                        |                                     |            |       |                       |                                     |            |       |                                         |         |            |      |                                           |         |            |      |                                 |     |            |      |                        |     |            |      |                                          |         |            |      |                                            |         |            |      |  |  |

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Accessible
- (3) Modem initialization  
Data communication available
- (15) Data transmission available  
Modem disconnection available
- (26) Convert the modem initialization and line connection command into pulse.
- (32) Jump to the subroutine of the modem initialization and line connection processing.
- (36) Convert the data communication (transmission) command into pulse.
- (41) Jump to the subroutine of the data reception processing.
- (45) Jump to the subroutine of the receive data.
- (49) Jump to the subroutine of the data reception processing.
- (53) Convert the line disconnection command into pulse.
- (56) Convert the connection signal OFF into pulse.
- (63) Jump to the subroutine of the line disconnection processing.
- (69) Set the initialization request signal.
- (91) Set the connection request signal.
- (93) Reset the request signal when the initialization completion signal and connection signal are turned ON.  
Read the error code when initialization/connection abnormal completion signal is turned ON, and reset the request signal.
- (108) Set the transmission channel to CH1.  
Set the send data quantity.  
Set the send data.
- (177) Transmission normal completion
- (180) Transmission abnormal completion
- (188) Set the data reception channel CH1.
- (243) Received data read normal completion
- (246) Received data read abnormal completion
- (253) Set the modem disconnection request signal.
- (255) Read the error code when modem disconnection completion signal is turned ON.  
Set the modem disconnection completion flag when normal completion signal is turned ON.
- (264) Reset the modem disconnection request signal.

## Connection receiving station side (RJ71C24-R2②) program example

Perform data communication using the nonprocedural protocol by the command from the user after the 'Connection' (X12) turns ON.

### ■Parameter list

| Category             | Setting item                                       |                                |                                         | Setting content          |
|----------------------|----------------------------------------------------|--------------------------------|-----------------------------------------|--------------------------|
| Basic settings       | Communication protocol setting                     |                                |                                         | Nonprocedural protocol   |

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Reads the received data.              | —          |                       |            |           |       |                       |   |                   |     |            |     |   |                     |     |            |    |   |                           |     |            |     |   |                        |     |            |     |   |              |     |            |     |   |                                    |     |            |      |   |                                      |     |            |      |   |                                   |     |            |      |   |                    |     |            |      |    |                                   |     |            |      |    |                                     |     |            |      |    |                                  |     |            |      |    |                                     |                     |            |     |    |                               |                     |            |     |    |                                       |                                     |            |      |    |                                         |                                     |            |      |    |                             |                                     |            |      |    |                                 |                                     |            |      |    |                                 |                                     |            |      |    |                            |                                     |            |      |    |                                    |                                     |            |      |    |                                         |         |            |     |    |                                           |         |            |     |    |                                        |         |            |     |    |                                          |         |            |     |    |                                 |     |            |    |    |                             |     |            |    |    |                          |                                     |            |      |    |              |     |            |      |    |                                  |         |            |      |    |                                    |         |            |     |    |                   |                                     |            |      |

For information on the module FB to be used, refer to the following manual.

# 10 RECEIVING DATA WITH AN INTERRUPT PROGRAM

10

In data communications between C24 and a target device, an interrupt program can be used to receive data for the following data communication functions.

- Data reception during communication using the nonprocedural protocol
- Data reception during communication using the bidirectional protocol

This chapter explains data reception with the following data communication function by an interrupt program.

## Point

Receiving data with an interrupt program expedites the process of retrieving received data to the CPU module.

## 10.1 Settings for Receiving Data Using an Interrupt Program

The following explains the settings for performing data reception with an interrupt program during communication using the nonprocedural protocol or bidirectional protocol.

For setting for data reception with an interrupt program, set "Interrupt factor" to "BUFRCVS instruction data reception", and set the interrupt pointer to be used in the program to "Interrupt pointer".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ Module Name ⇒ [Module Parameter] ⇒ "Interrupt Settings"

## 10.2 Interrupt Program Startup Timing

The following explains the startup timing for interrupt program when performing data reception with an interrupt program during communication using the nonprocedural protocol or bidirectional protocol.

- The startup timing is the same for communication using either the nonprocedural protocol or bidirectional protocol.
- Received data from the target device is stored in the receive area of the buffer memory. When the next input signal rises, the interrupt program is started.

| Input signal name                       | CH1 side | CH2 side |
|-----------------------------------------|----------|----------|
| CHn reception data read request signal  | X3       | XA       |
| CHn reception abnormal detection signal | X4       | XB       |

## 10.3 Reception Control Method Using an Interrupt Program

The following explains the reception control method when receiving data with an interrupt program during communication using the nonprocedural protocol or bidirectional protocol.

- ❶ When data is received from the target device, the receive data is stored in the buffer memory and the 'CH1 reception data read request' signal turns ON.
- ❷ The main program stops executing and the interrupt program starts.
- ❸ The data reception dedicated instruction, BUFRCVS, for the interrupt program is executed and data is received.\*1
- ❹ When the execution of the BUFRCVS instruction is complete, the 'CH1 reception data read request' signal turns OFF.
- ❺ The execution of the interrupt program is completed, and execution of the main program restarts.

\*1 When the reading of received data using the BUFRCVS instruction is finished, the following processes are performed.

- At normal completion  
CPU module error flag (SM0) turns OFF.
- At abnormal completion  
CPU module error flag (SM0) turns ON.

The error code is stored in the CPU module error code (SD0).

For more details on the error flag (SM0) and error codes (SD0) of the CPU module, refer to the following manual.

# 10.4 Program Example

This section shows programming examples for data reception with an interrupt program in data communications using the nonprocedural protocol or bidirectional protocol.

10

## Program example for data reception

The following shows a program example for data reception with an interrupt program in data communication using the nonprocedural protocol.

### Parameter list

The following shows the parameters for this program.

| Setting item       |     |                   | Setting content                    |
|--------------------|-----|-------------------|------------------------------------|
| Interrupt settings | CH1 | Interrupt factor  | BUFRCVS instruction data reception |
|                    |     | Interrupt pointer | I50                                |

### Program example

| Category            | Label name                                     | Description                              | Device                      |
|---------------------|------------------------------------------------|------------------------------------------|-----------------------------|
| Module label        | C24_1.stnCH1.bSet_Req_ReceptionRead_D          | CH1 Reception data read request          | DX3                         |
|                     | C24_1.stnCH1.bSts_ReceptionAbnormalDetection_D | CH1 Reception abnormal detection         | DX4                         |
|                     | C24_1.stnCH1.uSet_ReceiveInterruptIssued_D     | CH1_Receive interrupt-issued designation | U0\G8208                    |
| Label to be defined | Define the global label as shown below.        |                                          |                             |
|                     | Label Name                                     | Data Type                                | Class Assign (Device/Label) |
| 1                   | bNormalReceptionFlag                           | Bit                                      | VAR_GLOBAL M100             |
| 2                   | bAbnormalReceptionFlag                         | Bit                                      | VAR_GLOBAL M101             |
| 3                   | wReceiveDataLength                             | Word [Unsigned]/Bit String [16-bit]      | VAR_GLOBAL D200             |

(0) For the CH1 side, designate the receive interrupt-issued designation.

(15) Receive the data.

### Point

- For communication using either the nonprocedural protocol or bidirectional protocol, BUFRCVS instruction is used to receive data with an interrupt program. (☞ Page 580 Dedicated Instructions)
- To startup an interrupt program, create a program to allow/prohibit interrupt during the main program. Instruction to be used is EI, DI, and IMASK.

# 10.5 Considerations when Receiving Data with an Interrupt Program

This section describes the considerations when receiving data with an interrupt program.

- Create an interrupt program for data reception for each interface.
- Do not use the INPUT and BIDIN instructions during execution of the interrupt program.  
Always use the BUFRCVS instruction to receive data.
- Do not turn the 'CH□ reception data read completion' (Y1/Y8) ON/OFF during execution of the interrupt program since C24 turns OFF the 'CH□ reception data read request' (X3/XA) and the 'CH□ reception abnormal detection' (X4/XB) for data reception with an interrupt program.
- Use always ON (SM400) or direct input signal (DX3, DX4) as the contact signal when executing the BUFRCVS instruction.
- After the power supply turns OFF → ON or the CPU module is reset, data cannot be received because the interrupt program is invalid during the initial processing of the CPU module. For asynchronous data communication with C24 from the target device without communication procedure setting, refer to the program example shown below.

## Program example

The following shows an example of program for asynchronous data communications from the target device side to C24 without communication procedure settings on the target device side.

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Description                                | Device   |            |                       |           |  |       |                       |   |                                          |     |     |            |    |   |                                         |     |     |            |    |   |                                        |     |     |            |    |   |                                |     |     |            |     |   |                 |                                     |     |            |    |   |                             |                                     |     |            |    |   |                |                                     |     |            |    |   |                    |                                     |     |            |    |   |                               |                                            |     |            |     |    |                                 |                                            |     |            |      |    |                                     |               |     |            |    |    |                                       |               |     |            |    |

For information on the module FB to be used, refer to the following manual.

 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) For the CH1 side, designate the receive interrupt-issued designation.
- (61) Processing at normal completion
- (65) Processing at abnormal completion
- (71) Execute the receive interrupt program.

# 11 CHANGING DATA LENGTH UNITS TO BYTE UNITS (WORD/BYTE UNITS SETTING)

The word units are used for the data length (count) of the amount of data transmitted/received using the following data communication functions in data communication between C24 and target devices.

This chapter explains how to change the units (word → byte, byte → word) of the data length (count) transmitted/received with the following data communication functions.

The data length units can be set for each C24 interface. C24 controls the number of data to be transmitted to the target device and the number of data when it requests the CPU module to read the data received from the target device according to the units set by the user.

## Data communication functions and buffer memory affected by data length units

The following lists the data communication functions and buffer memory which are affected by the data length units. (The buffer memory addresses in the table are the default value.)

| Data communication function |                            | Name of buffer memory related to data length units                                                                                        | Reference                                                           |

## How to change the units of the data length (count)

Change the units of the data length (count) by the either of the following methods.

- Changing with Engineering tool  
Set "Word/byte units designation" to "Byte units".
- Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"
- Changing by the CPU module  
The units can be changed with the CSET instruction. (Page 580 Dedicated Instructions)

# 12 CHANGING DATA COMMUNICATION MONITORING TIME

The monitoring time is time used by C24 to monitor the receiving interval time between each byte when receiving data from the target device, the programmable controller CPU processing time, and the time it takes to transmit to the target device. The monitoring time can be set for each interface. C24 uses the monitoring time set by the user to control data transmission to and reception from the target device.

Set the monitoring time in accordance with the specifications of the target device.

C24 monitoring times are listed below.

○: Configurable ×: Non-configurable, —: Not used

| Monitoring time                        |                        | C24 default value           | Protocol that can monitor the time |     |    |    | Remarks                                                                            |
|----------------------------------------|------------------------|-----------------------------|------------------------------------|-----|----|----|------------------------------------------------------------------------------------|
|                                        |                        |                             | MC                                 | Non | Bi | Pd |                                                                                    |
| No-reception monitoring time (timer 0) | Method 0 <sup>*1</sup> | 0 bytes<br>(Unlimited wait) | ○                                  | ○   | ○  | —  | Transmission time for the set number of byte (depending on the transmission speed) |
|                                        | Method 1 <sup>*1</sup> |                             | ×                                  | ○   | ×  | —  |                                                                                    |
| Response monitoring time (timer 1)     |                        | 5 seconds                   | ○                                  | —   | ○  | ○  | Transmission only for the bidirectional protocol.                                  |

| Transmission wait time                 |                        | 0 ms                        | ○                                  | —   | —  | —  | No wait time                                                                       |

\*1 Nonprocedural and no-reception monitoring time method

The C24 input signal which turns ON when the no-reception monitoring time (timer 0) timed out differs.

| Nonprocedural and no-reception monitoring time method | Input signal which turns ON           |
|-------------------------------------------------------|---------------------------------------|
| Method 0                                              | Reception abnormal detection (X4, XB) |
| Method 1                                              | Reception data read request (X3, XA)  |

Ex.

Data communication using MC protocol

# 12.1 No-reception Monitoring Time (timer 0) Setting

The no-reception monitoring time (timer 0) is a monitoring time for clearing the state of C24 when it is placed into the data receive wait state by trouble on the target device side.

C24 monitors the reception interval in byte units at the start of data reception from the target device and ends monitoring when the preset last data is received, and it repeats this operation.

The following explains the no-reception monitoring time (timer 0) operation.

One byte is always handled as 12 bits in the no-reception monitoring time (timer 0), regardless of the transmission setting.

When the no-reception monitoring time (timer 0) is changed by a program, perform any of the following to enable the changed value.

- Mode switching (  Page 409 SWITCHING THE MODE AFTER STARTING)
- UINI instruction (  MELSEC iQ-R Programming Manual (Module Dedicated Instructions))
- Programmable controller CPU information clear (  Page 498 How to Clear Programmable Controller CPU Information)

## C24 operation by no reception monitoring time (timer 0)

C24 monitors the reception interval in byte units and returns the elapsed time to 0 each time one byte is received.

At time-out, C24 performs the following processing.

### Data communication using the MC protocol

- C24 stores the error code to the 'MC protocol send error code' (Un\G602/618) for the target interface side.
- C24 transmits a NAK message to the target device and waits to receive the next command message.

### Data communications using the nonprocedural protocol (Method 0)

#### ■Data communications not using user frames

- C24 retrieves the received data up to time-out to C24.
- C24 stores the error code to the 'Data reception result' (Un\G600/616) for the target interface and turns ON the 'CH□ reception abnormal detection' (X4, XB), and waits to receive the next data.

#### Ex.

Receiving by the receive end code (Receive end code: CR + LF (0D0AH))

When the LF is not received within the set time for timer 0 after reception of the CR, the received data up to the CR is stored in the receive data storage area of the buffer memory and the reception abnormal detection signal to the CPU module turns ON.

\*1 CR is treated as 1 byte of data included in the message.

## ■Data communications using user frames

- When designating the final frame, C24 retrieves an arbitrary portion of data in the received data between the start of the reception of the current message and the time-out, and ignores (deletes) the data in the final frame portion.
- C24 stores the error code to the 'Data reception result' (Un\G600/616) for the target interface and turns ON the 'CH□ reception abnormal detection' (X4, XB) and waits to receive the next data.

## Data communication using the nonprocedural protocol (Method 1)

The reception monitoring using Method 1 of the no-reception monitoring time (timer 0) is used to receive a message of which receive end code and receive end data quantity are not determined due to time-out of the no-reception monitoring time (timer 0) in data communication using the nonprocedural protocol.

- Data is received by C24 until the time is out, the 'CH□ reception data read request' (X3, XA) turns ON, and waits to receive the next data.

### Ex.

When receiving using the receive end data quantity (Receive end data quantity: 511 bytes)

After 16 bytes of data is received, the 16-byte data is stored in the receive data storage area of the buffer memory by the time out (timer 0) and the reception data read request signal to the CPU module turns ON.

## Data communications using the bidirectional protocol

- C24 ignores (deletes) the received data from the start of reception of the current message to time-out.
- C24 stores the error code to the 'Data reception result' (Un\G600/616) for the target interface.
- When reading received data is completed, C24 transmits a NAK message to the target device, and waits to receive the next data.

## Changing the no-reception monitoring time (timer 0)

### Changing the no-reception monitoring time (timer 0)

For the no-reception monitoring time (timer 0), set the number of transmission characters (number of bytes) corresponding to the data transmission speed set to the target interface to "No-reception monitoring time (timer 0) designation".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

Adjust or set the value based on the specifications of the target device.

### Nonprocedural no-reception monitoring time method designation (Method 0/1)

For the nonprocedural and no-reception monitoring time method designation, set the method to use the no-reception monitoring time (timer 0) in data communications using the nonprocedural protocol to "Nonprocedural and no-reception monitoring time method designation".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

## Remarks

### ■When changing the no-reception monitoring time (timer 0)

Set the no-reception monitoring time (timer 0) to the following number of bytes or greater.

$$\text{No-reception monitoring time (timer 0)} = 1 + \frac{T_d \times V_{\text{bps}}}{12000}$$

(Round up fractions below decimal point.)

$T_d$  : Maximum delay time for target device output processing (ms)

$V_{\text{bps}}$ : Transmission rate (bps)

**Ex.**

Calculation of no-reception monitoring time (timer 0)

Transmission rate ( $V_{\text{bps}}$ ) : 9600 bps

Maximum delay time for target device output processing ( $T_d$ ) : 50 ms

$$\text{No-reception monitoring time (timer 0)} = 1 + \frac{50 \times 9600}{12000} = 41 \text{ bytes}$$

In this case, actual monitoring time is as shown below:

$$41 \text{ bytes} \times 12^{*1} \div 9600 \times 1000 = 51.25 \text{ ms}$$

\*1 Number of transmit bits per byte (Fixed)

### ■When changing the no-reception monitoring time (timer 0) for data communication with a target device through C24 RS-422/485 interface

Set the no-reception monitoring time (timer 0) to the following number of bytes or greater.

$$\text{No-reception monitoring time (timer 0)} = 1 + \frac{(T_d + T_1) \times V_{\text{bps}}}{12000}$$

(Round up fractions below decimal point.)

$T_d$  : Maximum delay time for target device output processing (ms)

$T_1$  : Target device side hardware gate OFF time (ms)

$V_{\text{bps}}$ : Transmission rate (bps)

## 12.2 Response Monitoring Time (timer 1) Setting

The response monitoring time (timer 1) is a monitoring time for clearing the receive wait state of the device that receives a response message when any trouble occurs on the side of device which received a message and the response message (result) cannot be returned to the target device.

