
| WDTP        |  |

### Processing details

- These instructions reset the watchdog timer in a program.
- These instructions are used when the scan time exceeds the value set for the watchdog timer depending on the condition. If the scan time exceeds the value set for the watchdog timer every scan, change the watchdog timer value in parameter using the engineering tool.
- The time values required for t1 from step 0 to the WDT(P) instruction and t2 from the WDT(P) instruction to the END(FEND) instruction must not exceed the value set for the watchdog timer.

- The instruction can be used twice or more in a single scan, but it takes time to turn off the output when an error occurs.
- Executing the instruction does not clear the scan time value stored in the special register. For this reason, the scan time value in the special register may be greater than the value set for the watchdog timer in parameter.

### Operation error

There is no operation error.

## 13.3 Structure Creation Instructions

### Performing the FOR to NEXT instruction loop

#### FOR, NEXT

These instructions execute the processing between the FOR instruction and the NEXT instruction (n) times.

| Ladder                                                                                                     | ST            |

| (n)     | ○                                | ○    | ○                                     | ○           | ○ | —           | —  | ○                      | ○        | — | —  | — | —      |

## Processing details

- After the FOR to NEXT instruction loop is executed unconditionally (n) times, the step following the NEXT instruction is executed.
- Specify a value 1 to 32767 for (n). If a value -32768 to 0 is specified, the processing is performed regarding (n) as 1.
- To not to execute the FOR to NEXT instruction loop, use the CJ or SCJ instruction to jump the instruction loop.
- Up to 16 FOR instructions can be nested.

## Precautions

- To terminate the FOR to NEXT instruction loop being executed, use the BREAK instruction.

☞ Page 556 BREAK(P)

- To perform pulse operations of an index-modified program within the FOR to NEXT instruction loop, use the EGP or EGF instruction. Note, however, that no rising edge or falling edge instruction can be used on the operation output side.

- The JMP instruction cannot be used to branch from outside the FOR to NEXT instruction loop to inside the FOR to NEXT instruction loop, and from inside the FOR to NEXT instruction loop to outside the FOR to NEXT instruction loop, resulting in a conversion error.
- If the pointer device/label specified by the JMP instruction inside the FOR to NEXT instruction loop is index-modified, the branch cannot be executed, resulting in a conversion error.
- The CALL(P) instruction cannot be used to branch from outside the FOR to NEXT instruction loop to inside the FOR to NEXT instruction loop, resulting in a conversion error. However, if the pointer device/label specified as the branch destination in the CALL(P) instruction is index-modified and a pointer that exists in FOR to NEXT is specified after the index modification is resolved, an error (error code: 3340H) occurs when the CALL(P) instruction is executed. For details on the CALL(P) instruction, refer to the following.

☞ Page 558 CALL(P)

- For a nested structure within FOR to NEXT instruction loop, the pointer device/label specified by the JMP and other instructions can be described only if it is in the same hierarchy as the JMP and other instructions, which is the execution origin. Describing in a different hierarchy results in a convention error.

## Operation error

There is no operation error.

### Point

To create an easy-to-understand program, use a pair of instructions, the FOR and NEXT instructions, within a single program block.

# Forcibly terminating the FOR to NEXT instruction loop

## BREAK(P)

These instructions forcibly terminate the loop processing between the FOR and NEXT instructions, and pass the control to the processing of FOR to NEXT instruction or later.

| Ladder                                                                            | ST            |

## Processing details

- These instructions forcibly terminate the loop processing between the FOR and NEXT instructions, and pass the control to the processing of FOR to NEXT instruction or later.

If no BREAK instruction is executed, the program performs loop processing as many times as specified by the FOR instruction.

- (1) Forced termination condition  
(2) When the condition is met

- The remaining number of FOR to NEXT instruction loops at the time of forced termination is stored in (d). The remaining number of loops includes the processing when the BREAK(P) instruction is executed.
- The BREAK(P) instruction can be used only within the FOR to NEXT instruction loop.
- The BREAK(P) instruction is valid only for one level of nesting. To forcibly terminate multiple levels of nesting, execute as many BREAK(P) instructions as nesting levels.

### Point

When applying a program from a different series, immediately after the NEXT instruction ends, write the process to be performed when the forced termination condition written to the branch destination pointer is met.

## Operation error

There is no operation error.

# Calling a subroutine program

## CALL(P)

These instructions execute the subroutine program of the specified pointer.

| Ladder                                                                            | ST            |

\*1 Devices other than F can be used.

## Processing details

- These instructions execute the subroutine program of the pointer specified by (P). The instructions can execute the subroutine program specified by a pointer in the same program file or the subroutine program specified by a global pointer.

A: Main routine program

B: Subroutine program

- When the function device (FX, FY, or FD) is used in the subroutine program, specify the device corresponding to the function device in (s1) to (s5). The following figure shows the data of the device areas specified by (s1) to (s5).

- Before execution of the subroutine program, bit data is transferred to FX and word data is transferred to FD.
- After execution of the subroutine program, the data in FY and FD are transferred to the corresponding devices.
- The data transfer size for FX, FY, and FD differs depending on the data type specified in (s1) to (s5).

### ■When a device is specified

Function devices FX and FY are transferred in units of bits. Function device FD is transferred in units of 4 words. The size of data to be processed varies depending on the type of the device specified by an argument.

The device specified as a function device should be secured for the data size. An error occurs if an appropriate data area cannot be secured.

The following table lists the data sizes of each function device.

| Function device | Device to be used                        | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | Bit device                               | 1 bit                                                                | 1 bit                                                                |
|                 | Bit-specified word device                | 1 bit                                                                | 1 bit                                                                |
| FD              | Digit-specified bit device <sup>*1</sup> | 4 words                                                              | Digit-specified size or 4 words <sup>*2</sup>                        |
|                 | Word device                              | 4 words                                                              | 4 words                                                              |

<sup>\*1</sup> It can be specified even if the device number specified by (s1) to (s5) is not a multiple of 16 in bit device digit specification mode.

<sup>\*2</sup> If the device number is a multiple of 16 and the digit specification is K4 or K8, size of 4 words will be transferred.

#### Ex.

The following operation occurs when a device is specified.

(1) M0 is transferred to FX0.

(2) D0 to D3 are transferred to FD1.

(3) D30 to D33 are transferred to FD2.

## ■When a label is specified

When data is transferred to function devices from (s1) to (s5), function devices FX and FY are transferred in units of bits.

Function device FD is transferred in units of 4 words.

When data is transferred from function devices to (s1) to (s5), function devices FX and FY are transferred in units of bits. The unit of transfer for function device FD is the label-assigned size unit.

The following table lists the data sizes of each function device.

| Function device | Label-assigned size | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|---------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | 1 bit               | 1 bit                                                                | 1 bit                                                                |
| FD              | 2 bits or more      | 4 words* <sup>1</sup>                                                | Label-assigned size* <sup>2</sup>                                    |

\*<sup>1</sup> If the assigned size of the specified label/structure is less than 4 words, 0 is transferred for the area that is less than 4 words.