When C24 receives a message from the target device, it monitors the CPU module processing time up to the start of transmission of the response message to the target device.

When a message was transmitted, it monitors the target device processing time up to the start of reception of the response message from the target device.

The following describes the response monitoring time (timer 1) operation.

If on-demand data is transmitted before a response message during data communications using the MC protocol, the time up to the start of transmission of the on-demand data is monitored.

### C24 operation by response monitoring time (timer 1)

#### When response monitoring time (timer 1) is set to 0 ms

- After receiving a message, C24 does not monitor the time up to the start of transmission of the response message to the target device, but waits infinitely.
- After transmitting a message, C24 does not monitor the time up to the start of reception of the response message from the target device, but waits infinitely.

#### When response monitoring time (timer 1) is set to 100 ms or longer

- After receiving a message, C24 monitors the time up to the start of transmission of the response message to the target device and returns the elapsed time to 0 at the start of transmission.
- After transmitting a message, C24 monitors the time up to the start of reception of the response message from the target device and returns the elapsed time to 0 at the start of reception.

At time-out, C24 performs the following processing.

#### ■Data communications using the MC protocol

- C24 stores the error code to the 'MC protocol send error code' (Un\G602/618) for the target interface.
- C24 transmits a response message (NAK message) to the target device and waits to receive the next command message.

#### ■Data communications using the bidirectional protocol

- C24 stores the error code to the 'Data transmission result' (Un\G599/615) for the target interface and completes the transmission processing abnormally.
- While waiting to transmit a response message, C24 does not check the response monitoring time.

## Changing the response monitoring time (timer 1)

The response monitoring time (timer 1) is registered on "Response monitoring time (timer 1) designation" of the parameter.

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings"  
⇒ "Various control specification"

During data communications using the MC protocol, set the response monitoring time so as to be as long as the transmission wait time or longer.

The transmission wait time is designated in the following:

- 1C frame: Designate it is a command message.
- 2C/3C/4C frame: "Transmission wait time designation"

### Considerations for data communications using the MC protocol

When changing the response monitoring time (timer 1) default value (5 sec), take into account the following.

Set it as to be as long as the transmission wait time or longer in either case of the following. ( Page 267 Transmission Wait Time Setting)

#### ■When specifying monitor condition

When designating the monitor conditions with the following functions, set the maximum time according to the system operation.

- Random read in word units
- Device memory monitor

#### ■When accessing by other than above

- When accessing a station connected (including multidrop connection) to a target device, set the following value, or longer.  
Response monitoring time  $\geq$  Maximum number of scans required to process the command used  $\times$  Connected station scan time
- When accessing another station over a network system, set the default value to 'Unlimited wait', or the following time or longer.

Response monitoring time  $\geq$  maximum number of scans required to process the command used  $\times$  communications time

When setting the default value to 'Unlimited wait', check the target device response wait time, and initialize C24 transmission sequence when time-out occurs.

For the maximum number of scans and the communication time required by processing, refer to the following manual.

 MELSEC Communication Protocol Reference Manual

### Considerations for data communications using bidirectional protocol

when changing the default value (5 seconds) for the response monitoring time (timer 1), set it as to be as long as the following time, or longer.

- (Sequence scan time  $\times$  2) + 100 ms

## 12.3 Send Monitoring Time (timer 2) Setting

The send monitoring time (timer 2) is a monitoring time for clearing the wait state of C24 when C24, which is to transmit a message or response message (result), is placed into the data transmit wait state due to any trouble of the target device side. When C24 transmits a message, it monitors the wait time up to the end of transmission of the message.

When C24 received a message from a target device, it monitors the wait time up to the end of transmission of the response message.

The following explains the send monitoring time (timer 2) operation.

If on-demand data is transmitted before a response message during data communications using the MC protocol, each time is monitored.

### C24 operation by send monitoring time (timer 2)

#### When send monitoring time (timer 2) is set to 0 ms

- The time until transmission of a message or response message has been completed is not monitored.
- If C24 cannot transmit, it waits infinitely.

#### When send monitoring time (timer 2) is set to 100 ms or longer

- C24 monitors the time from completion of message or response message transmission preparations to the end of transmission, and returns the elapsed time to 0 at the end of transmission.

At time-out, C24 performs the following processing.

#### ■Data communications using MC protocol

- While waiting for the end of transmission of the response message, C24 stores the error code to the 'Data transmission result' (Un\G599/615) for the target interface.  
C24 enters the state in which it waits to receive the next command message without sending a response message (NAK message) to the target device.
- During on-demand data transmission, C24 stores the error code to the 'On-demand execution results' (Un\G598/614) for the target interface.
- If transmission was terminated midway in either of the cases above, C24 does not transmit the remaining data.

## ■Data communications using nonprocedural protocol or bidirectional protocol

- While waiting for the end of transmission of a message, C24 stores the error code to the 'Data transmission result' (Un\G599/615) for the target interface and completes the transmission processing abnormally.  
If message transmission was terminated midway, C24 does not transmit the remaining data.
  - If waiting for the end of transmission of a response message, C24 stores the error code to the 'Data reception result' (Un\G600/616) for the target device and turns ON the 'CH□ reception abnormal detection' (X4, XB).<sup>\*1</sup>  
When the receive data read processing completes, C24 turns OFF the 'CH□ reception abnormal detection' (X4, XB) and waits to receive the next command.  
If transmission of the response message was terminated midway, C24 does not transmit the remaining data.
- <sup>\*1</sup> When communicating using bidirectional protocol, it stores the error code in the data reception result storage area for the target interface. (The reception abnormal detection signal does not turn ON.)

## Changing the send monitoring time (timer 2)

The send monitoring time (timer 2) is set in "Send monitoring time (timer 2) designation" of the parameter.

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings"  
⇒ "Various control specification"

The send monitoring time (timer 2) monitors the transmission termination time in the condition below.

- When DTR/DSR signal control is used and the DR (DSR) signal is turned OFF ( Page 269 Control Contents of DTR/DSR (ER/DR) Signal Control)
- When DC1/DC3 receive control is used and DC3 is received ( Page 271 Control Contents of DC Code Control)
- When the RS-232 interface CS (CTS) signal is turned OFF ( MELSEC iQ-R Serial Communication Module User's Manual(Startup))

### Remarks

#### ■When changing the send monitoring time (time 2) setting

Find the send monitoring time (timer 2) from the maximum delay time for the message reception processing or response message transmission processing on the target device side and the transmission time per one-byte (t), and change the setting value. However, the value should be rounded to the nearest 100 ms above.

- Number of bytes transmitted per second (n) = Transmission rate/number of bits transmitted per byte
- Transmission time per byte (t) = 1000 (ms)/number of bytes transmitted per second (n)
- Send monitoring time (timer 2) = (Maximum processing delay time of target device) + (Transmission time per one-byte (t) × Number of transmission bytes)

Under the following conditions, the send monitoring time (timer 2) is set to 300 ms.

- Transmission rate : 9600 bps
- Number of transmit bits/byte : 11 (start bit: 1, data bits: 8, stop bits: 2)
- Maximum processing delay time : 200 ms
- Number of transmission bytes: 3 bytes

## 12.4 Transmission Wait Time Setting

The transmission wait time is used during data communications using the MC protocol.

It is the time for a target device that cannot receive the data immediately after data has been transmitted.

When C24 transmits a response message in reply to a command message received from the target device, transmission of the response message is delayed by the transmission wait time, or longer.

The following explains the transmission wait time operation for data communications using 2C/3C/4C frame. (For 1C frame, the transmission wait time is designated in the command message.)

### C24 operation by transmission wait time

#### When transmission wait time is set to 0 ms

If a response message can be transmitted, C24 immediately transmits the response message. A transmission wait time is not set.

#### When the transmission wait time is set to 10 ms or longer

If a response message can be transmitted, and the transmission wait time after reception of the command message has elapsed, C24 transmits the response message.

### Changing the transmission wait time

The transmission wait time is registered on "Transmission wait time designation" of the parameter.

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

- If the target device that must wait a certain time before it can receive a response message after a command message was transmitted, set the transmission wait time as explained above.  
Especially, for data communications with a target device connected to C24 RS-422/485 interface, set the transmission wait time to the hardware gate OFF time or longer of the target device.
- The transmission wait time described here is the time for data communications using the 2C/3C/4C frame.

# 13 DATA COMMUNICATIONS USING DC CODE TRANSMISSION CONTROL

The transmission control function controls (suspends, restarts) the transmission and reception of data between C24 and target device by turning transmission control signals ON and OFF or by transmitting and receiving DC codes (DC1, DC2, DC3, DC4), or informs the valid range for the data to the target device.

The transmission control function can be set for each C24 interface. C24 uses the transmission control function set by the user to control data communications with target devices.

Set the transmission control function to match the specifications of the target device.

The table below lists C24 transmission control functions.

The meanings of abbreviations in the table are as follows:

- MC: MC protocol
- Non: Nonprocedural protocol
- Bi: Bidirectional protocol
- Pd: Predefined protocol
- MD: MODBUS (slave function)
- S: Simple CPU communication

(○: Valid, —: Invalid)

| Transmission control function        | Type of control              | Interface that can be controlled |          | Protocol that can be controlled |     |    |    |    |   | Remarks                                                                                                            |
|--------------------------------------|------------------------------|----------------------------------|----------|---------------------------------|-----|----|----|----|---|--------------------------------------------------------------------------------------------------------------------|
|                                      |                              | 232                              | 422/485  | MC                              | Non | Bi | Pd | MD | S |                                                                                                                    |
| DTR/DSR signal control <sup>*1</sup> | DTR control                  | ○                                | —        | —                               | ○   | —  | ○  | —  | ○ | Cannot be used simultaneously with DC control. Select either one.                                                  |
|                                      | DSR control                  |                                  | (ignore) | ○                               | ○   | —  | ○  | —  | ○ |                                                                                                                    |
| RS/CS signal control <sup>*2</sup>   |                              | ○                                | —        | ○                               | ○   | ○  | ○  | ○  | ○ | Normally controlled.                                                                                               |
| CD signal control <sup>*2</sup>      |                              | ○                                | —        | ○                               | ○   | ○  | ○  | —  | ○ | The cable wiring depends on whether or not control is used. With half-duplex communications, control is necessary. |
| DC code control <sup>*1</sup>        | DC1/DC3 transmission control | ○                                | ○        | —                               | ○   | —  | ○  | —  | ○ | Cannot be used simultaneously with DTR/DSR signal control. Select either one.                                      |
|                                      | DC1/DC3 reception control    |                                  |          | ○                               | ○   | ○  | ○  | —  | ○ |                                                                                                                    |
|                                      | DC2/DC4 transmission control |                                  |          | ○                               | ○   | ○  | ○  | —  | ○ |                                                                                                                    |
|                                      | DC2/DC4 reception control    |                                  |          | ○                               | ○   | ○  | ○  | —  | ○ |                                                                                                                    |

\*1 Refer to the following section when the full-duplex communication is used to communicate data with the bidirectional protocol.

☞ Page 107 Processing when Simultaneous Transmission is Performed during Full-Duplex Communications

\*2 Check the operation on C24 by the RS(RTS) signal, control contents of CS(CTS) signal, or CD terminal check designation.

📖 MELSEC iQ-R Serial Communication Module User's Manual(Startup)

## Precautions

- When C24 is started, DTR/DSR signal control and RS/CS signal control are enabled.
- For simple CPU communication, a setting for communication depends on the target device. Set it according to the target device. (☞ Page 121 Data Communication Procedure)

## How to change the transmission control method and DC code

Switching between DC code control and DTR/DSR control as well as changing of the DC code are set on "Transmission control specification" of the parameter.

🔍 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

# 13.1 Control Contents of DTR/DSR (ER/DR) Signal Control

This control uses the RS-232 interface DTR/DSR signals to inform the target device whether or not the host station is ready to receive data.

C24 uses the ER (DTR) signal to inform the target device whether or not the host station is ready to receive data, and uses the DR (DSR) signal to check if the target device is ready to receive data.

Ex.

## C24 DTR control contents and free OS area specification

### C24 DTR control contents

C24 uses the ER (DTR) signal to inform the target device whether or not it is ready to receive data.

The data transmitted from the target device using the nonprocedural protocol is stored in the receive data storage area in the buffer memory through the OS area. (Page 57 Receiving Data from Target Device)

Under the following conditions, received data is temporarily stored in the OS area and is transferred to the receive data storage area when the current received data read processing is completed.

- Received data exceeding the size of the receive data storage area on the buffer memory when data, which is "receive data storage area < receive data length", was received.
- Data received before the program reads the previously received data.

C24 turns the ER (DTR) signal ON/OFF as listed below, depending on the size of the free OS area.

- Free area is 64 bytes (default) or less: OFF
- Free area is 263 bytes (default) or more: ON

## Free OS area specification

For the DTR/DSR (ER/DR) signal control, an available capacity in the OS area that informs data cannot be received can be set in the parameter below.

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings"  
⇒ "Various control specification"

Set the setting value as to be "Transmission control start free space < Transmission control end free space".

- "Transmission control start free space designation"

Specify an available capacity in the OS area in order to notify that data cannot be received (ER (DTR) signal is OFF).

- Transmission control start free space: 64 to 4,095 (Default: 64)

- "Transmission control end free space designation"

Specify an available capacity in the OS area in order to notify that data can be received (ER (DTR) signal is ON).

- Transmission control end free space: 263 to 4,096 (Default: 263)

### ■Remarks

- The receive data clear processing clears the data stored in the OS area. (The receive area in the buffer memory is not cleared.) ( Page 70 Receive data clear)
- If more data is received when the above free OS area is 0 bytes, an SIO error occurs and the received data is ignored until a free area is available. In this case, the SIO signal turns ON. ( Page 511 Hardware information communication error "SIO" occurs)

## C24 DSR control

C24 uses the DSR signal to detect whether or not the target device is ready to receive data and to control data transmission to the target device as shown below, depending on whether the DSR is ON/OFF.

- If the DSR signal is ON and there is data to be transmitted, C24 transmits it to the target device.
- If the DSR signal is OFF, even if there is data to be transmitted, C24 does not transmit it to the target device.

When the DSR signal is turned ON, C24 transmits the data to the target device.

## 13.2 Control Contents of DC Code Control

This control uses C24 transmission control data to inform a target device whether or not host station is ready to receive data and the valid range of the transmitted/received data.

The four types of C24 DC code control shown below are available. These control functions can be used simultaneously.

- DC1/DC3 transmission control
- DC1/DC3 reception control
- DC2/DC4 transmission control
- DC2/DC4 reception control

### DC1/DC3 transmission control, DC1/DC3 reception control

C24 informs the target device whether or not host station is ready to receive data by transmitting the DC1 and DC3 signals, and checks whether or not the target device is ready to receive data by receiving the DC1 and DC3 signals.

- DC1: Control data that notifies the target device that C24 is ready to receive data
- DC3: Control data that notifies the target device that C24 is not ready to receive data

Ex.

### C24 DC1/DC3 transmission control contents and free OS area specification

The control contents and the free OS area specification are the same as those of the DTR control. (Page 269 C24 DTR control contents and free OS area specification)

C24 operates depending on the capacity of free OS area as follows:

- Free area is 64 bytes (default) or less: DC3 transmission (reception disabled)
- Free area is 263 bytes (default) or more: DC1 transmission (reception enabled)

#### ■Remarks

- The receive data clear processing clears the data stored in the OS area. (The receive area in the buffer memory is not cleared.) (Page 70 Receive data clear)
- If more data is received when the above free OS area is 0 bytes, an SIO error occurs and the received data is ignored until a free area is available. In this case, the SIO signal turns ON. (Page 511 Hardware information communication error "SIO" occurs)

C24 DC1/DC3 reception control contents

- When C24 receives DC3 from the target device, it terminates data transmission.  
The program cannot read the received DC3 signal.
- When C24 receives DC1 from the target device, it restarts data transmission. (C24 resumes transmission from the data terminated by the DC3 reception.)  
The program cannot read the received DC1 signal.

- Once DC1 is received, subsequent DC1 is ignored and removed from the received data.

■Remarks

In the DC1/DC3 transmission/reception control, the state of C24 is as follows at the time of power-on, reset or mode switching of the CPU, or the UINI instruction execution.

- C24 does not transmit DC1 to the target device.
- C24 is in the same state as when it transmits DC1.
- C24 is in the same state as when it received DC1 even if DC1 is not received from the target device.

# DC2/DC4 transmission control, DC2/DC4 reception control

C24 encloses the data transmitted from the host station in the DC2 and DC4 codes and transmits it to the target device, and processes the data received from the target device enclosed in the DC2 and DC4 codes as valid data.

- DC2: Control data that informs the target device that the data following it is the start of the valid data
- DC4: Control data that informs the target device that the data immediately preceding it is the end of the valid data

Ex.

## C24 DC2/DC4 transmission control contents

When transmitting data to a target device, C24 adds the DC2 code to the head of the data to be transmitted and the DC4 code to the end of the data to be transmitted.

\* The DC2 and DC4 code are also added for communication using MC protocol.

## C24 DC2/DC4 reception control contents

- When DC2 is received from the target device, C24 processes the received data up to DC4 as valid data.  
The received DC2 cannot be read by the program.
- When DC4 is received from the target device, C24 ignores the received data up to the one immediately before DC2 as invalid data.  
The received DC4 cannot read by the program.

\*1 MC protocol 1C frame

- Once DC2 is received, subsequent DC2 is ignored and removed from the received data.

## 13.3 Considerations for Using Transmission Control Functions

The following describes the considerations for using the transmission control function of C24.