\*<sup>2</sup> If the assigned size of the specified label/structure is 4 words or more, 4 words are transferred.

### Ex.

The following table lists the label names and label types when data is transferred to function devices from (s1) to (s5).

| Label name | Label type           |
|------------|----------------------|
| bLabel1    | Bit type label       |
| uLabel1    | Word type label      |
| K3bLabel2  | Array bit type label |

(1) bLabel1 (1 bit) is transferred to FX0.

(2) uLabel1 (1 word) is transferred to FD1. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

(3) 1 word of K3bLabel2 is transferred to FD2. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- The CALL(P) instruction can use (s1) to (s5).
- The number of function devices used in the subroutine program must be identical to the number of arguments of the CALL(P) instruction. Also, the types of function devices and CALL(P) instruction arguments must be the same.
- If the timer or counter is specified as a device in the argument of the CALL(P) instruction, only the current value is transmitted/received.
- Set the device numbers in the argument of the CALL(P) instruction so that they do not overlap. If they overlap, normal operation cannot be performed.

- Do not use any device used in the argument of the CALL(P) instruction in the subroutine program. If used, normal operation cannot be performed.

**Ex.**

Incorrect operation: While D0 is specified for FD0 in the subroutine program, D1 is used in the subroutine program.

- (1) The operation result of the subroutine program is stored.
- (2) These values are replaced with the function device values.
- (3) The value of D1 is not replaced with the function device value.
- (4) Undefined values are stored.

**Ex.**

Correct operation: While D0 is specified for FD0 in the subroutine program, D4 is used in the subroutine program.

- (1) The operation result of the subroutine program is stored.
- (2) These values are replaced with the function device values.
- (3) Undefined values are stored.

- Up to 16 CALL(P) instructions can be nested. Note that the 16-level nesting is the total of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), and XCALL instructions.

- Devices which are turned on in the subroutine program hold the on state even when the subroutine program is not executed. The on state can be changed to off by executing the FCALL(P) instruction.

## Precautions

- An FBD/LD program cannot be created as a subroutine program.
- FBD/LD does not support the execution of a subroutine program with an argument.
- When the pointer specified by (P) is index-modified, an error (error code: 3340H) occurs if a pointer that exists in FOR to NEXT is specified after the index modification is resolved. If a pointer that exists in FOR to NEXT is specified directly without index modification, a conversion error occurs.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | The device specified in an argument from (s1) to (s5) cannot be secured for the data size.                                                                                                                                                               |
| 3330H            | The 17th level of the nesting is executed.                                                                                                                                                                                                               |
| 3340H            | The subroutine program corresponding to the pointer specified by (P) does not exist.<br>Alternatively, the pointer specified by (P) is index-modified, and the pointer that exists in FOR to NEXT is specified after the index modification is resolved. |
| 3341H            | After execution of the CALL(P) instruction, the END, FEND, GOEND, or STOP instruction is executed before the RET instruction.                                                                                                                            |
| 3342H            | The RET instruction is executed before the CALL(P) instruction.                                                                                                                                                                                          |

# Returning from the subroutine program called

## RET

This instruction indicates the end of a subroutine program.

| Ladder                                                                            | ST            |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| RET         | Every scan          |

### Processing details

- This instruction indicates the end of a subroutine program.
- When the instruction is executed, the program returns to the next step where the CALL(P), FCALL(P), ECALL(P), EFCALL(P), or XCALL instruction that called the subroutine program is executed.

A: Main routine program  
B: Subroutine program

### Operation error

| Error code (SD0) | Description                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3341H            | After execution of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), or XCALL instruction, the END, FEND, GOEND, or STOP instruction is executed before the RET instruction. |
| 3342H            | The RET instruction is executed before the CALL(P), FCALL(P), ECALL(P), EFCALL(P), or XCALL instruction.                                                               |

# Calling a subroutine program and turning the output off

## FCALL(P)

These instructions perform non-execution processing of the subroutine program of the specified pointer.

| Ladder                                                                            | ST            |

<sup>\*1</sup> Devices other than F can be used.

## Processing details

- When the FCALL (P) instruction is executed, this instruction executes non-execution processing<sup>\*2</sup> of the subroutine program of the pointer (P). The FCALL(P) instruction can disable the execution of the subroutine program specified by a pointer in the same program file or the subroutine program specified by a global pointer.

\*2 Non-execution processing is the same as the processing performed by each coil instruction with the condition contact set to off.

A: Main routine program

B: Subroutine program

(1) Non-execution processing is performed when the command of the FCALL(P) instruction changes from on to off.

- The operation results of individual coil instructions after the end of non-execution processing are as follows regardless of on/off of the condition contact.

| Device used for operation                                        | Operation result (device status)                                   |
|------------------------------------------------------------------|--------------------------------------------------------------------|
| High-speed timer, low-speed timer                                | Set to 0                                                           |
| High-speed retentive timer, low-speed retentive timer, counter   | Maintains the current status.                                      |
| Device in OUT instruction                                        | Forcibly turned off.                                               |
| Device in the SET, RST, SFT(P), or basic/application instruction | Maintains the current status.                                      |
| PLS or pulse instruction (□P)                                    | Performs the same processing as when the condition contact is off. |

- The FCALL(P) instruction is used in combination with the CALL(P) instruction. If the FCALL(P) instruction is not used in combination with the CALL(P) instruction, non-execution processing of the subroutine program is not performed even if the execution command is turned off, and therefore the output status of each coil instruction is retained.

- When the execution command is turned off, non-execution processing of the subroutine program is performed, enabling the OUT instruction and PLS instruction (including pulse conversion instructions) to be forcibly turned off.

**Ex.**

When the FCALL(P) instruction is used

(1) Forced off by the FCALL instruction

When the FCALL(P) instruction is not used

- When the subroutine program uses function devices (FX, FY, FD), specify the devices corresponding to the function devices in (s1) to (s5). The following figure the contents of the devices specified by (s1) to (s5).

- Before execution of the subroutine program, bit data is transferred to FX and word data is transferred to FD.
- After execution of the subroutine program, the contents of FY and FD are transferred to the corresponding devices.
- The data transfer size for FX, FY, and FD differs depending on the data type specified in (s1) to (s5).

## ■When a device is specified

Function devices FX and FY are transferred in units of bits. Function device FD is transferred in units of 4 words. The size of data to be processed varies depending on the type of the device specified by an argument.

The device specified as a function device should be secured for the data size. An error occurs if an appropriate data area cannot be secured.

The following table lists the data sizes of each function device.

| Function device | Device to be used                        | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | Bit device                               | 1 bit                                                                | 1 bit                                                                |
|                 | Bit-specified word device                | 1 bit                                                                | 1 bit                                                                |
| FD              | Digit-specified bit device <sup>*1</sup> | 4 words                                                              | Digit-specified size or 4 words <sup>*2</sup>                        |
|                 | Word device                              | 4 words                                                              | 4 words                                                              |

<sup>\*1</sup> It can be specified even if the device number specified by (s1) to (s5) is not a multiple of 16 in bit device digit specification mode.