### Agreement between target device and CPU module

Determine the following between the target device and the CPU module.

- Whether or not the transmission control function is to be used. When it is used, which control is to be used for data communications.
- Control timing
- DC1 to DC4 codes when DC code control is performed  
(The DC1 to DC4 codes to be used can be arbitrarily changed.)

### Conditions to use the transmission control function

- DTR/DSR control and DC code control cannot be used at the same time.
- When using DTR/DSR control, connect the ER (DTR) and DR (DSR) signals on the C24 side to the target device.

### Transmission control function setting

Set the transmission control function that can control the target interface.

If a function that cannot control the target interface is set, the set contents are invalid.

### Setting of transmission control function during interlink operation

When the two interfaces of C24 is used as interlink operation, set the transmission control function to either one of interfaces of which transmission control is required.

Set the other interface to "Do not use transmission control function" (the setting values to directly set to the buffer memory is 0001H).

### DC code control

- DC1/DC3 transmission control and DC1/DC3 reception control are possible when full-duplex communications is used to communicate data between C24 and target devices.  
Do not use DC1/DC3 control for half-duplex communications.
- The same data as the DC1 to DC4 codes cannot be included in the user data.  
To handle the same data as a DC code as user data, perform any of the following:  
Use DTR/DSR control.  
Change the DC code. Do not use the transmission control function.

#### ■Remarks

If the user data received from the target device includes the relevant DC code when DC1/DC3 reception control and DC2/DC4 reception control are used, C24 performs the corresponding DC code control.

If the user data transmitted from the CPU module includes a DC code, it is sent unchanged.

### Handling of ER (DTR) and DR (DSR) signals when DTR/DSR control is not used

When the DTR/DSR control is not used, C24 handles the ER (DTR) and DR (DSR) signals as described below.

- ER (DTR) signal is always ON.
- The ON/OFF status of DR (DSR) signal is ignored.

# 14 DATA COMMUNICATIONS USING HALF-DUPLEX COMMUNICATIONS

This chapter explains the settings to prevent simultaneous transmission from C24 and the target device for data communication between them using the RS-232 interface.

The setting for each interface is available for RJ71C24-R2.

When C24 is started, full-duplex communications is set. The communication method can be changed by the user according to the specifications of the target device.

Point

Since the setting for half-duplex communications is not required in the following cases, this chapter can be skipped.

- When data is only transmitted or received during data communications using the nonprocedural protocol.
- When no data is transmitted from the target device to C24 without direction from C24 by the specifications of the target device.

## 14.1 Half-duplex Communications

The following describes the differences between full-duplex communications and half-duplex communications. Since C24 performs the communication controls on the C24 side with the communication method set by the parameter as shown below, control by a program is not necessary.

### Full-duplex communications

This is a communication method to communicate data with a target device like a conversation pattern with a telephone. C24 can receive data while transmitting data to the target device. It can also transmit data while receiving data from the target device.

### Half-duplex communications

This is a communication method to communicate data with a target device like a conversation pattern with a transceiver. When C24 receives data from the target device while transmitting data to the target device, it controls data transmission and reception according to 'simultaneous transmission priority/non-priority designation'. C24 does not transmit data while it is receiving data from the target device.

## 14.2 Data Transmission and Reception Timing

Half-duplex communications uses C24 RS-232 interface CD (DCD) and RS (RTS) signals to control communications.

If the target device can transmit and receive data according to ON/OFF of C24 RS (RTS) and CD (DCD) signals as shown below, half-duplex communications is possible.

- RS (RTS) signal : C24 turns ON/OFF this signal as shown below.

When data is transmitted from C24, this signal is turned ON. When transmission is completed, this signal is turned OFF.

- CD (DCD) signal: Turn ON/OFF this signal on the target device side as shown below.

To transmit data from the target device, turn ON this signal. When transmission is complete, turn OFF this signal.

The data transmission/reception timings for data communications with half-duplex communications are shown by the CD (DCD) signal and RS (RTS) signal of C24.

### Timing when transmitting data from target device

Transmit data by controlling C24 CD (DCD) signal according to the setting value for "simultaneous transmission priority/non-priority designation" of the parameter.

#### ■When C24 is designated to "Priority"

① When transmitting data, check the RS (RTS) signal. If the RS (RTS) signal is OFF, turn ON the CD (DCD) signal. If the RS (RTS) signal is ON, wait until it is turned OFF, then turn ON the CD (DCD) signal.

② Transmit data after turning ON the CD (DCD) signal.

③ After data transmission is completed, turn OFF the CD (DCD) signal.

④ If the RS (RTS) signal is turned ON during data transmission, terminate data transmission and turn OFF the CD (DCD) signal, and perform data reception processing. (Simultaneous transmission occurred.)

⑤ After transmission from C24 is completed, retransmit all the data terminated at the step ④.

\*1 Take the following measures between the devices communicating data as a countermeasure against ignoring received data by C24.

- Transmission and reception of a response message in reply to data transmission
- Time-out check of a response message and retransmission of data due to time-out error (target device side)

## ■When C24 is designated to "Non-priority"

The contents of steps ④ and ⑤ below are different from those of the case "Priority" is designated.

① When transmitting data, check the RS (RTS) signal. If the RS (RTS) signal is OFF, turn ON the CD (DCD) signal. If the RS (RTS) signal is ON, wait until it is turned OFF, then turn ON the CD (DCD) signal.

② Transmit data after turning ON the CD (DCD) signal.

③ After data transmission is completed, turn OFF the CD (DCD) signal.

④ Keep transmitting data to C24 even if the RS (RTS) signal is turned ON during data transmission. (Simultaneous transmission occurred.)

⑤ After transmission from the target device is completed, transmit data from C24 to the target device. (Page 278 Timing when transmitting data from C24)

\*1 For the transmission content, refer to the following section.

Page 278 Timing when transmitting data from C24

## ■Remarks

When using the DTR/DSR transmission control function, transmit data from the target device to C24 as shown below in both cases above. (Page 268 DATA COMMUNICATIONS USING DC CODE TRANSMISSION CONTROL)

- When C24 ER (DTR) signal is turned OFF, terminate data transmission.
- When C24 ER (DTR) signal is turned ON after data transmission is terminated, restart data transmission (transmit from the terminated part of the data).

## Timing when transmitting data from C24

Transmit data by controlling C24 RS (RTS) signal according to the setting value for "simultaneous transmission priority/non-priority designation" of the parameter.

### ■When C24 is designated to "priority"

① When transmitting data, check the C24 CD (DCD) signal. If the CD (DCD) signal is OFF, turn ON the C24 RS (RTS) signal. If the CD (DCD) signal is ON, wait until it is turned OFF, and then turn ON the RS (RTS) signal.

② Transmit the data after turning ON the RS (RTS) signal.

③ After data transmission is completed, turn OFF the RS (RTS) signal.

④ Keep transmitting data from C24 to the target device even if the CD (DCD) signal is turned ON during data transmission. (Simultaneous transmission occurred.)

⑤ After transmission from C24 is completed, transmit all the data terminated at step ④ from the target device to C24.

\*1 As a countermeasure against the disregard for the received data by C24, perform the following between the communicating devices.

- Transmission and reception of a response message in reply to data transmission.
- Time-out check of a response message and retransmission of data due to time-out error (target device side)

## 14

- \*1 The data equivalent to the setting value of "simultaneous transmission priority/non-priority" is not transmitted.

- Remarks**

- When the C24 DR (DSR) signal is turned OFF, terminate data transmission.
- When the C24 DR (DSR) signal is turned ON after data transmission is terminated, restart data transmission (transmit from the terminated part of the data).

## 14.3 Changing the Communication Method

To change the data communication method from full-duplex communication to half-duplex communication, setting the following parameters is required.

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

### RS-232 communication method designation

Set to "half-duplex communications".

### Simultaneous transmission priority/non-priority designation

Set whether to continue ("priority") or stop ("non-priority") transmission from C24 when C24 and the target device start data transmission simultaneously in half-duplex communications.

Setting values "1" to "255" to set to "Non-priority" will be the transmission wait time that elapses from when the resumption of data transmission becomes available until data is actually sent.

### Retransmission time transmission method designation

When "half-duplex communication" and "non-priority" are set as indicated above, this setting becomes valid. Set whether the terminated message will be transmitted from the beginning ('Resend') or from the terminated part of the message ('Do not resend') when C24 and the target device start transmission simultaneously, and C24 stops and then restarts transmitting.

### RS-232 CD terminal check designation

Set the CD terminal check designation to "Check".

## 14.4 Connector Connections for Half-duplex Communications

The following explains the connector that connects C24 and target device when half-duplex communications are used.

Connect to the target device in accordance with the following.

- Connect the C24 RS (RTS) signal to one of the target device signals (CS (CTS), DR (DSR), or CD (DCD) signal) for half-duplex communications.
- Connect the C24 CD (DCD) signal to one of the target device signals (RS (RTS) or DR (DSR) signal) for half-duplex communications.
- The half-duplex communications cannot be performed when an RS-232 and RS-422 converter is used.

| C24         |         | Cable connection and signal direction | Target device |
|-------------|---------|---------------------------------------|---------------|
| Signal name | Pin No. |                                       | Signal name   |
| CD(DCD)     | 1       |                                       | CD(DCD)       |
| RD(RXD)     | 2       |                                       | RD(RXD)       |
| SD(TXD)     | 3       |                                       | SD(TXD)       |
| ER(DTR)     | 4       |                                       | ER(DTR)       |
| SG          | 5       |                                       | SG            |
| DR(DSR)     | 6       |                                       | DR(DSR)       |
| RS(RTS)     | 7       |                                       | RS(RTS)       |
| CS(CTS)     | 8       |                                       | CS(CTS)       |
| CI(RI)      | 9       |                                       | —             |

# 14.5 Considerations for Half-duplex Communications

The following describes the considerations for using half-duplex communications.

## Half-duplex communications system configuration and functions

Half-duplex communications can be used only in a system configuration where the CPU module and a target device are connected on a 1:1 basis.

## Agreement and confirmation between target device and CPU module

Determine and confirm the following items between the target device and the CPU module.

- Whether or not half-duplex communications can be performed by C24 RS (RTS) signal and CD (DCD) signal.
- C24 RS (RTS) signal and CD (DCD) signal ON/OFF timing
- C24 and target device data transmission timing
- RS-232 cable connection method

## Transmission control

When the transmission control function is used, DC1/DC3 transmission control and DC1/DC3 reception control of the DC code control cannot be used with half-duplex communications. Therefore, do not designate them. (Page 268 DATA COMMUNICATIONS USING DC CODE TRANSMISSION CONTROL)

# 15 CONTENTS AND REGISTRATION OF USER FRAMES FOR DATA COMMUNICATION

User frames are used to register some part, or all of messages exchanged between a target device and C24 in advance and use them to check the data to be transmitted or received.

The following functions can use C24 user frames to transmit and receive data.

- MC protocol on-demand function. (  Page 299 ON-DEMAND DATA COMMUNICATIONS USING USER FRAMES)
- The data transmit/receive function using the nonprocedural protocol (  Page 308 DATA COMMUNICATIONS USING USER FRAMES)

Data can be transmitted and received by registering the corresponding user frames to C24 in advance to match the data contents that are transmitted and received between the target device and C24.

This chapter explains the data that can be registered, the data contents that are transmitted and received, and registering to C24 of user frames that can be used in data communications with the target device.

For information on how to use user frames in each data communication function, refer to the following sections.

 Page 299 ON-DEMAND DATA COMMUNICATIONS USING USER FRAMES

 Page 308 DATA COMMUNICATIONS USING USER FRAMES

## 15.1 User Frame Types and Contents During Communication

This section explains the types of user frames handled by C24 and the data contents that are transmitted and received.

The following two types of user frames are available. Either type can be used as a user frame.

| Frame type                 | Overview                                                                                                                                         | Reference                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| User frame                 | A frame that contains arbitrary data arranged according to the specifications of a target device. The data arrangement can be defined by a user. | Page 282 User frames to be registered and used by the user |
| Default registration frame | A frame that is registered in C24 in advance. The frame cannot be changed by a user.                                                             | Page 290 Default registration frame (read only)            |

### User frames to be registered and used by the user

The following explains data to be registered, data contents that are transmitted and received, and how C24 handles user frames registered C24 flash ROM or buffer memory by the user.

#### Overview

User frames registered by the user are frames that contain arbitrary data according to the specifications of the target device, and the data arrangement are determined by the user.

## User frame registration

Up to 80 bytes (80 characters) of data can be registered as 1 user frame.

Up to 231 user frames can be registered (written), read, and deleted to/from C24.

| Registration destination |                               | Maximum number of frames can be registered | Frame No.      | Application                                                                        | Remarks                                                        |
|--------------------------|-------------------------------|--------------------------------------------|----------------|------------------------------------------------------------------------------------|----------------------------------------------------------------|
| CPU module               | Built-in memory <sup>*1</sup> | 31 frames                                  | 8001H to 801FH | A user frame of which contents are changed after data communication has started    | —                                                              |
|                          | SD memory card <sup>*1</sup>  | 31 frames                                  | 8001H to 801FH | A user frame of which contents are changed after data communication has started    | —                                                              |
| C24                      | Flash ROM <sup>*1</sup>       | 200 frames                                 | 03E8H to 04AFH | A user frame of which contents is not changed after data communication has started | —                                                              |
|                          | Buffer memory                 | 31 frames                                  | 8001H to 801FH | A user frame of which contents are changed after data communication has started    | Registration by overwriting with MOV instruction is available. |

<sup>\*1</sup> For the priority of the registered data, refer to the following section.

☞ Page 434 PARAMETER REGISTRATION TO CPU MODULE

Registration data to handle variable data (Sum check code, C24 station number, etc.) as a part of the user frame can be included in the user frame. (☞ Page 283 Variable data)

User frames can be registered by overwriting to C24 buffer memory. (The preceding contents are destroyed.)

## Data that can be registered as user frame

Up to 80 bytes of data can be registered by combining 1 byte data of which registered code is 01H to FEH and 2 bytes data of which registered code is FFH + 00H to FFH + FFH.

### ■One byte data of which registered code is (01H to FEH)

This is the registered code for transmitting and receiving the data of which registered code is (01H to FEH).

### ■Two bytes data of which registered code is (FFH + 00H) to (FFH + FFH)

This is the registered code for transmitting and receiving the variable data (sum check code, C24 station number, etc.) as part of the user frame. (☞ Page 283 Variable data)

FFH is the registered code of the first byte for handling variable data.

## Variable data

"Variable data" is a generic term for the data shown below.

These variable data can be handled as part of a user frame.

- Sum check code covering a determined range of messages to be transmitted/received
- Horizontal parity code covering a determined range of message to be transmitted/received
- Two's complement sum check code covering a determined range of messages to be transmitted/received
- C24 station number
- One byte data in data transmission (00H (NULL), FFH)
- One byte of arbitrary data in data reception. (Used to handle an arbitrary byte of data as part of the user frame during reception check by C24.)

### ■Variable data designation method

Variable data is designated by combining registered code FFH and the data codes shown in the table below.

The sum check code, C24 station No., and other variable data can be handled according to FFH of the first byte and 00H to FFH of the second byte.

## ■Variable data designation contents, data contents transmitted and received, and handling by C24

The table below shows the registered codes (FFH+00H) to (FFH + FFH) combinations for handling variable data, the data contents that are transmitted and received, and how C24 handles the data.

| Variable data registered code |          | Data contents transmitted and received/C24 handling                                                                                                                                                 | Calculating range | Detailed explanation                                                                 |  |
|-------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|--------------------------------------------------------------------------------------|--|
| 1st byte                      | 2nd byte |                                                                                                                                                                                                     |                   |                                                                                      |  |

|                               | F9H      |                                                                                                                                                                                                     |                   |                                                                                      |  |
|                               | FFH      | Transmits and receives the registered code FFH data (1 byte).                                                                                                                                       | —                 | —                                                                                    |  |

\*1 During data communication using a user frame that handles the final frame, the contents of the "sum check code" in the transmission setting set by the parameter will be ignored.

## ■Calculating ranges for the registered codes

The following shows the calculating ranges for the registered codes.

| Calculating range |                             | Target range*1                                                                                                                                                                                                    |
|-------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Range 1           | When transmitting           | Range from the data following the start frame (the user frame (1st) when multiple user frames are designated) to the one immediately before the registered code                                                   |
|                   | When receiving              | Range from the data following the start frame to the one immediately before the registered code                                                                                                                   |
| Range 2           | When transmitting/receiving | Range from the head of a message to the data immediately before the registered code                                                                                                                               |
| Range 3           | When transmitting           | Range from the data following the start frame (the user frame (1st) when multiple frames are designated) to the one immediately before the final frame (the user frame (nth) when multiple frames are designated) |
|                   | When receiving              | Range from the data following the start frame to the one preceding the final frame                                                                                                                                |
| Range 4           | When transmitting/receiving | Range from the head of a message to the data preceding the final frame                                                                                                                                            |

\*1 The additional code data for the transparent code designation shown below is excluded.

☞ Page 358 TRANSPARENT CODES AND ADDITIONAL CODES

## Variable data registered code

### ■C24 processing to the registered code FFH+00H

The following shows an example to describe the processing performed by C24 when it receives a user frame portion corresponding to registered codes FFH and 00H.

When setting a user frame containing the data codes 02H, FFH, 00H, and 3BH for a receive user frame as user frame number, 3EAH

- C24 performs the reception processing as the user frame, 3EAH has been received when it receives 3 bytes of data, "STX, arbitrary data (for 1 byte), ;".
- C24 does not check the 2 bytes described above.

### ■C24 processing to the registered code FFH+01H

C24 transmits and receives the user frame portion corresponding to registered code, FFH+01H by representing the station number set in the parameter as 1-byte binary data.

For the usage example, refer to the start frame portion in the figures below.

☞ Page 286 C24 processing to registered codes FFH+04H, FFH+05H, FFH+0AH, and FFH+0BH

## ■C24 processing to registered codes FFH+04H, FFH+05H, FFH+0AH, and FFH+0BH

- For FFH + 04H and FFH + 0AH

The horizontal parity code that calculates the range for the data to be transmitted/received (message) is expressed as 1 byte binary data and then transmitted and received.

The difference between FFH + 04H and FFH + 0AH is the difference in the calculating range.

- For FFH + 05H and FFH + 0BH

The horizontal parity code that calculates the range for the data to be transmitted/received (message) is expressed as 2-byte ASCII code data and then transmitted and received from the upper digit.

The difference between FFH + 05H and FFH + 0BH is the difference in the calculating range.

**Ex.**

Examples of data arrangement when the horizontal parity code is transmitted/received are shown below. (The start frame and final frame are equivalent to one frame respectively.)

- For registered code FFH + 04H

- For registered code FFH + 05H

- How to calculate the horizontal parity code

This is a numeric value obtained by calculating the XOR for the subject data and then converting it to ASCII code.

**Ex.**

For message example above

```

"1" (31H) 0011 0001
           XOR
"2" (32H) 0011 0010 = 0000 0011
           XOR
"3" (33H) 0011 0011 = 0011 0000
           XOR
"4" (34H) 0011 0100 = 0000 0100
           XOR
"ETX" (03H) 0000 0111 = 0000 0111
               ↓      ↓
               "0"    "7"

■C24 processing to registered codes FFH+11H and FFH+17H

The two's complement sum check code that calculates the range for data (message) to be transmitted/received is expressed as two character data in ASCII code, then transmitted and received from the upper digit.

The difference between (FFH+11H) and (FFH+17H) is the difference in the calculating ranges.

An example of the contents (arrangement) of the transmission and reception of the two's complement sum check code is shown below.

Ex.

Arrangement of data transmitted and received with the registered code FFH+17H (The start frame and final frame are equivalent to one frame respectively.)

• How to calculate the two's complement sum check code

The lower 1 byte of the value obtained by adding the subject data as binary data is converted to a two's complement, then converted to a hexadecimal ASCII code.

Ex.

For message example above

02H+00H+3BH+31H+32H+33H+34H+03H=10AH ----- ● Data in the subject range are added as binary data (hexadecimal)

↓  
00001010 ----- ● The lower 1 byte of the above numeric value is expressed as a binary number  
↓  
11110110 ----- ● Reversed, then converted to a two's complement  
↓  
F6H ----- ● Converted to a hexadecimal ASCII code  
↓  
"F" "6"  
(46H) (36H)

■C24 processing to registered codes FFH+EEH to FFH+F9H

The sum check code that calculates the range for data (message) to be transmitted/received is expressed as the binary code/ASCII code data listed below, then transmitted and received.

| Registered code        | Data contents transmitted and received                                                                               |
|------------------------|----------------------------------------------------------------------------------------------------------------------|
| FFH + EEH or FFH + F4H | The lower 2 bytes of the calculated sum check code are transmitted and received as 2-byte binary code data.          |
| FFH + F0H or FFH + F6H | The lower byte of the calculated sum check code is transmitted and received as 1-byte binary code data.              |
| FFH + F1H or FFH + F7H | The lower byte of the calculated sum check code is converted to 2-digit ASCII code, then transmitted and received.   |
| FFH + F3H or FFH + F9H | The lower 4 bits of the calculated sum check code is converted to 1-digit ASCII code, then transmitted and received. |

An example of the contents (arrangement) of the transmission and reception of the sum check code is given below.

Ex.

Arrangement of data transmitted and received (one start frame and one final frame)

- How to calculate the sum check code and data contents transmitted and received  
This is a numeric value obtained by adding data in the above range as binary data.

Ex.

For Range 1: 41H+ 31H + ABH + 12H + 03H = 0132H

For Range 2: 02H + 00H + 3BH + 41H + 31H + ABH + 12H + 03H = 016FH

| Calculating range | Registered code | Data contents transmitted and received (arrangement)          |
|-------------------|-----------------|---------------------------------------------------------------|
| Range 1           | FFH + EEH       | 01H and 32H are transmitted and received, beginning from 32H. |
|                   | FFH + F0H       | 32H is transmitted and received.                              |
|                   | FFH + F1H       | "3" and "2" are transmitted and received, beginning from "3." |
|                   | FFH + F3H       | "2" is transmitted and received.                              |
| Range 2           | FFH + F4H       | 01H and 6FH are transmitted and received, beginning from 6FH. |
|                   | FFH + F6H       | 6FH is transmitted and received.                              |
|                   | FFH + F7H       | "6" and "F" are transmitted and received, beginning from "6". |
|                   | FFH + F9H       | "F" is transmitted and received.                              |

### ■C24 processing to registered code FFH+E5H

The sum check code that calculates data (message) to be transmitted/received excluding the first one frame and last one frame is expressed as the ASCII code data and transmitted or received.

- How to calculate the sum check code

Lower one byte of the calculated sum check code is converted into 2-digit ASCII code data, and transmitted and received.

**Ex.**

Arrangement of data when transmitted/received

### ■C24 processing to registered code FFH+EBH

The sum check code that calculates the data (message) to be transmitted/received, including the first one frame and excluding the last one frame, is expressed as the ASCII code data, and transmitted or received.

- How to calculate the sum check code

Lower one byte of the calculated sum check code is converted into 2-digit ASCII code data, and transmitted or received.

**Ex.**

Arrangement of data when transmitted/received

## Default registration frame (read only)

This frame is registered in C24 in advance and can be used in the same way as the other user frames.

### Overview

The default registration frame is registered in the operating system ROM of C24.

The one-byte data (code: 01H to FEH) and a maximum of five-byte data is registered, and can be used for read-only. (Frame No.: 1H to 3E7H)

Each of these frames is treated as a user frame.

### Default registration frame registered data and data contents transmitted and received

The codes of the registration data for default registration frame and the data contents that are transmitted and received are shown below.

| Default registration frame No.<br>(HEX (DEC)) | Registration data code<br>(1st byte to nth byte) | Registered<br>byte count | Frame byte count | Data contents transmitted<br>and received |
|-----------------------------------------------|--------------------------------------------------|--------------------------|------------------|-------------------------------------------|
|                                               |                                                  |                          |                  | Data contents                             |
| 1H (1)                                        | 01H                                              | 1                        | 1                | (Data of code shown at the left)          |
| 2H (2)                                        | 02H                                              |                          |                  | STX                                       |
| ⋮                                             | ⋮                                                |                          |                  | ⋮                                         |
| FEH (254)                                     | FEH                                              |                          |                  | (Data of code shown at the left)          |
| FFH (255)                                     | —                                                | —                        | —                | (For variable data designation)           |
| 100H (256)                                    | 00H                                              | 1                        | 1                | NUL                                       |
| 101H (257)                                    | FFH                                              | 1                        |                  | (Data of code shown at the left)          |
| 102H (258)                                    | 0DH, 0AH                                         | 2                        | 2                | CR, LF                                    |
| 103H (259)                                    | 10H, 02H                                         |                          |                  | DLE, STX                                  |
| 104H (260)                                    | 10H, 03H                                         |                          |                  | DLE, ETX                                  |
| 105H (261)                                    | 00H, FEH                                         | 2                        | 2                | (Data of codes shown at the left)         |

| 119H (281)                                    | FFH, F9H                                         |                          |                  |                                           |
| 11FH (287)                                    | FFH, FFH                                         |                          |                  |                                           |
| 120H (288)                                    | (None)                                           |                          |                  |                                           |
| ⋮                                             | ⋮                                                |                          |                  |                                           |
| 3E7H (999)                                    | ⋮                                                |                          |                  |                                           |
|                                               |                                                  |                          |                  | Registered code FFH data (1 byte)         |

\*1 The combination of FFH, □□H in the registered code is used to handle variable data (sum check code, C24 station number, etc.) as part of the user frame.

The data contents that are transmitted and received and the byte count depend on the code combined with registered code FFH.

For combination of registered code to handle variable data and the data contents transmitted/received, refer to the following section.

📖 Page 283 Variable data

# 15.2 Transmission/Reception Processing Using User Frame Registration Data

The following explains how C24 transmits and receives using user frame registration data.  
C24 checks the transmission/reception of following data, using registered data.

## Transmitting data

### When user frame transmission is designated

A user frame is converted or not converted from ASCII to binary data and transmitted, depending on the data communications protocol, ASCII-BIN conversion designation, and user frame No. designation, based on the following data as the send data of the given part.

#### Registered portion of 1-byte data for code of registration data, 01H to FEH

C24 transmission is based on the data for registered code (01H to FEH).

Ex.

When data codes 03H, 0DH, and 0AH are registered as user frame number, 3E8H  
When user frame number, 3E8H is designated during data transmission, C24 transmits the data codes 03H, 0DH, 0AH (ETX, CR, LF) as the data to be transmitted for the given user frame if ASCII-BIN conversion is disabled.  
When ASCII-BIN conversion is enabled, C24 converts each of the data above to 2-byte ASCII code data and transmits.

#### Registered portion of 2-byte data for code of registration data, FFH+00H to FFH

C24 transmission is based on the variable data corresponding to the combination of the registered codes FFH and 00H to FFH.  
For example, if sum check code is registered, C24 will calculate and transmit the sum check code. If C24 station No. is registered, the station number set to C24 is transmitted.

Ex.

When data codes 03H, FFH, F0H, 0DH, 0AH are registered as user frame number, 3E9H  
When user frame number, 3E9H is designated during data transmission, C24 calculates the sum check code as the data to be transmitted for the given user frame portion. If ASCII-BIN conversion is disabled, C24 transmits the calculated data. If ASCII-BIN conversion is enabled, C24 converts the calculated data to 2 bytes per byte ASCII code data and transmits.

■Remarks

With the multidrop connection, including data for the target device to identify which station transmitted a message in the user frame can facilitate creation of arbitrary data to be transmitted.

## Receiving data

### When user frame reception is designated

When the start frame is set, C24 receives the message when it receives data with the same arrangement as the designated start frame.

If the final frame is set, C24 issues the read request of received data to the CPU module when it receives data with the same arrangement as the designated final frame.

### C24 reception processing by registration data

#### ■Registered portion of 1-byte data for code of registration data, 01H to FEH

C24 receives and checks if the received data is data of the same code (01H to FEH) as the registered code.

Ex.

When data codes 03H, 0DH, and 0AH are registered as user frame number, 3E8H

When user frame No. 3E8H is set for data reception, C24 receives and checks data codes 03H, 0DH, 0AH (ETX, CR, LF) as the receive data of that user frame portion.

■Registered portion of 2-byte data for code of registration data, FFH+00H to FFH

C24 receives and checks if the received data is variable data corresponding to the combination of the registered codes FFH and 00H to FFH.

For example, if a sum check code is registered, C24 calculates the sum check code from the receive data and checks if it is the same as the received sum check code. If the two codes are not the same, C24 performs error processing.

If C24 station number is registered, C24 checks if the received station number is the same as the station number set in C24. If the two station numbers are not the same, C24 processes the data as if normal data was received instead of a user frame.

Ex.

When data code 03H, FFH, F0H, 0DH, 0AH is registered as user frame number, 3E9H

When user frame No. 3E9H is set for data reception, C24 calculates, receives, and checks the sum check code as the receive data of that user frame portion.

■In a reception message

C24 removes the user frame data portion from the reception message.

(The CPU module cannot read this data.)

■Remarks

With the multidrop connection, the module on a given station stores only arbitrary data portion of a message transmitted by the target device in the receive data storage area by registering each receive user frame specific to respective modules to be connected.

## 15.3 Considerations for Registering, Reading, and Deleting User Frames

The following shows the considerations for registering user frames and using registered user frames to transmit data to and receive data from the target device normally.

### Considerations for registering, reading or deleting user frames

#### ■Registration of user frame

A user frame can be registered using one of the following methods.

- Registering by using the module extended parameters. (📖 Page 297 Registration method using module extended parameters)
- Registering with the dedicated instruction "PUTE" from the CPU module. (📖 MELSEC iQ-R Programming Manual (Module Dedicated Instructions))
- Registering from a target device with command "1610" through communications using the MC protocol. (📖 MELSEC Communication Protocol Reference Manual)

When a user frame is registered using the dedicated instruction or the MC protocol after the registration to the CPU built-in memory or SD memory card by module extended parameters, it is replaced with the contents registered using module extended parameters by powering OFF → ON or switching the CPU module STOP → RUN.

#### ■Setting required to register/delete user frame

The following settings are required when registering or deleting user frames.

- Set "Setting change" to "Enable" in the transmission setting of the parameter.

#### ■Registering, reading or deleting user frames from the CPU module

Register/read/delete a user frame when no data is communicated with the target device.

#### ■Registration of sum check code

A user frame only with sum check code for variable data cannot be registered.

To register sum check code, add arbitrary data.

#### ■User frame to be used for reception

Register a receive user frame in the CPU module or the flash ROM of C24.

#### ■Designation of variable data

The variable data (05H to F9H) can be designated at only one place in the final frame.

Considerations for using user frames

■Transmitting/receiving data using user frames

It is necessary to set the user frame number to be used to the buffer memory prior to data transmission/reception (receive user frames must be set at the startup of C24).

■Data communication procedure when the number for a receive user frame is set from the CPU module

The procedure to set a receive user frame number from the CPU module and receive data is shown below.  
Receive user frame data by performing the following operations sequentially.

- Restart the CPU module when a user frame to be used for data reception was registered from the CPU module.
- Set the receive user frame number to the buffer memory at the startup of C24, and write "1" in the 'User frame use enable/disable designation' (Un\G173/333) on the buffer memory.
- Start data reception once the value in the user frame use enable/disable designation area on the buffer memory changes to "2".
- Check whether data is received normally from the target device.

■When additional code data is received during data reception using the nonprocedural protocol

C24 does not assume that 1-byte data immediately after it is data for the following controls.

- Data received as the start frame, final frame for user frame (  Page 282 User Frame Types and Contents During Communication,  Page 291 Transmission/Reception Processing Using User Frame Registration Data)
- Receive end code data

Therefore, do not set a user frame containing data receive additional code data as a user frame for data reception using the nonprocedural protocol.

■Arbitrary data portion in a message received from a target device

The arbitrary data portion of a message received from a target device cannot include data with the same arrangement (same code) as the final frame.

Ex.

■Data bit length of transmission specification

In the following cases, set the data bit length of the transmission specification to 8 bits.  
(Set this in "Transmission Setting" of the parameter with Engineering tool for the C24 side.)

- When transmitting and receiving the sum check code of the variable data as binary data (registered code: FFH+EEH, FFH+F0H, FFH+F4H, FFH+F6H)
- When transmitting and receiving a user frame containing data codes 80H to FFH

# 15.4 Registering/Reading/Deleting User Frames

This section explains registering, reading, and deleting user frames in/from C24 flash ROM or buffer memory.

## Type of user frames

| Type                                                               |                            | User frame No.                                     | Registration destination                | Remarks                       |
|--------------------------------------------------------------------|----------------------------|----------------------------------------------------|-----------------------------------------|-------------------------------|
| Data communication function                                        | Default registration frame | 1H to 3E7H<br>(1 to 999)                           | ROM for C24 operating system            | Read enabled                  |
|                                                                    | User frame                 | 3E8H to 4AFH <sup>*1,*2</sup><br>(1000 to 1199)    | C24 flash ROM                           | Register/read/delete enabled  |
|                                                                    |                            | 8001H to 801FH <sup>*3</sup><br>(-32767 to -32737) | C24 buffer memory<br>(UnlG6912 to 8182) |                               |
| User frame for the programmable controller CPU monitoring function |                            | B001H to B00AH, B061H,<br>B080H to B082H           | ROM for C24 operating system            | Register/read/delete disabled |

- \*1 A user frame cannot be overwritten for registration. To reregister a user frame having the same number, first delete the current user frame and then reregister.
- \*2 Check the registration status of the user frame number with Engineering tool.
- \*3 The data arrangement of user frame for registration or reading is the same as the one for registration or reading to/from the flash ROM. Register or read user frames in accordance with the arrangement above.  
Although user frames can be registered in the buffer memory, register user frames of the fixed format portion in the flash ROM as much as possible.

## Devices that can register/read/delete user frames

| Type                                                               | User frame No.                        | Device that can register/read/delete |                 |                 |               |      |        |                  |      |        |
|--------------------------------------------------------------------|---------------------------------------|--------------------------------------|-----------------|-----------------|---------------|------|--------|------------------|------|--------|
|                                                                    |                                       | CPU module                           |                 |                 | Target device |      |        | Engineering tool |      |        |
|                                                                    |                                       | Register                             | Read            | Delete          | Register      | Read | Delete | Register         | Read | Delete |
| Default registration frame                                         | 1H to 3E7H                            | ×                                    |                 |                 | ×             | ○    | ×      | ×                |      |        |
| User frame                                                         | 3E8H to 4AFH                          | ○ <sup>*1</sup>                      | ○ <sup>*2</sup> | ○ <sup>*1</sup> | ○             |      |        | ○                |      |        |
|                                                                    | 8001H to 801FH                        | ○                                    |                 |                 |               |      |        | ×                |      |        |
| User frame for the programmable controller CPU monitoring function | B001H to B00AH, B061H, B080H to B082H | ×                                    |                 |                 |               |      |        |                  |      |        |

- \*1 Use the PUTE instruction.
- \*2 Use the GETE instruction.

## Precautions

Register/read/delete user frames by a program while no data is communicated with the target device.

## Registration method using module extended parameters

Register the user frame to be used for "Registration frame No. 1000" to "Registration frame No. 1199".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ Module Name ⇒ [Module Extended Parameter] ⇒ "User frame contents"

## Buffer memory to be used

Requirement for reading/writing from CPU module

○: Always performed, △: Performed as required, ×: Unnecessary

| Address<br>(Hexadecimal<br>(decimal)) | Name                                                                                   |                                                                                                                                                                                                                                                                 | Stored value                                                                                                                                                           | Processing |      |        |

## ■Registration data byte count designation (Un\G5, 6912, 6953, ..., 8142)

- The total number of bytes of registration data of user frame to be registered (written)/read is indicated.
- Accessing to the flash ROM  
At the time of registration, the user writes the total number of bytes of registration data.  
At the time of reading, the total number of bytes of registration data is stored.
- Accessing to the buffer memory  
At the time of registration, the user writes the total number of bytes of registration data.