<sup>\*2</sup> If the device number is a multiple of 16 and the digit specification is K4 or K8, size of 4 words will be transferred.

### Ex.

The following operation occurs when a device is specified.

(1) M0 is transferred to FX0.

(2) D0 to D3 are transferred to FD1.

(3) D30 to D33 are transferred to FD2.

## ■When a label is specified

When data is transferred to function devices from (s1) to (s5), function devices FX and FY are transferred in units of bits.

Function device FD is transferred in units of 4 words.

When data is transferred from function devices to (s1) to (s5), function devices FX and FY are transferred in units of bits. The unit of transfer for function device FD is the label-assigned size unit.

The following table lists the data sizes of each function device.

| Function device | Label-assigned size | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|---------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | 1 bit               | 1 bit                                                                | 1 bit                                                                |
| FD              | 2 bits or more      | 4 words <sup>*1</sup>                                                | Label-assigned size <sup>*2</sup>                                    |

<sup>\*1</sup> If the assigned size of the specified label/structure is less than 4 words, 0 is transferred for the area that is less than 4 words.

<sup>\*2</sup> If the assigned size of the specified label/structure is 4 words or more, 4 words are transferred.

**Ex.**

The following table lists the label names and label types when data is transferred to function devices from (s1) to (s5).

| Label name | Label type           |
|------------|----------------------|
| bLabel1    | Bit type label       |
| uLabel1    | Word type label      |
| bLabel2    | Array bit type label |

- (1) bLabel1 (1 bit) is transferred to FX0.
- (2) uLabel1 (1 word) is transferred to FD1. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- (3) 1 word of K3bLabel2 is transferred to FD2. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- The FCALL(P) instruction can use (s1) to (s5).
- Up to 16 FCALL(P) instructions can be nested. Note that the 16-level nesting is the total of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), and XCALL instructions.

## Precautions

- An FBD/LD program cannot be created as a subroutine program.
- FBD/LD does not support the execution of a subroutine program with an argument.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | The device specified in an argument from (s1) to (s5) cannot be secured for the data size.                                                                                                                                                                                    |
| 3330H            | The 17th level of the nesting is executed.                                                                                                                                                                                                                                    |
| 3340H            | The subroutine program corresponding to the pointer specified by the FCALL(P) instruction does not exist.<br>Alternatively, the pointer specified by (P) is index-modified, and the pointer that exists in FOR to NEXT is specified after the index modification is resolved. |
| 3341H            | After execution of the FCALL(P) instruction, the END, FEND, GOEND, or STOP instruction is executed before the RET instruction.                                                                                                                                                |
| 3342H            | The RET instruction is executed before the FCALL(P) instruction.                                                                                                                                                                                                              |

# Calling a subroutine program in the specified program file

## ECALL(P)

These instructions execute the subroutine program corresponding the specified pointer of the specified program file name.

| Ladder                 | ST            |
|------------------------|---------------|
| <p>FILE: File name</p> | Not supported |

\*1 Any value other than F can be used.

## Processing details

- When the ECALL(P) instruction is executed, these instructions execute the subroutine program corresponding to the pointer specified by (P) of the specified program file name. The ECALL(P) instructions can also call the subroutine program using the local pointer of another program file.

- Only a program file stored in program memory can be specified for the file name.
- Extension ".PRG" need not be specified for the file name. (Only .PRG files can be processed by these instructions.)
- When the subroutine program uses function devices (FX, FY, FD), specify the devices corresponding to the function devices in (s1) to (s5). The following figure the contents of the devices specified by (s1) to (s5).

- Before execution of the subroutine program, bit data is transferred to FX and word data is transferred to FD.
- After execution of the subroutine program, the contents of FY and FD are transferred to the corresponding devices.
- The data transfer size for FX, FY, and FD differs depending on the data type specified in (s1) to (s5).

## ■When a device is specified

Function devices FX and FY are transferred in units of bits. Function device FD is transferred in units of 4 words. The size of data to be processed varies depending on the type of the device specified by an argument.

The device specified as a function device should be secured for the data size. An error occurs if an appropriate data area cannot be secured.

The following table lists the data sizes of each function device.

| Function device | Device to be used                        | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | Bit device                               | 1 bit                                                                | 1 bit                                                                |
|                 | Bit-specified word device                | 1 bit                                                                | 1 bit                                                                |
| FD              | Digit-specified bit device <sup>*1</sup> | 4 words                                                              | Digit-specified size or 4 words <sup>*2</sup>                        |
|                 | Word device                              | 4 words                                                              | 4 words                                                              |

<sup>\*1</sup> It can be specified even if the device number specified by (s1) to (s5) is not a multiple of 16 in bit device digit specification mode.

<sup>\*2</sup> If the device number is a multiple of 16 and the digit specification is K4 or K8, size of 4 words will be transferred.

### Ex.

The following operation occurs when a device is specified.

(1) M0 is transferred to FX0.

(2) D0 to D3 are transferred to FD1.

(3) D30 to D33 are transferred to FD2.

## ■When a label is specified

When data is transferred to function devices from (s1) to (s5), function devices FX and FY are transferred in units of bits.

Function device FD is transferred in units of 4 words.

When data is transferred from function devices to (s1) to (s5), function devices FX and FY are transferred in units of bits. The unit of transfer for function device FD is the label-assigned size unit.

The following table lists the data sizes of each function device.

| Function device | Label-assigned size | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|---------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | 1 bit               | 1 bit                                                                | 1 bit                                                                |
| FD              | 2 bits or more      | 4 words <sup>*1</sup>                                                | Label-assigned size <sup>*2</sup>                                    |

<sup>\*1</sup> If the assigned size of the specified label/structure is less than 4 words, 0 is transferred for the area that is less than 4 words.

<sup>\*2</sup> If the assigned size of the specified label/structure is 4 words or more, 4 words are transferred.

### Ex.

The following table lists the label names and label types when data is transferred to function devices from (s1) to (s5).

| Label name | Label type           |
|------------|----------------------|
| bLabel1    | Bit type label       |
| uLabel1    | Word type label      |
| bLabel2    | Array bit type label |

(1) bLabel1 (1 bit) is transferred to FX0.

(2) uLabel1 (1 word) is transferred to FD1. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

(3) 1 word of K3bLabel2 is transferred to FD2. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- The ECALL(P) instruction can use (s1) to (s5).
- Any device used in the argument of the ECALL(P) instruction must not be used in the subroutine program. Otherwise, normal operation cannot be performed.

**Ex.**

Incorrect operation: While D0 is specified for FD0 in the subroutine program, D1 is used in the subroutine program.

- (1) The operation result of the subroutine program is stored.
- (2) These values are replaced with the function device values.
- (3) The value of D1 is not replaced with the function device value.
- (4) Undefined values are stored.

# Ex.

Correct operation: While D0 is specified for FD0 in the subroutine program, D4 is used in the subroutine program.

- (1) The operation result of the subroutine program is stored.
- (2) These values are replaced with the function device values.
- (3) Undefined values are stored.

- The device numbers specified by the ECALL(P) instruction arguments must not be overlapping. If they are overlapping, normal operation cannot be performed.
- Up to 16 ECALL(P) instructions can be nested. Note that the 16-level nesting is the total of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), and XCALL instructions.

- Devices which are turned on in the subroutine program are retained even while the subroutine program is not executed. Devices which are turned on during execution of the subroutine program can be turned off by the EFCALL(P) instruction.

## Precautions

- An FBD/LD program cannot be created as a subroutine program.
- FBD/LD does not support the execution of a subroutine program with an argument.
- When the pointer specified by (P) is index-modified, an error (error code: 3340H) occurs if a pointer that exists in FOR to NEXT is specified after the index modification is resolved. If a pointer that exists in FOR to NEXT is specified directly without index modification, a conversion error occurs.

| Error code (SD0) | Description                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2820H            | The device specified in an argument from (s1) to (s5) cannot be secured for the data size.                                                                                                                                                               |
| 2840H            | The file specified by (file name) does not exist.                                                                                                                                                                                                        |
| 2841H            | The file specified by (file name) cannot be executed.                                                                                                                                                                                                    |
| 2842H            | The type of the program with the file name specified by (file name) is not supported.                                                                                                                                                                    |
| 3330H            | The 17th level of the nesting is executed.                                                                                                                                                                                                               |
| 3340H            | The subroutine program corresponding to the pointer specified by (P) does not exist.<br>Alternatively, the pointer specified by (P) is index-modified, and the pointer that exists in FOR to NEXT is specified after the index modification is resolved. |
| 3341H            | After execution of the ECALL(P) instruction, the END, FEND, GOEND, or STOP instruction is executed before the RET instruction.                                                                                                                           |
| 3342H            | The RET instruction is executed before the ECALL(P) instruction.                                                                                                                                                                                         |

# Calling a subroutine program in the specified program file and turning the output off

## EFCALL(P)

These instructions perform non-execution processing of the subroutine program corresponding the specified pointer of the specified program file name.

| Ladder                 | ST            |
|------------------------|---------------|
| <p>FILE: File name</p> | Not supported |

| FBD/LD                 |
|------------------------|
| <p>FILE: File name</p> |

## Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| EFCALL      |                     |

\*1 Any value other than F can be used.

## Processing details

- When the EFCALL(P) instruction is executed, this instruction executes non-execution processing<sup>\*2</sup> of the subroutine program of the pointer specified by (P). The EFCALL(P) instructions can also call the subroutine program using the local pointer of another program file.

\*2 Non-execution processing is the same as the processing performed by each coil instruction with the condition contact set to off.

(1) Non-execution processing is performed when the command of the EFCALL(P) instruction changes from on to off.

- The operation results of individual coil instructions after the end of non-execution processing are as follows regardless of on/off of the condition contact.

| Device used for operation                                        | Operation result (device status)                                   |
|------------------------------------------------------------------|--------------------------------------------------------------------|
| High-speed timer, low-speed timer                                | Set to 0                                                           |
| High-speed retentive timer, low-speed retentive timer, counter   | Maintains the current status.                                      |
| Device in OUT instruction                                        | Forcibly turned off.                                               |
| Device in the SET, RST, SFT(P), or basic/application instruction | Maintains the current status.                                      |
| PLS or pulse instruction (□P)                                    | Performs the same processing as when the condition contact is off. |

- The EFCALL(P) instruction is used in combination with the ECALL(P) instruction. If the EFCALL(P) instruction is not used in combination with the ECALL(P) instruction, non-execution processing of the subroutine program is not performed even if the execution command is turned off, and therefore the output status of each coil instruction is retained.
- When the execution command is turned off, non-execution processing of the subroutine program is performed, enabling the OUT instruction and PLS instruction (including pulse conversion instructions) to be forcibly turned off.

### Ex.

When the EFCALL (P) instruction is used

(1) Forced off by the EFCALL instruction

**Ex.**

When the EFCALL (P) instruction is not used

- Only a program file stored in program memory can be specified for the file name.
- Extension ".PRG" need not be specified for the file name. (Only .PRG files can be processed by these instructions.)
- When the subroutine program uses function devices (FX, FY, FD), specify the devices corresponding to the function devices in (s1) to (s5). The following figure the contents of the devices specified by (s1) to (s5).

- Before execution of the subroutine program, bit data is transferred to FX and word data is transferred to FD.
- After execution of the subroutine program, the contents of FY and FD are transferred to the corresponding devices.
- The data transfer size for FX, FY, and FD differs depending on the data type specified in (s1) to (s5).

## ■When a device is specified

Function devices FX and FY are transferred in units of bits. Function device FD is transferred in units of 4 words. The size of data to be processed varies depending on the type of the device specified by an argument.

The device specified as a function device should be secured for the data size. An error occurs if an appropriate data area cannot be secured.

The following table lists the data sizes of each function device.

| Function device | Device to be used                        | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | Bit device                               | 1 bit                                                                | 1 bit                                                                |
|                 | Bit-specified word device                | 1 bit                                                                | 1 bit                                                                |
| FD              | Digit-specified bit device <sup>*1</sup> | 4 words                                                              | Digit-specified size or 4 words <sup>*2</sup>                        |
|                 | Word device                              | 4 words                                                              | 4 words                                                              |

<sup>\*1</sup> It can be specified even if the device number specified by (s1) to (s5) is not a multiple of 16 in bit device digit specification mode.

<sup>\*2</sup> If the device number is a multiple of 16 and the digit specification is K4 or K8, size of 4 words will be transferred.

**Ex.**

The following operation occurs when a device is specified.

- (1) M0 is transferred to FX0.  
 (2) D0 to D3 are transferred to FD1.  
 (3) D30 to D33 are transferred to FD2.

### ■When a label is specified

When data is transferred to function devices from (s1) to (s5), function devices FX and FY are transferred in units of bits.

Function device FD is transferred in units of 4 words.

When data is transferred from function devices to (s1) to (s5), function devices FX and FY are transferred in units of bits. The unit of transfer for function device FD is the label-assigned size unit.

The following table lists the data sizes of each function device.

| Function device | Label-assigned size | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|---------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | 1 bit               | 1 bit                                                                | 1 bit                                                                |
| FD              | 2 bits or more      | 4 words <sup>*1</sup>                                                | Label-assigned size <sup>*2</sup>                                    |

<sup>\*1</sup> If the assigned size of the specified label/structure is less than 4 words, 0 is transferred for the area that is less than 4 words.

<sup>\*2</sup> If the assigned size of the specified label/structure is 4 words or more, 4 words are transferred.