## ■User frame (Un\G6 to 45, 6913 to 6952, 6954 to 6993, ..., 8143 to 8182)

- During the registration, the user sequentially stores the registration data of the user frame to be registered in the order of (L) and (H), beginning from the head area of the given area range.
- During the reading, the registration data of the registered user frame is stored with the same contents and arrangement as when registering.

**Ex.**

Contents stored in the user frame storage area when a user frame to transmit and receive ETX, sum check code, CR, and LF (registered codes: 03H, FFH, F1H, 0DH, 0AH) is registered to the flash ROM.

## ■User frame registration status (For registration number check) (Un\G517 to 541)

- The registration status of user frames to the flash ROM is stored with the values shown below.
- The contents of each area that indicates the registration status are shown below. The contents of the area are indicated in one user frame number/1 bit form.

**Ex.**

# 16 ON-DEMAND DATA COMMUNICATIONS USING USER FRAMES

During communications between a target device and a CPU module using the MC protocol, on-demand data can be transmitted from the CPU module to the target device with the on-demand function using user frames.

This chapter explains the transmission of the data specified by the CPU module using a message format other than the formats ( 1C frame format 1 to 4, 4C frame format 5) described in the following manual.

( MELSEC Communication Protocol Reference Manual)

## 16.1 Data Communication Function Using User Frame

The data communication using user frame means transmitting/receiving the first and last parts of a message in the format selected by a user in data communications between the CPU module and target devices via C24.

By using the function described in this chapter, on-demand data in the order shown below can be transmitted from C24 to the target device.

**Ex.**

Transmitting data according to the order of 3C frame, format 1

Data can be communicated using the user frames by registering in advance (by data codes) message formats that can be transmitted/received by the target device according to its specifications as user frames in C24.

In the above figure, C24 transmits the on-demand data as described below:

- Sum check code of a user frame  
C24 calculates the sum check code according to the contents registered in advance by the user, and transmits it as ASCII/binary data.
- Other than sum check code of a user frame  
C24 transmits data of the code registered in advance by the user. (No conversion)
- Send data (character B portion)  
This is the data that the program requested to transmit with ONDEMAND instruction.  
It is transmitted with the same contents and in the same order as the one transmitted without using a user frame according to the communication protocol and word/byte designation by the parameters of Engineering tool. ( MELSEC Communication Protocol Reference Manual)

## 16.2 User Frame On-Demand Data Transmission and Buffer Memory Used

This section explains the on-demand data transmission processing using a user frame and the arrangement of on-demand data based on the user frame specification to the buffer memory.

### Transmission of on-demand data using user frames

The following describes the transmission of on-demand data using user frames.

#### ■Processing on the CPU module side

- Before issuing a transmission request to C24, set the No. of the user frame registered in C24 to the buffer memory shown in the table below.
- The execution procedures and control procedures of the CPU module side excluding the above are the same as transmitting on-demand data without user frame described in the following manual.  
( MELSEC Communication Protocol Reference Manual)

#### ■Processing of the target device side

- When the target device receives the user frame transmitted by C24 as the start frame, receive it as on-demand data.

### Buffer memory to be used and the order of on-demand data

#### ■Buffer memory to be used

For on-demand data transmission using a user frame, the user frame to be transmitted is designated in the buffer memories shown below.

| Address |      | Name                               |                             |       | Description                                                                                                                                                                                                                                                              |

| ACH     | 14CH |                                    |                             | (2nd) |                                                                                                                                                                                                                                                                          |

- \*<sup>1</sup> Designates the registration No. (shown below) of the user frame to be transmitted from among the user frames registered in C24.  
 1H to 3E7H (1 to 999) : Default registration frame  
 3E8H to 4AFH (1000 to 1199) : User frame (registered in flash ROM)  
 8001H to 801FH (-32767 to -32737) : User frame (registered in buffer memory)

#### ■On-demand data arrangement

The following shows the order of on-demand data by user frame specification.

## ■Combination

Only the following combinations can be used for arrangement of on-demand data by user frame specification.

○: designated data

| Combination | Data name         |                   |           |                   |                   |
|-------------|-------------------|-------------------|-----------|-------------------|-------------------|
|             | Start frame (1st) | Start frame (2nd) | Send data | Final frame (1st) | Final frame (2nd) |
| 1           | ○                 | ○                 | ○         | ○                 | ○                 |
| 2           | ○                 | ○                 | ○         | ○                 |                   |
| 3           | ○                 | ○                 | ○         |                   |                   |
| 4           | ○                 | ○                 |           |                   |                   |

## ■Description of data to be transmitted

- The outline of data to be transmitted for on-demand data transmission by user frame specification is shown below.

| Contents of data to be transmitted                                                                                                                 |                                                                  | Communication with ASCII code                                                                             | Communication with binary code                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| User frame <ul style="list-style-type: none"> <li>Start frame (1st)</li> <li>Final frame (Last 1 frame)</li> </ul>                                 | The portions of which registered code is from 00H to FEH         | The data of the code registered in C24 is transmitted. (No conversion)                                    |                                                                                                                                                   |
|                                                                                                                                                    | Combined portions of which registered code is FFH and 00H to FFH | The data according to the user-designated contents, code, and number of bytes is transmitted.             |                                                                                                                                                   |
| User frame <ul style="list-style-type: none"> <li>Start frame (2nd)</li> <li>Final frame (Other than last 1 frame)</li> </ul>                      | The portions of which registered code is from 00H to FEH         | The data of the code registered in C24 is converted to ASCII data and transmitted.                        | The data of the code registered in C24 is transmitted.<br>For 10H data, the data of 10H + 10H is transmitted.                                     |
|                                                                                                                                                    | Combined portions of which registered code is FFH and 00H to FFH | The data of the contents, code, and number of bytes designated by the user to ASCII data and transmitted. | The data of the contents, code, and number of bytes designated by the user is transmitted.<br>For 10H data, the data of 10H + 10H is transmitted. |
| Send data<br>(  MELSEC Communication Protocol Reference Manual) | —                                                                | The designated send data is converted to ASCII data and transmitted.                                      | The designated send data is transmitted by the code unchanged. (No conversion)<br>For 10H data, the data of 10H + 10H is transmitted.             |

## 16.3 On-Demand Function Control Procedure During User Frame Use

This section explains the control procedure when on-demand data is transmitted to a target device with the on-demand function by using a user frame.

### Data communication using the ASCII code

Control procedure when two-word send data (1234H, 5678H) is designated by ONDEMAND instruction

- Set the "Communication protocol setting" to any one of "MC protocol (Format 1)" to "MC protocol (Format 4)".
- Set the "Station number" to "0".
- Set the "Word/byte units designation" to word unit.
- Set the "On-demand user frame specification" items to the following:

Start frame No. 1st: 02H

Start frame No. 2nd: 3EBH

Final frame No. 1st: 401H

Final frame No. 2nd: 0H (No specification)

- User frame registration

| User frame No. | User frame (Registered code) | Contents of user frame registration                                     |
|----------------|------------------------------|-------------------------------------------------------------------------|
| 02H (2)        | 02H                          | Data code from STX to host station number matched to 3C frame, format 1 |
| 3EBH (1003)    | F9H, 00H, 00H, FFH, FFH, 00H |                                                                         |
| 401H (1025)    | 03H, FFH, F1H                | Data code of ETX, sum check code equivalent to 3C frame, format 1       |

## Data communications using the binary code

Control procedure when two-word send data (1234H, 5678H) is designated by ONDEMAND instruction

- Set the "Communication protocol setting" to "MC protocol (Format 5)".
- Set the "Station number" to "0".
- Set the "Word/byte units designation" to word unit.
- Set the "On-demand user frame specification" items to the following:
  - Start frame No. 1st: 3ECH
  - Start frame No. 2nd: 0H (No specification)
  - Final frame No. 1st: 402H
  - Final frame No. 2nd: 0H (No specification)
- User frame registration

| User frame No. | User frame (Registered code) | Contents of user frame registration                                                     |
|----------------|------------------------------|-----------------------------------------------------------------------------------------|
| 3ECH (1004)    | 02H, FFH, 01H, 3BH           | STX + C24 station No. +;                                                                |
| 402H (1026)    | 03H, FFH, F0H, 0DH, 0AH      | ETX + sum check code + CR + LF<br>Sum check code is designated by one byte binary code. |

# 16.4 Example of On-Demand Data Transmission Program Using User Frames

The following shows a program example when transmitting on-demand data including user frames.  
Configure the settings and perform registration with Engineering tool in advance.

## On-demand data transmission program using user frames

### ■Input/output signal of C24

Install C24 in the position where the I/O signal is X/Y00 to X/Y1F.

### ■C24 interface used for communication with target device

CH1 side RS-232 interface of C24

### ■Parameter settings

| Setting item         |                               |                                                    | Setting value                           |
|----------------------|-------------------------------|----------------------------------------------------|-----------------------------------------|
| Basic settings       | Various control specification | Communication protocol setting                     | MC protocol (format 1)                  |
|                      |                               | Communication speed setting                        | 19200 bps                               |
|                      |                               | Transmission setting                               | Data bit                                |
|                      |                               |                                                    | Parity bit                              |
|                      |                               |                                                    | Odd/even parity                         |
|                      |                               |                                                    | Stop bit                                |
|                      |                               |                                                    | Sum check code                          |
|                      |                               |                                                    | Online change                           |
|                      |                               |                                                    | Setting change                          |
|                      |                               | Station number setting (CH1, 2 in common: 0 to 31) | 0                                       |
|                      |                               | Communication control specification                | Word/byte units designation             |
| Application settings | User frame specification      | Send wait time specification                       | Transmission wait time designation      |
|                      |                               | On-demand function specification                   | Buffer memory start address designation |
|                      |                               |                                                    | Data length designation                 |
|                      |                               | On-demand user frame specification                 | Start frame No. designation (1st)       |
|                      |                               |                                                    | Start frame No. designation (2nd)       |
|                      |                               |                                                    | Final frame No. designation (1st)       |
|                      |                               |                                                    | Final frame No. designation (2nd)       |

### ■Program example

Transmit the on-demand data with the on-demand function, and designate the two-word data to be transmitted with the ONDEMAND instruction.

The data in the user frame portion of the on-demand data to be transmitted is the registered data of the user frame number registered with Engineering tool.

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Description                                             | Device     |                       |            |           |       |                       |   |                        |     |            |     |   |                                        |     |            |      |   |                                          |     |            |      |   |                   |     |            |     |   |                                             |     |            |    |   |                                            |     |            |    |   |                                           |     |            |    |   |                                            |     |            |     |   |                      |                                     |            |    |    |                        |                                     |            |    |    |                     |                                     |            |    |    |                    |                                           |            |     |

For information on the module FB to be used, refer to the following manual.

- (0) On-demand transmission direction pulse
- (3) Set the transmission channel to the CH1 side.  
Set the send data quantity to two-word.  
Set the data to be transmitted.  
Reset the normal completion flag.  
Reset the abnormal completion flag.  
Set the execution direction.
- (61) Normal completion
- (63) Abnormal completion
- (65) Reset the execution direction.

## 16

### Point

- The SPBUSY instruction is used to read the communication status by the dedicated instruction. (  Page 580 Dedicated Instructions)
- Designate the storage capacity for send data (stored in D10 to D11 in the above program example) and data length (stored in D2 in the above program example) so that they do not exceed the range of buffer memory assigned by the user for the on-demand function.

# 17 DATA COMMUNICATIONS USING USER FRAMES

Registering the fixed format portion of the message transmitted/received by a target device and C24 as a user frame beforehand allows data transmission/reception using a user frame.

Data transmission/reception using a user frame simplifies the creation of data to be transmitted on the CPU module side, and the program for checking received data.

This chapter explains the data transmission/reception methods and procedures when communication data using user frames with the nonprocedural protocol of C24.

## Point

For details on "Transparent code" and "ASCII-BIN conversion", refer to the following chapters.

- When using transparent codes (➡ Page 358 TRANSPARENT CODES AND ADDITIONAL CODES)
- When performing data communication using ASCII-BIN conversion (➡ Page 379 COMMUNICATING WITH ASCII CODE (ASCII-BIN CONVERSION))

# 17.1 Procedure of Data Communication

This section explains an overview of the procedure when performing data communication between a target device and a CPU module using a user frame.

\*6 Page 345 Data Transmission

# 17.2 Data Reception

When receiving data using a user frame, the reception method on C24 side includes Method 0 and Method 1. The following explains data reception for each method.

## Receive data

In data reception using a user frame, data arranged as indicated below can be received.

### \*1 User frames for receiving

- The user frame for data reception can be set to a maximum of four combinations of the start frame and the final frame, regardless of whether there is a specification.
- For a combination that specifies the start frame (with a start frame), specifying the start frame is required even in other combinations.
- For a combination that does not specify the start frame (without a start frame), the start frame cannot be specified even in other combinations.
- A combination with the start frame and a combination without the start frame cannot be combined.

### \*2 If data of other than 30H to 39H and 41H to 46H are received as the data code of the arbitrary data area (including the transparent code data), an error will occur after the C24 ASCII-BIN conversion processing.

### \*3 Arbitrary data portion of received data

When the arbitrary data portion is stored to the receive area, and the storage byte quantity is an odd number of bytes, the receive data quantity shown below is stored to the receive data quantity storage area. (When ASCII-BIN conversion is enabled, the receive data quantity is the storage byte count when the arbitrary data portion is converted to binary code and stored to the receive area.)

· Word units: Receive data quantity = Number of bytes stored to receive area ÷ 2 (Digits after a decimal points are rounded up.)

· Byte units: Receive data quantity = Number of bytes stored to receive area

(00H is stored to the upper byte of the last data storage location of the receive area.)

When "ASCII-BIN conversion" is enabled, make the arbitrary data part of the receive data an even number of bytes excluding the additional code.

### Handling of received data by C24

- When a user frame (start frame, final frame) registered to C24 is received, the reception processing by user frame is performed.
- Of the start frame No. and final frame No. (maximum 4 sets) set in default by the user for the user frame specification for receiving area in buffer memory, the set number (nth) of the user frame received from the target device is stored to the receive user frame storage area.
- When a transparent code for receiving is specified, the additional code data included in the arbitrary data portion is deleted immediately after reception (or, before conversion when ASCII-BIN conversion is performed).

## Reception with the start frame (combination 1-A to C) (reception using Method 0)

### ■Reception of combination (1-A)

This is a method that any data portion of a reception message which can be handled by the CPU module side is enclosed by a start frame and a final frame and transmitted from a target device.

C24 starts the reception processing when data of the same arrangement as the start frame is received.

When data of the same arrangement as the final frame is received, the arbitrary data is stored in the receive area on the buffer memory and a read request is issued to the CPU module.

### Precautions

- Any received data prior to the start frame will be ignored.
- Set a data quantity that exceeds the size of the arbitrary data portion to be received for the receive end data quantity initially set to C24.
- Reception processing by the receive end code initially set to C24 will not be performed. Received data of a receive end code are treated as an arbitrary data portion.

**Ex.**

When data transmitted from a bar code reader is received

Register STX as the start frame and register ETX as the final frame according to the message format of the bar code reader.

## ■Reception of combination (1-B)

This is a method that message to be received by the CPU module side are all transmitted in a fixed format from a target device.

C24 starts the reception processing when data of the same arrangement as the start frame is received.

When data of the same arrangement as the final frame is received, a read request is issued to the CPU module.

Since there is no arbitrary data portion, the receive data quantity will be "0" when a read request is issued to the CPU module.

### Precautions

- Any received data prior to the start frame will be ignored.
- The receive end data quantity initially set to C24 uses the default value.

**Ex.**

When ACK is registered as the start frame, and CR+LF is registered as the final frame

## ■Reception of combination (1-C)

This is a method that the start of data transmission from a target device to the CPU module side is notified by a start frame, an arbitrary data portion of a fixed length is repeatedly transmitted from a target device after that.

After the start frame is received, the subsequent received data will be handled as arbitrary data portion.

C24 starts the reception processing when data of the same arrangement as the start frame is received.

A read request is repeatedly issued to the CPU module when an arbitrary data portion, which is equivalent to the receive end data quantity initially set to C24, is received.

### Precautions

- Any received data prior to the start frame will be ignored.
- The receive end data quantity initially set to C24 should be a data quantity for an arbitrary data (fixed length) transmitted from the target device.
- Reception processing by the receive end code initially set to C24 will not be performed. Received data of a receive end code are treated as an arbitrary data portion.

**Ex.**

## Reception with the start frame (combination 1-D, 1-E) (reception using Method 1)

This is a method that an arbitrary data portion, which is equivalent to the 'Method 1 dedicated receive end data quantity' initially set to C24, is transmitted from a target device with a start frame.

C24 starts the reception processing when data of the same arrangement as the start frame is received.

When an arbitrary data, which is equivalent to the specified 'Method 1 dedicated receive end data quantity', is received, the arbitrary data portion is stored in the receive area on the buffer memory and a read request is issued to the CPU module.

### Point

- Method 1 dedicated receive end data quantity

The receive end data quantity for data reception by using Method 1 is referred to as 'method 1 dedicated receive end data quantity'.

It can be specified with the number of word/byte of "0" or bigger (the unit depends on the word/byte units designation) for each combination of the start frame and the final frame, which specifies Method 1 (up to 4 combinations).

## Precautions

- Any received data prior to the start frame will be ignored.
- The receive end data quantity initially set to C24 is not used.
- Reception processing by the receive end code initially set to C24 will not be performed. Received data of a receive end code are treated as an arbitrary data portion.
- For reception using Method 1, set "No designation" to the final frame.

### Ex.

By specifying a user frame, in which only ACK (06H) is registered, as the start frame and also the 'method 1 dedicated receive end data quantity' for an arbitrary data portion as 0 bytes, a read request will be issued to the CPU module upon the reception of a 1-byte ACK.