**Ex.**

The following table lists the label names and label types when data is transferred to function devices from (s1) to (s5).

| Label name | Label type           |
|------------|----------------------|
| bLabel1    | Bit type label       |
| uLabel1    | Word type label      |
| K3bLabel2  | Array bit type label |

- (1) bLabel1 (1 bit) is transferred to FX0.  
 (2) uLabel1 (1 word) is transferred to FD1. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- (3) 1 word of K3bLabel2 is transferred to FD2. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- The EFCALL(P) instruction can use (s1) to (s5).
- The number of function devices used in the subroutine program must be identical to the number of arguments of the EFCALL(P) instruction. Also, the types of function devices and EFCALL(P) instruction arguments must be the same.
- Up to 16 EFCALL(P) instructions can be nested. Note that the 16-level nesting is the total of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), and XCALL instructions.

## Precautions

- An FBD/LD program cannot be created as a subroutine program.
- FBD/LD does not support the execution of a subroutine program with an argument.
- When the pointer specified by (P) is index-modified, an error (error code: 3340H) occurs if a pointer that exists in FOR to NEXT is specified after the index modification is resolved. If a pointer that exists in FOR to NEXT is specified directly without index modification, a conversion error occurs.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 2840H            | The file specified by (file name) does not exist.                                                                                                                                                                                                        |
| 2841H            | The file specified by (file name) cannot be executed.                                                                                                                                                                                                    |
| 3330H            | The 17th level of the nesting is executed.                                                                                                                                                                                                               |
| 3340H            | The subroutine program corresponding to the pointer specified by (P) does not exist.<br>Alternatively, the pointer specified by (P) is index-modified, and the pointer that exists in FOR to NEXT is specified after the index modification is resolved. |
| 3341H            | After execution of the EFCALL(P) instruction, the END, FEND, GOEND, or STOP instruction is executed before the RET instruction.                                                                                                                          |
| 3342H            | The RET instruction is executed before the EFCALL(P) instruction.                                                                                                                                                                                        |

## Calling a subroutine program

### XCALL

This instruction performs execution or non-execution processing of a subroutine program. When the condition is satisfied, the instruction triggers CALL for the subroutine. When the condition turns off, the instruction triggers FCALL for the subroutine.

| Ladder                                                                            | ST            |

\*1 Devices other than F can be used.

## Processing details

- This instruction performs execution or non-execution processing of a subroutine program.
- For execution of the subroutine program, it operates each coil instruction according to the on/off status of condition contacts.
- For non-execution processing of the subroutine program, it operates each coil instruction in the same way as when condition contacts are off.
- The operation results of individual coil instructions after the end of non-execution processing are as follows regardless of on/off of the condition contact.

| Device used for operation                                        | Operation result (device status)                                   |
|------------------------------------------------------------------|--------------------------------------------------------------------|
| High-speed timer, low-speed timer                                | Set to 0                                                           |
| High-speed retentive timer, low-speed retentive timer, counter   | Maintains the current status.                                      |
| Device in OUT instruction                                        | Forcibly turned off.                                               |
| Device in the SET, RST, SFT(P), or basic/application instruction | Maintains the current status.                                      |
| PLS or pulse instruction (□P)                                    | Performs the same processing as when the condition contact is off. |

- The following figure shows the operation of the XCALL instruction.

- (1) On the rising edge of X40 (off→on): Executes the subroutine program specified by P1.
- (2) During X40 is on: Executes the subroutine program specified by P1. ("During X40 is on" does not include the rising edge of X40.)
- (3) On the falling edge of X40 (on→off): Performs non-execution processing of a subroutine program specified by P1.

- When the subroutine program uses function devices (FX, FY, FD), specify the devices corresponding to the function devices in (s1) to (s5). The following figure the contents of the devices specified by (s1) to (s5).

- Before execution of the subroutine program, bit data is transferred to FX and word data is transferred to FD.
- After execution of the subroutine program, the contents of FY and FD are transferred to the corresponding devices.
- The data transfer size for FX, FY, and FD differs depending on the data type specified in (s1) to (s5).

### ■When a device is specified

Function devices FX and FY are transferred in units of bits. Function device FD is transferred in units of 4 words. The size of data to be processed varies depending on the type of the device specified by an argument.

The device specified as a function device should be secured for the data size. An error occurs if an appropriate data area cannot be secured.

The following table lists the data sizes of each function device.

| Function device | Device to be used                        | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | Bit device                               | 1 bit                                                                | 1 bit                                                                |
|                 | Bit-specified word device                | 1 bit                                                                | 1 bit                                                                |
| FD              | Digit-specified bit device <sup>*1</sup> | 4 words                                                              | Digit-specified size or 4 words <sup>*2</sup>                        |
|                 | Word device                              | 4 words                                                              | 4 words                                                              |

<sup>\*1</sup> It can be specified even if the device number specified by (s1) to (s5) is not a multiple of 16 in bit device digit specification mode.

<sup>\*2</sup> If the device number is a multiple of 16 and the digit specification is K4 or K8, size of 4 words will be transferred.

**Ex.**

The following operation occurs when a device is specified.

- (1) M0 is transferred to FX0.  
 (2) D0 to D3 are transferred to FD1.  
 (3) D30 to D33 are transferred to FD2.

### ■When a label is specified

When data is transferred to function devices from (s1) to (s5), function devices FX and FY are transferred in units of bits. Function device FD is transferred in units of 4 words.

When data is transferred from function devices to (s1) to (s5), function devices FX and FY are transferred in units of bits. The unit of transfer for function device FD is the label-assigned size unit.

The following table lists the data sizes of each function device.

| Function device | Label-assigned size | Sizes of data when transferred to function devices from (s1) to (s5) | Sizes of data when transferred from function devices to (s1) to (s5) |
|-----------------|---------------------|----------------------------------------------------------------------|----------------------------------------------------------------------|
| FX, FY          | 1 bit               | 1 bit                                                                | 1 bit                                                                |
| FD              | 2 bits or more      | 4 words* <sup>1</sup>                                                | Label-assigned size* <sup>2</sup>                                    |

\*1 If the assigned size of the specified label/structure is less than 4 words, 0 is transferred for the area that is less than 4 words.

\*2 If the assigned size of the specified label/structure is 4 words or more, 4 words are transferred.

**Ex.**

The following table lists the label names and label types when data is transferred to function devices from (s1) to (s5).

| Label name | Label type           |
|------------|----------------------|
| bLabel1    | Bit type label       |
| uLabel1    | Word type label      |
| bLabel2    | Array bit type label |

- (1) bLabel1 (1 bit) is transferred to FX0.  
 (2) uLabel1 (1 word) is transferred to FD1. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- (3) 1 word of K3bLabel2 is transferred to FD2. Since the assigned size is less than 4 words, 0 is transferred for the area that is less than 4 words.

- The XCALL instruction can use (s1) to (s5).
- The number of function devices used in the subroutine program must be identical to the number of arguments of the XCALL instruction. Also, the types of function devices and XCALL instruction arguments must be the same.
- The device numbers specified by the XCALL instruction arguments must not be overlapping. If they are overlapping, normal operation cannot be performed.
- Up to 16 XCALL instructions can be nested. Note that the 16-level nesting is the total of the CALL(P), FCALL(P), ECALL(P), EFCALL(P), and XCALL instructions.

- Any device used in the argument of the XCALL instruction must not be used in the subroutine program. Otherwise, normal operation cannot be performed.

#### Ex.

Incorrect operation: While D0 is specified for FD0 in the subroutine program, D1 is used in the subroutine program.

- (1) The operation result of the subroutine program is stored.
- (2) These values are replaced with the function device values.
- (3) The value of D1 is not replaced with the function device value.
- (4) Undefined values are stored.

**Ex.**

Correct operation: While D0 is specified for FD0 in the subroutine program, D4 is used in the subroutine program.

- (1) The operation result of the subroutine program is stored.  
 (2) These values are replaced with the function device values.  
 (3) Undefined values are stored.

## Precautions

- An FBD/LD program cannot be created as a subroutine program.
- FBD/LD does not support the execution of a subroutine program with an argument.
- When the pointer specified by (P) is index-modified, an error (error code: 3340H) occurs if a pointer that exists in FOR to NEXT is specified after the index modification is resolved. If a pointer that exists in FOR to NEXT is specified directly without index modification, a conversion error occurs.

## Operation error

| Error code (SD0) | Description                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# 14 DATA PROCESSING

## 14.1 Rotation Instructions

### Rotating 16-bit binary data to the right

#### ROR(P), RCR(P)

- ROR(P): These instructions rotate the 16-bit binary data to the right by (n) bit(s), excluding the carry flag.
- RCR(P): These instructions rotate the 16-bit binary data to the right by (n) bit(s), including the carry flag.

| Ladder                                                                            | ST <sup>*1</sup>                                              |

## Processing details

### ■ROR(P)

- These instructions rotate the 16-bit binary data in the device specified by (d) to the right by (n) bit(s), excluding the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the ROR(P) instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 12, 3 bits are rotated because 15 divided by 12 equals 1 with a remainder of 3.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are rotated by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are rotated because 18 divided by 16 equals 1 with a remainder of 2.

## ■RCR(P)

- These instructions rotate the 16-bit binary data in the device specified by (d) to the right by (n) bit(s), including the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the RCR(P) instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 12, 3 bits are rotated because 15 divided by 12 equals 1 with a remainder of 3.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are rotated by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are rotated because 18 divided by 16 equals 1 with a remainder of 2.

## Operation error

There is no operation error.

## Rotating 16-bit binary data to the left

### ROL(P), RCL(P)

- ROL(P): These instructions rotate the 16-bit binary data to the left by (n) bit(s), excluding the carry flag.
- RCL(P): These instructions rotate the 16-bit binary data to the left by (n) bit(s), including the carry flag.

## Processing details

### ■ROL(P)

- These instructions rotate the 16-bit binary data in the device specified by (d) to the left by (n) bit(s), excluding the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the ROL(P) instruction.

- When (d) is a bit device, bits are rotated to the left within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 12, 3 bits are rotated because 15 divided by 12 equals 1 with a remainder of 3.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are rotated by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are rotated to the left because 18 divided by 16 equals 1 with a remainder of 2.

## ■RCL(P)

- These instructions rotate the 16-bit binary data in the device specified by (d) to the left by (n) bit(s), including the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the RCL(P) instruction.

- When (d) is a bit device, bits are rotated to the left within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 15 and the specified number of bits is 12, 3 bits are rotated because 15 divided by 12 equals 1 with a remainder of 3.
- Specify any value between 0 and 15 for (n). If a value 16 or bigger is specified, bits are rotated by the remainder value of  $n \div 16$ . For example, when (n) is 18, 2 bits are rotated to the left because 18 divided by 16 equals 1 with a remainder of 2.

## Processing details

### ■DROR(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the right by (n) bit(s), excluding the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the DROR(P) instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of  $n \div 32$ . For example, when (n) is 34, 2 bits are rotated because 34 divided by 32 equals 1 with a remainder of 2.

### ■DRCR(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the right by (n) bit(s), including the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the DRCR(P) instruction.

- When (d) is a bit device, bits are rotated to the right within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of  $n \div 32$ . For example, when (n) is 34, 2 bits are rotated because 34 divided by 32 equals 1 with a remainder of 2.

## Processing details

### ■DROL(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the left by (n) bit(s), excluding the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the DROL(P) instruction.

- When (d) is a bit device, bits are rotated to the left within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of  $n \div 32$ . For example, when (n) is 34, 2 bits are rotated to the left because 34 divided by 32 equals 1 with a remainder of 2.

### ■DRCL(P)

- These instructions rotate the 32-bit binary data in the device specified by (d) to the left by (n) bit(s), including the carry flag (SM700). The carry flag (SM700) is on or off depending on the status prior to the execution of the DRCL(P) instruction.

- When (d) is a bit device, bits are rotated to the left within the device range specified by digit specification. The number of bits actually to be rotated is the remainder of  $(n) \div (\text{specified number of bits})$ . For example, when (n) is 31 and the specified number of bits is 24, 7 bits are rotated because 31 divided by 24 equals 1 with a remainder of 7.
- Specify any value between 0 and 31 for (n). If a value 32 or bigger is specified, bits are rotated by the remainder value of  $n \div 32$ . For example, when (n) is 34, 2 bits are rotated to the left because 34 divided by 32 equals 1 with a remainder of 2.

## Operation error

There is no operation error.

# 14.2 Data Table Operation Instructions

## Reading the oldest data from the data table

### FIFR(P)

These instructions store the data first stored in the table in the specified device.

| Ladder | ST                                        |
|--------|-------------------------------------------|
|        | ENO:=FIFR(EN,s,d);<br>ENO:=FIFRP(EN,s,d); |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| FIFR        |                     |
| FIFRP       |                     |

### Setting data

#### Description, range, data type

| Operand | Description                                     | Range | Data type            | Data type (label)   |
|---------|-------------------------------------------------|-------|----------------------|---------------------|
| (s)     | Device for storing the data read from the table | —     | 16-bit signed binary | ANY16               |
| (d)     | Start device of table                           | —     | Word                 | ANY16 <sup>*1</sup> |
| EN      | Execution condition                             | —     | Bit                  | BOOL                |
| ENO     | Execution result                                | —     | Bit                  | BOOL                |

<sup>\*1</sup> When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

#### Applicable devices

| Operand | Bit                              |     | Word                                  |           |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|-----------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□□□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |

| (d)     | —                                | —   | ○                                     | —         | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions store the first-in data in the device specified by (d)+1 in the table specified by (d) in the device specified by (s). After execution of the FIFR(P) instruction, the data in the data table is moved forward one by one.

N: Number of data

(1) Filled with 0.

- An interlock mechanism should be used to prevent the FIFR(P) instruction from being executed when the value stored in the device specified by (d) is 0.
- A number from 0 to 65535 is stored in the number of data (d).

## Operation error

| Error code (SD0) | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 3285H            | The FIFR(P) instruction is executed when the value in the device specified by (d) is 0. |

## Reading the newest data from the data table

### FPOP(P)

These instructions store the data last stored in the table in the specified device.

| Ladder | ST                                        |
|--------|-------------------------------------------|
|        | ENO:=FPOP(EN,s,d);<br>ENO:=FPOPP(EN,s,d); |

### FBD/LD

| (d)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions store the 16-bit binary data in the device specified by (s) in the data table in the device specified by (d). The number of data stored in the table is stored in (d), and the data in the device specified by (s) is stored in order in the device specified by (d)+1 and later.