### Ex.

By specifying a user frame, in which only NAK (15H) is registered, as the start frame and also the 'method 1 dedicated receive end data quantity' for an arbitrary data portion as 2 bytes, a read request will be issued to the CPU module upon the reception of NAK + 2-byte data.

## Reception without the start frame (combination 2-A, 2-B) (reception using Method 0)

### ■Reception of combination (2-A)

This is a method that a user frame is used as the final frame in place of the end code for nonprocedural protocol data reception and transmitted from a target device with an arbitrary data portion.

C24 starts the reception processing when the arbitrary data portion is received.

When data of the same arrangement as the final frame is received, the arbitrary data is stored in the receive area on the buffer memory and a read request is issued to the CPU module.

### Precautions

- Any received data prior to the final frame will be all treated as an arbitrary data portion.
- The receive end data quantity initially set to C24 should be a data quantity that exceeds the size of the arbitrary data to be received.
- C24 performs the following processing with respect to the received data that is the same as the receive end code initially set to C24.

When it is included in the arbitrary data portion: C24 performs the reception processing by the receive end code.

When it is included in the final frame: C24 does not perform the reception processing by the receive end code.

#### Ex.

By registering ETX + CR + LF as the final frame, a read request is issued to the CPU module when the end of the received data receives a message of ETX + CR + LF.

### ■Reception of combination (2-B)

This is a method that a user frame is used as the final frame in place of the end code for nonprocedural protocol data reception and data in a fixed format is transmitted from a target device.

C24 issues a read request to the CPU module when data of the same arrangement as the final frame is received.

Upon data reception of this combination which contains no arbitrary data portion, the receive data quantity will be "0" when a read request is issued to the CPU module.

### Precautions

- Any received data prior to the final frame will be all treated as an arbitrary data portion.
- The receive end data quantity initially set to C24 uses the default value.
- When received data that is the same as the receive end code initially set to C24 is included in the final frame, C24 does not perform the reception processing by the receive end code.

#### Ex.

By registering ACK + CR + LF as the final frame, a read request is issued to the CPU module when the end of the received data receives a message of ACK + CR + LF.

## Remarks

The following shows the difference between the reception methods (Method 0 and Method 1) in regard to how to treat the received data when data in combination of (a start frame + and arbitrary data portion) is received.

### ■When data is received using Method 0 (combination (1-C))

- C24 regards all arbitrary data portions as valid data after a start frame has been received, and stores it sequentially in the receive area.
- C24 issues a read request to the CPU module each time arbitrary data portions, which are equivalent to the receive end data quantity, are received, and repeats this process.

### ■When data is received using Method 1 (combination (1-D, 1-E))

- C24 regards arbitrary data portions, which are equivalent to the 'method 1 dedicated receive end data quantity' specified for combination of the received start frames, as valid data after a start frame has been received, and stores it in the receive area. It then issues a read request to the CPU module.
- Any received data after data, which is equivalent to the 'method 1 dedicated receive end data quantity', has been received up to the next start frame will be ignored. (Data will not be stored in the receive area.)

## Timing for start/completion of data reception

This section explains the reading of received data based on the user frame and other factors (such as the receive end code and receive end data quantity) during data reception using a user frame.

### Timing for start/completion of data reception

The following describes the timing for start/completion of the data reception processing with C24.

- Data reception using a user frame
- Data reception using the receive end code and receive end data quantity initially set in C24
- Data reception using 'method 1 dedicated receive end data quantity'

| Type                      | Setting of the receive user frame | When using Method 0                                                                                                                                                                                                                                                                                                                                                                               | When using Method 1                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data reception start      | With a start frame                | When the start frame is received.                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                           | Without a start frame             | When the first data of arbitrary data is received.                                                                                                                                                                                                                                                                                                                                                | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Data reception completion | —                                 | The factors of data reception completion (timing of reading received data to the CPU module) is one of the following:<br>(Depends on the conditions of the prior settings.  Page 317 Timing chart for reception processing of C24)                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                           |                                   | <ul style="list-style-type: none"> <li>• When the final frame is received.</li> <li>• When data of the receive end code is received. (In the case of a combination without the start frame)</li> <li>• When data which is equivalent to the receive end data quantity is received.</li> <li>• When a reception error (time out for the no-reception monitoring time (timer 0)) occurs.</li> </ul> | <ul style="list-style-type: none"> <li>• When the start frame is received while "0" is specified for the 'method 1 dedicated receive end data quantity'.</li> <li>• When data which is equivalent to the 'method 1 dedicated receive end data quantity' is received while "1" or more is specified for the 'method 1 dedicated receive end data quantity'.</li> <li>• When a reception error (time out for the no-reception monitoring time (timer 0)) occurs.</li> </ul> |
|                           |                                   | Arbitrary data portion up to the reception of any listed above or the occurrence of a reception error is stored in the receive area in the buffer memory.                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Timing chart for reception processing of C24

The charts indicating the timing of the reception processing for data reception using a user frame, including the reception processing by the receive end data quantity, are shown below.

The numbers in the table indicate the timing of a received data read request to the CPU module.

| Combination                         |                   | Amount of received data of arbitrary data                              | Timing pattern number                                   |                                |     |                                                        |        |                                |        |                                                            |
|-------------------------------------|-------------------|------------------------------------------------------------------------|---------------------------------------------------------|--------------------------------|-----|--------------------------------------------------------|--------|--------------------------------|--------|------------------------------------------------------------|
|                                     |                   |                                                                        | Received data                                           |                                |     |                                                        |        |                                |        |                                                            |
|                                     |                   |                                                                        | Received data prior to the reception of the start frame | When receiving the start frame |     | When receiving arbitrary data in the reception message |        | When receiving the final frame |        | When receiving the end code <sup>*1</sup>                  |

|                                     |                   | Receive data quantity ≥ Receive end data quantity                      |                                                         |                                |     | Data reception on start                                | 2-A(2) |                                | 2-A(4) |                                                            |
|                                     | 2-B <sup>*2</sup> | Receive data quantity = 0                                              |                                                         |                                |     | —                                                      |        | Data reception start           | 2-B    | —                                                          |

\*1 The reception processing by the receive end code is not performed when the same data as the receive end code has been registered in the final frame.

\*2 The data reception interval is not monitored with the no-reception monitoring time (timer 0) when only the final frame is set.

### Point

When a reception error is detected, C24 stores arbitrary data portion of the data received immediately before the error in the receive area on the buffer memory, then turns the 'CH1 reception abnormal detection' (X4) ON.

## ■Combination with the start frame (Timing patterns for data reception start and data reception complete (read))

(For data reception with format-0)

(For data reception with format-1)

### Point

When data is received using Method 1, C24 checks again whether the start frame has been received after receiving data equaling the 'method 1 dedicated receive end data quantity'. Reception data during that time is ignored.

■Combination without the start frame (Timing patterns for data reception start and data reception complete (read))

# Reception procedure

The following shows the reception procedure when a message, including data with the same arrangement as the specified user frame, is received and the arbitrary data is read to the CPU module.

## Procedure

(When the CH1 side interface of C24 receives data)

- ➊ Read the user frame setting number received from the target device (□-th) out of the start frame number and final frame number (up to 4 combinations) initially set in the user frame specification for receiving area on the buffer memory from the 'Receive user frame (nth)' (Un\G603).
- ➋ Read arbitrary data portion in the reception message from the receive area (Un\G1536 to 2047 (default))

\*1 For received data using a user frame and the timing of reading the received data to the CPU module, refer to the timing for start/ completion of data reception ( Page 310 Receive data, Page 316 Timing for start/completion of data reception)

\*2 The receive user frame registration number and others should have been set with Engineering tool.  
At the time of debugging, the initial setting value for data reception shall be set prior to data reception, but after debugging is completed, it shall be set to the startup of C24. ( Page 321 Setting of receive user frames)

\*3 Reading (➊) for the CPU module to check which user frame was received by C24 and reading of the received data (➋).

## Setting of receive user frames

### Setting of the receive user frame

This setting is to receive data from a target data using the nonprocedural protocol with a user frame.

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ Module Name ⇒ [Module Parameter] ⇒ "Application Settings" ⇒ "User frame specification"

| Setting item                                 |            | Description of setting value                                                                                                                                                                                                                                                                                  |                                                                                                     |

| Start frame No. designation                  | 1st to 4th | Designate the user frame No. ('0' or '1' or higher).                                                                                                                                                                                                                                                          | Designate the user frame No. ('1' or higher).                                                       |
| Final frame No. designation                  | 1st to 4th | Designate the user frame No. ('0' or '1' or higher).                                                                                                                                                                                                                                                          | Designate '0H' for all.                                                                             |
| User frame receiving method designation      | 1st to 4th | Designate "Method 0".                                                                                                                                                                                                                                                                                         | Designate "Method 1".                                                                               |
| Method 1 dedicated receive end data quantity | 1st to 4th | The specified value is invalid.                                                                                                                                                                                                                                                                               | Designate the data quantity for the arbitrary data to be received.                                  |

## Examples of registering a receive user frame

The following are examples of pre-registering a receive user frame on the CH1 side with Engineering tool.

### ■When the start frame is specified

In the example, the following three combinations are registered for the receive user frame.

- Setting conditions

| User frame      |                             | User frame receiving method designation | Method 1 dedicated receive end data quantity | Remarks                                                     |
|-----------------|-----------------------------|-----------------------------------------|----------------------------------------------|-------------------------------------------------------------|
| 1st combination | (Start frame + Final frame) | Method 0                                | —                                            | The receive end data quantity becomes valid.                |
| 2nd combination | (Start frame only)          | Method 1                                | 0H                                           | Method 1 dedicated receive end data quantity becomes valid. |
| 3rd combination | (Start frame only)          | Method 1                                | 2H                                           |                                                             |

- Setting value

| Setting item                                                                        |     | Setting value | Remarks                                                                                                  |

## ■When the start frame is not specified

In the example, the following three combinations are registered for the receive user frame.

### • Setting conditions

| User frame      |                    | User frame receiving method designation | Method 1 dedicated receive end data quantity | Remarks                                      |
|-----------------|--------------------|-----------------------------------------|----------------------------------------------|----------------------------------------------|
| 1st combination | (Final frame only) | Method 0                                | —                                            | The receive end data quantity becomes valid. |
| 2nd combination | (Final frame only) |                                         |                                              |                                              |
| 3rd combination | (Final frame only) |                                         |                                              |                                              |

### • Setting value

## Receive user frame setting details

The following explains the purpose and designated value/stored value of each setting data for data reception using a user frame.

### ■ User frame use enable/disable designation (Un\G173/333)

Designate "Use" when using user frames to receive data.

- Write '1' in the user frame use enable/disable designation area.
- After the preparation for receiving data using the user frames is completed, '2' is written in the user frame use enable/disable designation area. (Set by C24)
- After the value in the user frame use enable/disable designation area is changed from '1' to '2', start receiving data used by the user frame.

Until '2' is written in the user frame use enable/disable designation area, data transmission cannot be started.

## ■Start frame No. designation area and final frame No. designation area (Un\G174 to 181/334 to 341)

From among the user frames registered in C24, designate the user frame No. to be used by following the designation method as shown below.

- 0H (0): No designation
- 1H to 3E7H (1 to 999): Designate the default registration frame (for OS ROM registration).
- 3E8H to 4AFH (1000 to 1199): Designate the user frame (for flash ROM registration).
- 8001H to 801FH (-32767 to -32737): Designate the user frame (for buffer memory registration).

### Precautions

- For the receive user frames, the start frame and final frame are set as a pair, regardless of whether the target device transmits these frames.  
(If the target device does not transmit either one of the frames, set the frame No. that is not transmitted to "0" (No designation).)
- A maximum of four combinations of start and final frames can be set for the nonprocedural protocol.  
However, if there is a combination that specifies the start frame when multiple combinations are set, specify the start frame for all other combinations.  
In addition, set in the following order starting from the first buffer memory.  
When specifying the start frame  
Each frame number for combinations that specify the start frame and the final frame  
Each frame number for combinations that specify the start frame but not the final frame  
When setting multiple combinations  
For the combination that specifies only the final frame without specifying the start frame, the start frame for all of the combinations cannot be specified. Set the frame number for the final frame to be used from the first buffer memory in order.
- When setting more than one combination, the start frame having the registered code in the same arrangement or the same frame No. cannot be designated.
- Use the user frame No. of the following user frames to set the receive user frames.  
Default registration frame No.: 1H to 3E7H  
User frame No. registered in C24 flash ROM: 3E8H to 4AFH  
User frame No. registered in C24 buffer memory: 8001H to 801FH
- Do not set the frame number of a user frame contains the additional code data by the transparent code for receiving specification as a user frame for data reception using the nonprocedural protocol.

■User frame receiving method designation (Un\G8224 to 8227/8480 to 8483)

In data reception using a user frame, designate the reception method for each combination of receive user frames. This setting is valid when the setting is configured in a combination that specifies a start frame. ( Page 325 Start frame No. designation area and final frame No. designation area (Un\G174 to 181/334 to 341))

Point

For combinations other than those with the start frame only, data reception is performed using 'Method 0' even if 'Method 1' is designated through the above reception method setting.

■Method 1 dedicated receive end data quantity designation (Un\G8228 to 8231/8484 to 8487)

- For a combination specifying Method 1 in the user frame receiving method designation, designate the arbitrary data word/byte count (size for performing a reception data read request to the CPU module) when the applicable start frame is received.
- Specify this for each combination specifying Method 1.
- Designate this within the size of the receive data storage area on the buffer memory.
- The unit of setting values is in accordance with the setting value set for word/byte units designation.

## 17.3 Program for Data Reception with User Frame

This section shows examples of the program to read the received data stored in C24 buffer memory to the CPU module, when data including the user frame is received.

### Reception program example

Data reception using a user frame in the following conditions and settings is shown below.

#### Input/output signal of C24

Install C24 in the position where the I/O signal is X/Y00 to X/Y1F.

#### C24 interface used for communication with target device

CH1 side RS-232 interface of C24

#### Parameter settings

| Setting item   |                               |                                | Setting value          |
|----------------|-------------------------------|--------------------------------|------------------------|
| Basic settings | Various control specification | Test mode setting              | —                      |
|                |                               | Communication protocol setting | Nonprocedural protocol |
|                |                               | Communication speed setting    | 19200 bps              |
|                |                               | Transmission setting           | Operation setting      |
|                |                               |                                | Data bit               |
|                |                               |                                | Parity bit             |
|                |                               |                                | Odd/even parity        |
|                |                               |                                | Stop bit               |
|                |                               |                                | Sum check code         |
|                |                               |                                | Online change          |
|                |                               |                                | Setting change         |
|                |                               |                                | Disable                |

#### Setting content of buffer memory

For other than the following items, use default values.

| Address DEC (HEX) | Name                                                          | Setting value       |
|-------------------|---------------------------------------------------------------|---------------------|
| <b>CH1</b>        |                                                               |                     |
| 173 (ADH)         | User frame use enable/disable designation                     | 1H: Use             |
| 174 (AEH)         | Start frame No. designation, 1st <sup>*1</sup>                | 3E8H <sup>*2</sup>  |
|                   |                                                               | 8001H <sup>*3</sup> |
| 175 (AFH)         | Start frame No. designation, 2nd <sup>*1</sup>                | 3E9H <sup>*2</sup>  |
|                   |                                                               | 8002H <sup>*3</sup> |
| 176 (B0H)         | Start frame No. designation, 3rd <sup>*1</sup>                | 6H                  |
| 177 (B1H)         | Start frame No. designation, 4th <sup>*1</sup>                | 15H                 |
| 178 (B2H)         | Final frame No. designation, 1st <sup>*1</sup>                | 41BH <sup>*2</sup>  |
|                   |                                                               | 8005H <sup>*3</sup> |
| 179 (B3H)         | Final frame No. designation, 2nd                              | 0H: None            |
| 180 (B4H)         | Final frame No. designation, 3rd                              | 0H: None            |
| 181 (B5H)         | Final frame No. designation, 4th                              | 0H: None            |
| 8224 (2020H)      | User frame receiving method designation, 1st                  | 0H: Method 0        |
| 8225 (2021H)      | User frame receiving method designation, 2nd                  | 1H: Method 1        |