N: Number of data

D<sub>Tr</sub>: Data table range (managed by users)

- When the FIFW(P) is executed for the first time, the value in the device specified by (d) must be cleared.
- A care must be taken for the data table range because data is stored sequentially in the device specified by (d)+1 and later.
- A number from 0 to 65535 is stored in the number of data (d).

## Operation error

| Error code (SD0) | Description                                                                                 |
|------------------|---------------------------------------------------------------------------------------------|
| 3285H            | The FIFW(P) instruction is executed when the value in the device specified by (d) is FFFFH. |

# Inserting data to the data table

## FINS(P)

These instructions insert 16-bit binary data to the (n)th position in the specified data table.

| Ladder | ST                                                   |
|--------|------------------------------------------------------|

## Processing details

- These instructions delete the (n)th data in the data table in the device specified by (d) and store it in the device specified by (s). After execution of the FDEL(P) instruction, the data at the (n)+1th position and later in the data table is moved forward one by one.

N: Number of data

(1) When (n)=3, data in (d)+3 is deleted.

(2) Filled with 0.

- A number from 0 to 65535 is stored in the number of data (d).

## Operation error

| Error code (SD0) | Description                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------|
| 3285H            | The FDEL(P) instruction is executed when the value specified by (n) is 0.                                            |
|                  | The FDEL(P) instruction is executed when the value in the device specified by (d) is 0.                              |
|                  | The FDEL(P) instruction is executed when the value specified by (n) exceeds the number of data specified by (d) + 1. |

# 14.3     Reading/Writing Data Instructions

## Reading/Writing data to data memory

The data write instruction is an instruction to write arbitrary device data to data memory.  
Writing the fixed values used for operation and operation results to data memory can prevent data loss when the battery is low.  
The data that has been written to data memory can be read at any time using the data memory read instruction.

### ■Execution method

Use the SP.DEVST instruction to write device data to data memory.  
Use the S(P).DEVLD instruction to read device data from data memory to any specified device.

### ■Setting method

When the SP.DEVST and S(P).DEVLD instructions are used, a device data storage file must be set up in advance.

 [CPU Parameter] ⇒ [File Setting] ⇒ [File Setting for Device Data Storage]

| File Setting for Device Data Storage |          |
|--------------------------------------|----------|
| Use Or Not Setting                   | Use      |
| Capacity                             | 1 K Word |
| File Name                            | DEVSTORE |

| Item      | Description        |
|-----------|--------------------|
| Capacity  | 1K to 512K (words) |
| File name | DEVSTORE (fixed)   |

If data memory does not have enough free space for creating a device data storage file, an error (error code: 21A1H) occurs.  
When the controller is switched from STOP to RUN, it is checked to see whether the actual device data storage file matches the parameter setting. If they do not match, an error (error code: 21A0H) occurs.

## Reading data from the data memory

### S(P).DEVLD

These instructions read data from the device data storage file in data memory.

| Ladder | ST                                                          |
|--------|-------------------------------------------------------------|
|        | <pre>ENO:=S_DEVLD(EN,s,n,d); ENO:=SP_DEVLD(EN,s,n,d);</pre> |

| FBD/LD |
|--------|
|        |

### ■Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| S.DEVLD     |                     |
| SP.DEVLD    |                     |

### Setting data

### ■Descriptions, ranges, and data types

| Operand | Description                                                                  | Range       | Data type              | Data type (label)   |
|---------|------------------------------------------------------------------------------|-------------|------------------------|---------------------|
| (s)     | Read offset of device data storage file (specified in units of 16-bit words) | 0 to 524287 | 32-bit unsigned binary | ANY32               |
| (d)     | Device for storing the data that has been read                               | —           | Word                   | ANY16 <sup>*1</sup> |
| (n)     | Number of read points                                                        | 1 to 65535  | 16-bit unsigned binary | ANY16               |
| EN      | Execution condition                                                          | —           | Bit                    | BOOL                |
| ENO     | Execution result                                                             | —           | Bit                    | BOOL                |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

### ■Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |
|---------|----------------------------------|-----|---------------------------------------|------------|---|-------------|----|------------------------|----------|---|----|--------|
|         | X, Y, M, L, SM, F, B, SB, FX, FY | J□□ | T, ST, C, D, W, SD, SW, FD, R, ZR, RD | U□\G□, J□□ | Z | LT, LST, LC | LZ |                        | K, H     | E | \$ |        |
| (s)     | —                                | —   | ○                                     | —          | — | ○           | —  | ○                      | ○        | — | —  | —      |
| (d)     | —                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |
| (n)     | ○                                | —   | ○                                     | —          | — | —           | —  | ○                      | ○        | — | —  | —      |

## Processing details

- These instructions read device data by the number of points specified by (n) from the read offset specified by (s) in the device data storage file in data memory, and store it in the device specified by (d). (s) indicates the offset from the start of the device data storage file and can be specified by word offsets (incremented by 1 every 16 bits).

- When the S(P).DEVLD instruction is used, a device data storage file must be set up in advance. (📖 Page 608 Setting method)
- Use the SP.DEVST instruction to write device data to the device data storage file. (📖 Page 611 SP.DEVST)

## Operation error

| Error code (SD0) | Description                                           |
|------------------|-------------------------------------------------------|
| 2840H            | The device data storage file is not set in parameter. |
| 3285H            | The value specified by (n) is 0.                      |

## Writing data to the data memory

### SP.DEVST

This instruction writes the specified number of points of data to the device data storage file in data memory.

| Ladder | ST                           |
|--------|------------------------------|
|        | ENO:=SP_DEVST(EN,s1,s2,n,d); |

| FBD/LD |
|--------|
|        |

### Execution condition

| Instruction | Execution condition |
|-------------|---------------------|
| SP.DEVST    |                     |

### Setting data

### Descriptions, ranges, and data types

| Operand | Description                                                                   | Range       | Data type              | Data type (label)                       |
|---------|-------------------------------------------------------------------------------|-------------|------------------------|-----------------------------------------|
| (s1)    | Write offset of device data storage file (specified in units of 16-bit words) | 0 to 524287 | 32-bit unsigned binary | ANY32                                   |
| (s2)    | Start device to which data is to be written                                   | —           | Word                   | ANY16 <sup>*1</sup>                     |
| (n)     | Number of write points                                                        | 1 to 65535  | 16-bit unsigned binary | ANY16                                   |
| (d)     | (d): Completion device, (d)+1: Error completion device                        | —           | Bit                    | ANYBIT_ARRAY<br>(Number of elements: 2) |
| EN      | Execution condition                                                           | —           | Bit                    | BOOL                                    |
| ENO     | Execution result                                                              | —           | Bit                    | BOOL                                    |

\*1 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

### Applicable devices

| Operand | Bit                              |     | Word                                  |            |   | Double word |    | Indirect specification | Constant |   |    | Others |

| (n)     | ○                                | —   | ○                                     | —          | — | —           | —  | ○                      | ○        | — | —  | —      |
| (d)     | ○                                | —   | ○                                     | —          | — | —           | —  | ○                      | —        | — | —  | —      |

## Processing details

- These instructions retrieve the specified number of points of data specified by (n) from the device specified by (s2) and write it to the write offset in the device specified by (s1) in the device data storage file in data memory. (s1) indicates the offset from the start of the device data storage file and can be specified by word offsets (incremented by 1 every 16 bits).

- The completion device specified by (d) automatically turns on upon execution of the END instruction following the detection of processing completion of the SP.DEVST instruction and turns off upon execution of the END instruction in the next scan, so it is used as the execution complete flag of the SP.DEVST instruction.
- If the SP.DEVST instruction completes with an error, the error completion device specified by (d)+1 turns on or off at the same time as the completion device specified by (d). Therefore, the device is used as the error completion flag of the SP.DEVST instruction.
- SM753 (File being accessed) turns on while the SP.DEVST instruction is being executed. If SM753 has already been on, the SP.DEVST instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- If an error is detected during execution of the SP.DEVST instruction, the completion device (d), error completion device (d)+1, and SM753 do not turn on.
- When the SP.DEVST instruction is used, a device data storage file must be set up in advance. (📖 Page 608 Setting method)
- Use the S(P).DEVLD instruction to read device data from the device data storage file to any specified device. (📖 Page 609 S(P).DEVLD)

## Precautions

- The value written to data memory is the one at execution of the SP.DEVST instruction.
- Execution of the SP.DEVST instruction increases SD4124 and SD4125 (number of rewrite operations for built-in memory). The number of writes to the data memory of the controller is limited. If the data memory write count index exceeds 50000, an error occurs with error code 1080H.
- To prevent the data memory write count from being increased by careless instruction execution, SD771 can be set to limit the write count per day. The maximum number of writes is 36 by default. Change the maximum number of writes by using SD771 as needed. If the specified write count is exceeded, an error occurs with error code 3291H. The number of executions of the instruction to write to data memory per day is initialized to 0 at the following timing.
  - When power off→on, or when reset→reset canceled
  - The date (year, month, day) in clock data is changed by time advancement.
  - Controller internal clock data (year, month, day) is changed by the clock data change function.
- Data is written to the device data storage file when the END instruction is executed. Data is written to the device data storage file when the END instruction is executed immediately after the SP.DEVST instruction is executed. Thus, depending on the number of write points, writing to the device data storage file may involve multiple scans. Check the completion device to see whether the writing is completed.

| Error code (SD0) | Description                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------|
| 2840H            | The device data storage file is not set in parameter.                                                       |
| 3285H            | The value specified by (n) is 0.                                                                            |
| 3291H            | When the SP.DEVST instruction is executed, the write count of the day exceeds the value specified in SD771. |
|                  | When the SP.DEVST instruction is executed, a value out of the range (1 to 32767) is set in SD771.           |

# 14.4 File Operation Instructions

## Reading data from the specified file

### SP.FREAD

This instruction reads device data from the specified file in an SD memory card.

| Ladder                                                                            | ST                                  |
|-----------------------------------------------------------------------------------|-------------------------------------|

\*1 Only drive 2 (for the SD memory card) can be set.

\*2 When specifying setting data by using a label, define an array to secure enough operation area and specify an element of the array label.

\*1 When "1: Even number of bytes" or "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), the setting range of (d1)+2 (Number of read-target data) is 1 to 32767.

\*2 Even when "3: Odd number of bytes" is specified by (d1)+7 (Data type specification), specify the number in units of words. Add one byte to the odd number of bytes to be read and set the number in (d1)+2 (Number of read-target data).

## ■File name (s2)

| Device        | Item                         | Description                                                                                                  | Setting range | Set by |
| +0            | Number of data actually read | The number of data actually read is set.<br>The data unit is determined by (d1)+7 (Data type specification). | —             | System |
| +1 to +□      | Read data                    | The read data is stored.                                                                                     | —             | System |

### Processing details

- This instruction reads data from the specified file. Set the execution/completion type in the control data to specify the file read-target format.
- The read target is the data in the SD memory card only.
- The processing completion bit device (d3) automatically turns on at the execution of the END instruction in the scan in which the completion of processing of the SP.FREAD instruction is detected. The bit device (d3) turns off at the execution of the END instruction in the next scan.
- If the SP.FREAD instruction completes with an error, the error completion device (d3)+1 turns on or off in synchronization with (d3).
- SM753 (File being accessed) turns on while the SP.FREAD instruction is being executed.
- While SM753 is on, the SP.FREAD instruction cannot be executed. (If the instruction is executed, no processing is performed.)
- If an error is detected during the execution of the instruction, Processing Complete (d3), Error Completion (d3)+1, and SM753 do not turn on.
- When "Odd number of bytes" is specified by (d1)+7, the read data is stored as shown below. (In the shaded area shown below, the data before execution of the instruction is kept.)

|        | b15 | ... | b8b7 | ... | b0 |
|--------|-----|-----|------|-----|----|
| (d2)   |     |     |      |     |    |
| (d2)+1 |     |     |      |     |    |
| (d2)+2 |     |     |      |     |    |
| (d2)+3 |     |     |      |     |    |
| (d2)+4 |     |     |      |     |    |
| (d2)+5 |     |     |      |     |    |

- Specify data in (d1)+2, (d1)+4, (d1)+5, and (d2)+0 depending on the combination of (d1)+0 and (d1)+7.

## ■When reading binary data

- If the extension of the target file is omitted, the extension will be ".BIN".
- If the specified file does not exist, an error occurs.
- If the position is specified exceeding the existing file size, 0 point of data is read and the processing completes successfully.

The following figure shows an example of reading binary data.

**Ex.**

Example of reading binary data (16-bit binary data)

## ■When reading data after converted to CSV format

- Elements in the CSV format file (cells in Excel<sup>®</sup>) are read by each row and stored in the device.
- If the extension of the target file is omitted, the extension will be ".CSV".
- If the specified file does not exist, an error occurs.
- If the position is specified exceeding the existing file size, 0 point of data is read and the processing completes successfully.
- The number of data specified by (d1)+2 is read from the beginning of the file. If the last data in the file is read before reaching to the number specified, only the available number of data is read.
- When the number of columns is set to 0, the data are read by ignoring the rows in the CSV format file.
- The string data in the CSV file and the value stored in the device after it is read are determined by the execution/completion type.

| Execution/completion type        | Data (one element) in the CSV file                                                                                                                       | Value stored in the device                      | Remarks                                                                                                                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0100H: Decimal (16-bit data)     | -32768 to -1                                                                                                                                             | -32768 to -1<br>(32768 to 65535)                | The value should be within the range of -32768 to -1 as signed 16-bit data and within the range of 32768 to 65535 as unsigned 16-bit data. The same value is stored in the device.                               |