| 8226 (2022H)      | User frame receiving method designation, 3rd                  | 1H: Method 1        |
| 8227 (2023H)      | User frame receiving method designation, 4th                  | 1H: Method 1        |
| 8229 (2025H)      | Method 1 dedicated receive end data quantity designation, 2nd | 12 words            |
| 8230 (2026H)      | Method 1 dedicated receive end data quantity designation, 3rd | 0 word              |
| 8231 (2027H)      | Method 1 dedicated receive end data quantity designation, 4th | 2 words             |

\*1 It indicates the registered contents of the user frame No. specified to the start and final frame No., respectively.

\*2 When the setting is configured with Engineering tool. (Page 328 Program example when setting with Engineering tool)

\*3 When the setting is configured by a program. (Page 331 Program example when setting by a program)

## ■Registration contents in user frame

| User frame No. | Registered code         | Registered data content                       |
|----------------|-------------------------|-----------------------------------------------|
| 3E8H/8001H     | 02H, 51H, 20H, 0AH, 3BH | STX, Q, (SP), Station No. of target device, ; |
| 3E9H/8002H     | 02H, 41H, 3BH           | STX, A, ;                                     |
| 6H             | 06H                     | ACK                                           |
| 15H            | 15H                     | NAK                                           |
| 41BH/8005H     | 03H, FFH, F0H           | ETX, Sum check code                           |

## Program example when setting with Engineering tool

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Read the combinations of user frames received.  
Set the reception channel to CH1.  
Set the allowable number of data to be received to 20.  
Specify the execution instruction.
- (14) Execute reception
- (60) Set normal completion flag.
- (62) Set abnormal completion flag.

## Program example when setting by a program

# Application program for data reception using a combination that specifies the start frame

The following shows the program example when receiving data using a combination that specifies the start frame.

## Reception program example

Data reception using a user frame set with the following conditions is shown below.

### ■C24 interface used for communication with target device

CH1 side RS-232 interface of C24

### ■Parameter settings

For other than the following items, use default values.

| Item                                                         | Setting content           | Buffer memory address to store registration value | Remarks                                                                      |
|--------------------------------------------------------------|---------------------------|---------------------------------------------------|------------------------------------------------------------------------------|
| Word/byte units designation                                  | Word/byte                 | 150 (96H)                                         | Set to either one according to the program example.                          |
| Transparent code for receiving specification                 | Designated/No designation | 288 (120H)                                        | When 'Designated', Additional code: 10H (DLE)<br>Transparent code: 02H (STX) |
| ASCII-BIN conversion designation                             | Do not convert            | 289 (121H)                                        | —                                                                            |
| Receive end data quantity                                    | 6                         | 164 (A4H)                                         | —                                                                            |
| Receive end code                                             | No designation            | 165 (A5H)                                         | —                                                                            |
| User frame use enable/disable designation                    | Use                       | 173 (ADH)                                         | Refer to the illustrations provided in this section.                         |
| Start frame No. designation<br>Final frame No. designation*1 | Designated                | 174 to 177 (AEH to B5H)                           |                                                                              |
| User frame receiving method designation                      | Method 0/Method 1         | 8224 to 8227 (2020H to 2023H)                     |                                                                              |
| Method 1 dedicated receive end data quantity designation     | 0H to FFFFH               | 8228 to 8231 (2024H to 2027H)                     |                                                                              |

\*1 It indicates the registered contents of the user frame No. specified to the start and final frame No., respectively.

### ■Registration contents in user frame

| Item            |     | User frame No. | Registered code         | Registered data content                       |
|-----------------|-----|----------------|-------------------------|-----------------------------------------------|
| Start frame No. | 1st | 3E8H           | 02H, 51H, 20H, 0AH, 3BH | STX, Q, (SP), Station No. of target device, ; |
|                 | 2nd | 3E9H           | 02H, 41H, 3BH           | STX, A, ;                                     |
|                 | 3rd | 6H             | 06H                     | ACK                                           |
|                 | 4th | 15H            | 15H                     | NAK                                           |
| Final frame No. | 1st | 41BH/8005H     | 03H, FFH, F0H           | ETX, Sum check code                           |
|                 | 2nd | 0H (none)      | —                       | —                                             |
|                 | 3rd | 0H (none)      | —                       | —                                             |
|                 | 4th | 0H (none)      | —                       | —                                             |

## Program example

The following shows example of data reception with a user frame.

| Category            | Label name/FB name                           | Description                      | Device                      |

| FB                  | M+RJ71C24_Input                              | Reads the received data.         | —                           |

For information on the module FB to be used, refer to the following manual.

 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Read the combinations of user frames received.  
Set the reception channel to CH1.  
Set the allowable number of data to be received to 6.  
Specify the execution instruction.
- (14) Execute reception
- (60) Set normal completion flag.
- (62) Set abnormal completion flag.

## Operation example of various combinations

### ■When receiving with a combination of the start frame, arbitrary data and final frame (reception using Method 0)

## ■When receiving with a combination of the start frame and arbitrary data (reception using Method 0)

## ■When receiving with user frame only (reception using Method 0)

Since there is no arbitrary data portion, the receive data count is [0].

The following diagram is for reception using the combination of first frame and last frame.

|          |                      |                                                        |
|----------|----------------------|--------------------------------------------------------|
| Un\G173  | 2H                   | User frame use enable/disable designation              |
| Un\G174  | 3E8H                 | First frame No. designation (1st)                      |
| Un\G175  | 3E9H                 | (2nd)                                                  |
| Un\G176  | 6H                   | (3rd)                                                  |
| Un\G177  | 15H                  | (4th)                                                  |
| Un\G178  | 41BH                 | Last frame No. designation (1st)                       |
| Un\G179  | (None) 0H            | (2nd)                                                  |
| Un\G180  | (None) 0H            | (3rd)                                                  |

Buffer memory

■When receiving with first start only (reception using Method 1)

# ■When receiving with a combination of the start frame and arbitrary data (method 1 dedicated receive end data quantity) (reception using Method 1)

# Application program for data reception using a combination that does not specify the start frame

The following shows the program example when receiving data using a combination that does not specify the start frame.

## Reception program example

Data reception using a user frame set with the following conditions is shown below.

### ■C24 interface used for communication with target device

CH1 side RS-232 interface of C24

### ■Parameter settings

For other than the following items, use default values.

| Item                                                     | Setting content | Buffer memory address to store registration value | Remarks                                                                     |
|----------------------------------------------------------|-----------------|---------------------------------------------------|-----------------------------------------------------------------------------|
| Word/byte units designation                              | Word/byte       | 150 (96H)                                         | The unit is set to "Word" in the example.                                   |
| Transparent code for receiving specification             | Designated      | 288 (120H)                                        | Specify as follows: Additional code: 10H (DLE), Transparent code: 02H (STX) |
| ASCII-BIN conversion designation                         | Do not convert  | 289 (121H)                                        | —                                                                           |
| Receive end data quantity                                | 6               | 164 (A4H)                                         | —                                                                           |
| Receive end code                                         | No designation  | 165 (A5H)                                         | —                                                                           |
| User frame use enable/disable designation                | Use             | 173 (ADH)                                         |                                                                             |
| Start frame No. designation <sup>*1</sup>                | No designation  | 174 to 177 (AEH to B1H)                           |                                                                             |
| Final frame No. designation <sup>*1</sup>                | Designated      | 178 to 181 (B2H to B5H)                           |                                                                             |
| User frame receiving method designation                  | Method 0        | 8224 to 8227 (2020H to 2023H)                     |                                                                             |
| Method 1 dedicated receive end data quantity designation | 0H              | 8228 to 8231 (2024H to 2027H)                     |                                                                             |

<sup>\*1</sup> It indicates the registered contents of the user frame No. specified to the start and final frame No., respectively.

### ■Registration contents in user frame

| Item            |     | User frame No. | Registered code | Registered data content |
|-----------------|-----|----------------|-----------------|-------------------------|
| Start frame No. | 1st | 0H (none)      | —               | —                       |
|                 | 2nd | 0H (none)      | —               | —                       |
|                 | 3rd | 0H (none)      | —               | —                       |
|                 | 4th | 0H (none)      | —               | —                       |
| Final frame No. | 1st | 419H           | 3BH, 04H        | ;; E0T                  |
|                 | 2nd | 0H (none)      | —               | —                       |
|                 | 3rd | 0H (none)      | —               | —                       |
|                 | 4th | 0H (none)      | —               | —                       |

## Program example

The following shows the example of data reception with a user frame.

| Category            | Label name/FB name                           | Description                      | Device                      |
|---------------------|----------------------------------------------|----------------------------------|-----------------------------|
| Module label        | C24_1                                        | Target module                    | —                           |
|                     | C24_1.stnCH1.bSet_Req_ReceptionRead          | CH1 Reception data read request  | X3                          |
|                     | C24_1.stnCH1.bSts_ReceptionAbnormalDetection | CH1 Reception abnormal detection | X4                          |
|                     | C24_1.stnCH1.uResult_ReceiveUserFrame_D      | CH1_Receive user frame (nth)     | U0\G603                     |
| Label to be defined | Define the global label as shown below.      |                                  |                             |
|                     | Label Name                                   | Data Type                        | Class Assign (Device/Label) |
|                     | 1 bINPUTInstructionNormalCompleteFlag        | Bit                              | VAR_GLOBAL M100             |
|                     | 2 bINPUTInstructionAbnormalCompleteFlag      | Bit                              | VAR_GLOBAL M101             |
|                     | 3 wReceptionUserFramesPairingNumber          | Word (Signed)                    | VAR_GLOBAL D100             |
|                     | 4 bINPUTInstructionExecutionCompleteDevice   | Bit                              | VAR_GLOBAL M0               |
|                     | 5 bINPUTInstructionAbnormalCompleteDevice    | Bit                              | VAR_GLOBAL M1               |
|                     | 6 bINPUTInstructionExecutionStatusDevice     | Bit                              | VAR_GLOBAL M2               |
|                     | 7 bINPUTInstructionExecutionRequestDevice    | Bit                              | VAR_GLOBAL M10              |
|                     | 8 wReceptionChannelNumber                    | Word (Signed)                    | VAR_GLOBAL D1               |
|                     | 9 wReceptionResult                           | Word (Signed)                    | VAR_GLOBAL D2               |
|                     | 10 wReceptionDataCount                       | Word (Signed)                    | VAR_GLOBAL D3               |
|                     | 11 wReceptionDataAllowableCount              | Word (Signed)                    | VAR_GLOBAL D4               |
|                     | 12 wnReceptionData                           | Word (Signed)[0..15]             | VAR_GLOBAL D10              |
| FB                  | M+RJ71C24_Input                              | Reads the received data.         | —                           |

For information on the module FB to be used, refer to the following manual.

 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Read the combinations of user frames received.  
Set the reception channel to CH1.  
Set the allowable number of data to be received to 6.  
Specify the execution instruction.
- (14) Execute reception
- (60) Set normal completion flag.
- (62) Set abnormal completion flag.

Operation example

■When receiving data using a combination of arbitrary data and final frame (reception using Method 0)

## 17.4 Data Transmission

This section explains the arrangement of the data to be transmitted and transmission procedure when transmitting data using a user frame.

### Send data

The order of data, codes, and handling of send data by C24 for data transmission using a user frame are shown below.

#### Send data arrangement

The combination shown below are only allowed as the order of data to be transmitted using a user frame.

\*1 0H to FH data for four bits are converted to 30H to 39H and 41H to 46H ASCII code data and transmitted as the data codes of the data to be transmitted (including the transparent code data).

\*2 Arbitrary data portion of send data

- When the send data quantity designated by the CPU module during transmission in byte units is an odd number of bytes, the data of the lower byte of the last transmitted data storage location in the send data storage area is transmitted.
- When ASCII-BIN conversion is enabled, the data to be transmitted is transmitted as 2 characters per byte.

#### Point

##### Handling of send data by C24

- The data of the user frame and the data in the send area designated from the CPU module is transmitted in accordance with the contents and order designated to the send user frame designation area in the buffer memory.
- For the user frame portion and arbitrary data portion, the data can be transmitted as ASCII code data using the ASCII-BIN conversion. (☞ Page 379 COMMUNICATING WITH ASCII CODE (ASCII-BIN CONVERSION))
- If a transparent code for sending is specified, the additional code data is added in front of the transparent code/additional code in the data of the designated area and transmitted.

# Transmission procedure

The following describes the transmission procedure when a message containing user frames is transmitted to the target device.

## Procedure

- \*1 Designate the user frame number for the data to be sent.
- \*2 CPU module processing
  - Before issuing a transmission request to C24, designate (write) the following data.
    - Send user frame designation area : User frame number, transmission method and transmission order registered in C24
    - Send area (Buffer memory): User data corresponding to arbitrary data portion in the transmission message
- \*3 When a send data quantity designation error or data transmission error occurred, C24 stores the error code to the transmission result storage area of control data for PRR instruction, and the status display device at completion turns ON.

## Settings of send user frames

These settings are required for transmitting data to a target device using user frames by the nonprocedural protocol. These settings are configured with Engineering tool or from the CPU module.

### Settings with Engineering tool

- Configure the settings to transmit data in "Send user frame designation" of the parameter.

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ Module Name ⇒ [Module Parameter] ⇒ "Application Settings" ⇒ "User frame specification"

### Settings by the CPU module

#### How to designate and write send data when transmitting with user frames

For arbitrary data portion when transmitting user frames and arbitrary data portion in combination, the send data quantity and send data are written in the send area as is the case in transmitting them in an arbitrary format.

User frames are registered using Engineering tool. Or, the user frame registration number to be sent is written from the CPU module to the send user frame designation area of the buffer memory as shown in the figure below.

After executing registration/write, C24 transmits the designated data in the designated order upon execution of the PRR instruction.

**Ex.**

Sending data in the following order

| Transmission order | Send data type | User frame No. | Contents of transmitted/registered data          |
|--------------------|----------------|----------------|--------------------------------------------------|
| 1                  | User frame     | 2H (2)         | 02H (STX)                                        |
| 2                  | User frame     | 3E8H (1000)    | 01H, 3BH (station No., ";")                      |
| 3                  | Arbitrary data | 8000H (-32768) | 41H, 42H, 43H, 44H ("ABCD")                      |
| 4                  | User frame     | 400H (1024)    | 03H, FFH, F6H, 0DH, 0AH (ETX, Sum check, CR, LF) |

(When the ASCII-BIN conversion is not performed)

| User frame              | Arbitrary data   | User frame         |
|-------------------------|------------------|--------------------|
| (1st)                   |                  | (4th)              |
| STX                     | Station No. (,;) | ETX                |
| 02H                     | A B C D          | Sum check code     |
| 01H, 3BH                |                  | C R F              |
| 41H, 42H, 43H, 44H      |                  | 03H, 4BH, 0DH, 0AH |
| 2H                      |                  | 400H               |
| 3E8H                    |                  |                    |
| 8000H                   |                  |                    |
| Corresponding frame No. |                  |                    |

Figure at left is for byte units.

For word units, the arbitrary data portion is sent in the sequence of "ABCD".

\*1 When transmitting data that is written in the send area, use 8000H as a temporary user frame No. (Page 348 Send user frame designation)

## ■ Send user frame designation

The following explains the purpose of the buffer memory to be used when transmitting data using user frames, along with the designated and stored values.

- 'Sending user frame' (Un\G182/342)

In data communications using a user frame, what number of the send frame number designation area is being sent is stored.

- 'CR/LF output designation' (Un\G183/343)

When transmitting a user frame or arbitrary data that does not contain CR/LF, designate whether or not a CR+LF will be sent each time a user frame or arbitrary data is sent.

- 'Output start pointer designation' (Un\G184/344)

Write the head position (□th) in the send frame number designation area for writing the registration number of the user frame to be sent.

However, transmission using a user frame is not performed when the value of the output start pointer designation area is "0".

- 'Output quantity designation' (Un\G185/345)

Write how many user frames are transmitted from the designated position in the output start pointer designation area.

However, transmission is not performed and completed normally when the value of the output quantity designation area is "0".

- 'Send frame number designation' (Un\G186 to 285/346 to 445)

Write the user frame No. to be sent in the order in which they are output from the position designated in the output start pointer designation area.

When transmitting data that is written in the send area, use 8000H as a temporary user frame No.

By designating user frame No. 8000H, C24 transmits the data in the send data specification area for the data quantity designated in the send data quantity designation area.

Specifies the following user frame No. for the data to be sent.

Note that the number on the right side of the user frame No. below is the number used for transmission without ASCII-BIN

conversion for only the data of any frame portion when transmission data is converted into ASCII-binary data and transmitted.

0H: No transmission designation. (No additional transmission is allowed.)

1H to 3E7H/4001H to 43E7H: Transmits the default frame having the designated number.

3E8H to 4AFH/43E8H to 44AFH: Transmits the user frame having the designated number. (For flash ROM registration)

8000H/C000H: Transmits data in the transmission area of the buffer memory.

8001H to 801FH/C001H to C01FH: Transmits the user frame having the designated number. (For buffer memory registration)

### Point

The following transmission can be performed by adding 4000H to the registered user frame number and specifying it.

- When ASCII-BIN conversion is enabled, a specified frame can be sent without the conversion. (☞ Page 380 ASCII-BIN Conversion for Data Communicated with Nonprocedural Protocol)
- A specified frame can be transmitted without adding the additional code by the transparent code for sending specification. (☞ Page 360 Handling Transparent and Additional Codes for Nonprocedural Protocol Data Communication)

# 17.5 Application Program for Data Transmission using a Combination that does not Specify the Start Frame

The following shows the program examples for data transmission using a user frame.

## Transmission program example

Data transmission using user frames in the following conditions and settings is shown below:

### ■C24 interface used for communication with a target device

CH1 RS-232 interface of C24

### ■Parameter settings

| Setting item   |                               |                                                    | Setting value          |

## Program example when setting using Engineering tool

The following shows the method to send data by specifying the send frame number with Engineering tool.

### Program example

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Description                                                                                                                                                  | Device     |                       |            |           |       |                       |   |                        |     |            |     |   |                                   |     |            |      |   |                                     |     |            |      |   |                   |     |            |     |   |                        |                                     |            |    |   |                    |                                           |            |    |   |                                        |     |            |    |   |                                       |     |            |    |   |                                      |     |            |    |    |                                       |     |            |     |    |                     |                                     |            |     |    |                      |               |            |     |    |                          |               |            |     |    |                      |               |            |     |    |              |               |            |     |

For information on the module FB to be used, refer to the following manual.

 MELSEC iQ-R Serial Communication Module Function Block Reference

- (3) Set the transmission channel to 1.  
Set CR/LF to "Do not send".  
Set the send pointer to 1.  
Set the output quantity to 5.  
Set an arbitrary send data quantity.  
Set an arbitrary send data.  
Set an arbitrary send data in send area.  
Set the transmission direction.
- (86) Set normal completion flag.
- (88) Set abnormal completion flag.

## Program example when not setting with Engineering tool

The following shows the methods to transmit data without specifying the send frame number with Engineering tool.

### ■Program example

# 18 TRANSPARENT CODES AND ADDITIONAL CODES

Transparent codes and additional codes are used during data communication with a target device to send/receive one-byte data for transmission control on the target device side as arbitrary data.

Transparent codes and additional codes are handled in data communication using the nonprocedural or bidirectional protocol.

| Type             | Description                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 18.1 Handling Transparent Code and Additional Code Data

The following explains how C24 handles transparent codes and additional codes during data communication using the nonprocedural or bidirectional protocol.

For the range of additional code data that is added or deleted, refer to the following sections.

- ☞ Page 360 Handling Transparent and Additional Codes for Nonprocedural Protocol Data Communication
- ☞ Page 371 Handling Transparent and Additional Codes for Bidirectional Protocol Data Communication

### At the time of data transmission

Additional code data is added immediately before the transparent code and additional code data set for transmission.

Ex.

### At the time of data reception

When additional code data set for reception is detected, the additional code data is removed and the immediately succeeding 1-byte data is processed for reception.

Ex.

## During data communication using the ASCII-BIN conversion

When transmitting data, the transparent code check is performed to the data after ASCII-BIN conversion. If a transparent code is detected, an additional code is added to the 1-byte immediately preceding it.

When receiving data, the additional code check is performed to the data before ASCII-BIN conversion. If an additional code is detected, the additional code are deleted.

Data which will be subject for the handling of a transparent code and an additional code is data after ASCII-BIN conversion for data transmission and data before ASCII-BIN conversion for data reception.

### Ex.

When transmitting/receiving data using an arbitrary format of the nonprocedural protocol

## 18.2 Registering Transparent Codes and Additional Codes

To control transparent codes and additional codes for data to be sent/received with the nonprocedural or bidirectional protocol, configuring the settings to C24 prior to data communication is required.

### Registration method

For each interface, 10 combinations and one combination of transparent codes and additional codes can be set for transmission and reception, respectively.

Transparent codes and additional codes are set in "Transparent code designation\_Transparent code for sending specification (nth)", and "Transparent code designation\_Transparent code for receiving specification" of the parameter.

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

When specifying a transparent code for sending, set it by left justifying from the transparent code for sending specification (1st) in order.

### Precautions

If additional code data is received during data reception, C24 will not treat the immediately succeeding one-byte data as the control data for the following frame:

- Data received as the start frame and final frame of the user frames

Therefore, do not configure the following settings. (The code for the data described above cannot be designated as additional codes for data reception.)

- A receive user frame setting that contains an additional code data for data reception
- The same receive same code setting as the additional code data for data reception

# 18.3 Handling Transparent and Additional Codes for Nonprocedural Protocol Data Communication

This section explains how to handle the transparent codes and additional codes during data communication using the nonprocedural protocol.

## Adding/deleting data

The data designated by the additional code is added to/deleted from the data to be transmitted or received.

## Transmitted/received data range for processing

The range of transmitted/received data to which the processing of transparent codes and additional codes is performed is as shown below.

C24 performs the following processing during data transmission and reception.

### ■At the time of data reception

When an additional code set for reception is detected, C24 removes the additional code data and perform data reception processing by treating the immediately succeeding 1-byte data as a part of the received data.

### ■At the time of data transmission

When transparent code/additional code data set for transmission is detected, C24 transmits data by adding the additional code designation data immediately before it.

During data transmission using user frames, even if a transparent code or additional code has been specified in the transparent code for sending specification area, it is possible to transmit data without adding the additional code data to the user frame portion or arbitrary data portion.

When sending data without adding the additional code specified by the transparent code for sending specification, specify the user frame number using the following method.

- Specify the number obtained by adding 4000H to the registered user frame No.

When sending data in the portions designated in 4001H to 44AFH, C000H to C01FH, the data is transmitted without conversion even when the following designations are enabled.

- Designating "Enable" in the ASCII-BIN conversion designation area. (Page 380 ASCII-BIN Conversion for Data Communicated with Nonprocedural Protocol)
- Designating "Auto delete enabled" in the NULL character automatic removal designation area. (Page 441 NULL Character Removal to Send Data using Nonprocedural Protocol)

| User frame No. to be sent         | Specified No. when transmitting data without adding the additional code specified by the transparent code for sending specification (4000H added) |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 1H to 3E7H (1 to 999)             | 4001H to 43E7H (16385 to 17383)                                                                                                                   |
| 3E8H to 4AFH (1000 to 1199)       | 43E8H to 44AFH (17384 to 17583)                                                                                                                   |

## Processing order for transmitting/receiving data

The processing steps taken by C24 to transmit/receive data by the transparent code designation and ASCII-BIN conversion enabled are as shown below.

### ■Data reception in arbitrary format

- C24 deletes (removes) the additional code designation data when a transparent code for receiving is specified.
- C24 stores the arbitrary data portion in the receive area on the buffer memory.  
When ASCII-BIN conversion is designated, C24 converts it to binary code data and stores in the buffer memory.
- C24 issues a reception data read request to the CPU module when the receive end code data is stored or data equivalent to the receive end data quantity is stored during reception of an arbitrary data portion.

### ■Data transmission in arbitrary format

- C24 transmits the data to be sent (arbitrary data portion of a transmission message), which is designated by the CPU module.  
When ASCII-BIN conversion is designated, C24 converts it to ASCII code data and transmits it.
- C24 adds the additional code data immediately before the transparent code/additional code data, and transmits it when a transparent code for sending is specified.
- C24 notifies the CPU module of the transmission normal (abnormal) completion once transmission for the send data quantity has been completed.

# Ex.

When ASCII-BIN conversion is performed

## ■Data reception using user frames

- C24 checks the reception of the user frame (start frame and final frame).
- C24 deletes (removes) the additional code designation data from an arbitrary data portion when a transparent code for receiving is specified.
- C24 calculates the sum check code when a sum check code is designated in a user frame (final frame).
- C24 stores the arbitrary data portion in the receive area on the buffer memory.
- When ASCII-BIN conversion is designated, C24 converts it to binary code data and stores in the buffer memory.
- C24 issues a reception data read request to the CPU module when the receive end code/data equivalent to the receive end data quantity is stored during reception of an arbitrary data portion, or when a user frame (final frame) is received.

## ■Transmitting data using user frames

- C24 transmits data to be sent (an arbitrary data portion of a transmission message), which is designated by the user frame or CPU module, in the order specified by the user.
- When ASCII-BIN conversion is designated, C24 converts the data in the applicable range to ASCII code data and transmits it.
- In addition, it adds the additional code data immediately before the transparent code/additional code data when transmitting the data in the applicable range, and transmits it when a transparent code for sending is specified.
- C24 notifies the CPU module of the transmission normal (abnormal) completion once transmission for the send data quantity has been completed.

The figure above shows how C24 processes the data to be sent/received when the data sending/receiving function using user frame, the ASCII-BIN conversion function, and/or the data send/receive function by transparent code designation are enabled and disabled.

Use this information as a reference to select the method to send/receive data for data communication with a target device.

# 18.4 Data Communication Using Nonprocedural Protocol

This section shows examples of data communication using the nonprocedural protocol when the settings/registrations are made with Engineering tool.

# Example of data reception

## Program example

The following shows an example of storing received data in the data register.

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Description                      | Device     |            |                       |       |                       |   |                                       |     |     |            |      |   |                                         |     |     |            |      |   |                                        |     |     |            |      |   |                                      |     |     |            |       |   |                                     |     |     |            |        |   |                                       |     |     |            |        |   |                 |               |     |            |      |   |                   |               |     |            |      |   |                             |               |     |            |      |    |            |               |     |            |      |    |              |               |     |            |       |  |  |

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Set the reception channel to the CH1 side.  
Set the allowable number of data to be received.  
Set the reception direction.
- (55) Normal completion
- (57) Abnormal completion

### Reception example based on the receive end data quantity

When C24 receives data from the target device when the transparent code designation is enabled

**Ex.**

Transparent code designation: Additional code: 10H (DLE), Transparent code: 02H (STX), Receive end data quantity designation: 6-word or 12-word

When the transparent code for receiving specification is enabled, the codes for receivable data and the codes for the received data which is stored is stored in the receive area on the buffer memory are as shown below.

| Type                                                 |                  | Receivable codes | Codes stored in the receive area |
|------------------------------------------------------|------------------|------------------|----------------------------------|
| Transparent code for receiving specification portion | Additional code  | 01H to FFH       | (Delete)                         |
|                                                      | Transparent code | 00H to FFH       | 00H to FFH                       |
| Arbitrary data portion (including end code)          |                  |                  |                                  |

## Operation example of reception by the receive end code

When C24 receives data from the target device when the transparent code designation is enabled

**Ex.**

Additional code: 10H (DLE), Transparent code: 02H (STX), End code: 0D0AH (CR+LF)

When the transparent code for receiving specification is enabled, the codes for receivable data and the codes for the received data which is stored in the receive area on the buffer memory are as shown below.

| Type                                                 |                  | Receivable codes | Codes stored in the receive area |
|------------------------------------------------------|------------------|------------------|----------------------------------|
| Transparent code for receiving specification portion | Additional code  | 01H to FFH       | (Delete)                         |
|                                                      | Transparent code | 00H to FFH       | 00H to FFH                       |
| Arbitrary data portion (including end code)          |                  |                  |                                  |

## Example of data transmission

The following shows an example of data transmission.

### Transmission by transparent code for sending specification, 1st

**Ex.**

Transparent code designation: Additional code: 10H (DLE), Transparent code: 02H (STX)

### Program example

When C24 transmits data to the target device by transparent code designation (1st combination of the transparent code for sending specification is set)

| Category            | Label name/FB name                       | Description                           | Device                      |

| FB                  | M+RJ71C24_Output                         | Sends data for specified data points. | —                           |

For information on the module FB to be used, refer to the following manual.

## Transmission by 1st/2nd combinations of transparent code for sending specification

**Ex.**

Transparent code designation (1st): Additional code: 10H (DLE), Transparent code: 02H (STX)

Transparent code designation (2nd): Additional code: 10H (DLE), Transparent code: 03H (ETX)

### Program example

When C24 transmits data to the target device by transparent code designation (2nd combination of transparent code for sending specification is set.)

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                           | Device     |                       |            |           |       |                       |   |                   |     |            |       |   |                                        |     |            |      |   |                                          |     |            |      |   |                                         |     |            |      |   |                                       |     |            |       |   |                                      |     |            |        |   |                                        |     |            |        |   |                      |               |            |      |   |            |               |            |      |    |                                 |               |            |      |    |                    |                     |            |       |

For information on the module FB to be used, refer to the following manual.

MELSEC iQ-R Serial Communication Module Function Block Reference

## 18.5 Handling Transparent and Additional Codes for Bidirectional Protocol Data Communication

This section explains how to handle the transparent codes and additional codes during data communication using the bidirectional protocol.

### Adding/deleting additional code designation code

The data designated by the additional code is added to/deleted from the data to be transmitted or received.

### Data range of transmit/receive processing

The range of transmitted/received data to which processing to transmit/receive transparent codes and additional codes is performed includes data length, data portion, and error code of a message.

Head code (ENQ, ACK, NAK) and sum check code of each message are not included.

C24 performs the following processing during data transmission/reception.

#### ■At the time of request data reception

When an additional code set for reception is detected, C24 removes the additional code data and perform data reception processing by treating the immediately succeeding 1-byte data as a part of the received data during the reception of a request data.

#### ■At the time of response message transmission

When transparent code/additional code data set for transmission is detected, C24 transmits data by adding the additional code designation data immediately before it during the transmission of the response message to data reception.

#### ■At the time of request data transmission

When transparent code/additional code data set for transmission is detected, C24 transmits data by adding the additional code designation data immediately before it during data transmission.

#### ■At the time of response message reception

When an additional code set for reception is detected, C24 removes the additional code data and perform data reception processing by treating the immediately succeeding 1-byte data as a part of the received data during the reception of the response message to data transmission.

## Precautions

The additional code data to be added/deleted is not included in the data length, nor will it be subject for sum check code.

Example of request data transmission when ASCII-BIN conversion is disabled

## Processing order for transmitting/receiving data

### At the time of reception

- C24 deletes (removes) the additional code designation data from an arbitrary data portion when a transparent code for receiving is specified.
- C24 stores the arbitrary data portion in the receive area on the buffer memory.  
When ASCII-BIN conversion is designated, C24 converts it to binary code data and stores in the buffer memory.
- When the data portion for the designated data length is received, reading the received data is requested of the CPU module.

If the sum check code is set to 'Yes' in the transmission setting via an Engineering tool parameter settings, reading the received data is requested of the CPU module upon reception of the sum check code.

### At the time of transmission

- C24 adds the transmission control code to the data to be sent (arbitrary data portion of a transmission message), which is designated by the CPU module, and transmits it.  
When ASCII-BIN conversion is designated, C24 converts it to ASCII code data at first and transmits it.
- When the sum check code is set to be enabled, C24 calculates the sum check code from the transmission message and add it to the transmission message.
- C24 adds the additional code data immediately before the transparent code/additional code data in respect to arbitrary data portion, and transmits it when a transparent code for sending is specified.

The figure above shows how C24 processes the data to be transmitted/received when the ASCII-BIN conversion function, and/or the data communication function by transparent code designation are enabled and disabled.

Use this information as a reference to select the method to send/receive data for data communication with a target device.

Ex.

The following example shows the data array when data is transmitted and received. (The transmission/reception portion of the response message is omitted.)

When ASCII-BIN conversion is not performed

Ex.

When ASCII-BIN conversion is performed

## 18.6 Data Communication Using Bidirectional Protocol

This section shows examples of data communication using the bidirectional protocol when the settings/registrations are made with Engineering tool.

### Parameter settings

For details for each setting item, refer to "Parameter". (📖 Page 454 PARAMETER SETTING)

## Example of data reception

The following example shows when receiving binary data including a transparent code from a target device.

### Transparent code for receiving specification is enabled

**Ex.**

Transparent code designation: Additional code: 10H (DLE), Transparent code: 02H (STX)

### Program example

For information on the module FB to be used, refer to the following manual.

MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Set the reception channel to CH1.  
Set the allowable number of data to be received to 6.  
Set the reception direction.
- (8) Execute reception
- (54) Normal completion
- (56) Abnormal completion

When the transparent code for receiving specification is enabled, the codes for receivable arbitrary data portion and the codes for the received data which is stored in the receive area on the buffer memory are as shown below.

| Type                                                 |                  | Receivable codes | Codes stored in the receive area |
|------------------------------------------------------|------------------|------------------|----------------------------------|
| Transparent code for receiving specification portion | Additional code  | 01H to FFH       | (Delete)                         |
|                                                      | Transparent code | 00H to FFH       | 00H to FFH                       |
| Data length, data portion                            |                  |                  |                                  |

When the data length unit is in bytes and the data length is an odd byte, 00H is stored in the upper byte of the last data storage position in the receive area.

## Example of data transmission

The following example shows when transmitting binary data including a transparent code to a target device.

### Transparent code for sending specification is enabled

**Ex.**

Transparent code designation (1st): Additional code: 10H (DLE), Transparent code: 02H (STX)

Transparent code designation (2nd): Additional code: 10H (DLE), transparent code: 03H (ETX)

### Program example

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Description                           | Device     |                       |            |           |       |                       |   |                                           |     |            |    |   |                                             |     |            |    |   |                                            |     |            |    |   |                                          |     |            |     |   |                                         |     |            |      |   |                                           |     |            |      |   |                      |               |            |    |   |                        |               |            |    |   |            |               |            |      |    |                    |                     |            |     |    |                   |     |            |     |

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

# 19 COMMUNICATING WITH ASCII CODE (ASCII-BIN CONVERSION)

This chapter explains the ASCII-binary conversion in order to transmit/receive data in ASCII code to/from a target device.

## 19.1 ASCII-Binary Conversion

ASCII-BIN conversion is the data conversion function that converts all data communicated between C24 and a target device to ASCII code data.

The ASCII-BIN conversion of data to be sent/received is performed by C24 according to the parameter settings.

## 19.2 Settings for ASCII-BIN Conversion

In order to convert data to be sent/received with the nonprocedural protocol and bidirectional protocol from binary code to ASCII code, it is necessary to configure the setting for C24 before performing data communication.

The settings for ASCII-BIN conversion are as shown below:

- The ASCII-BIN conversion settings can be configured for each interface.
- To enable ASCII-BIN conversion, set "ASCII-BIN conversion designation" to "ON".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

# 19.3 ASCII-BIN Conversion for Data Communicated with Nonprocedural Protocol

This section explains the ASCII-BIN conversion of data to be communicated using the nonprocedural protocol.

## Data range of transmit/receive processing

The range of data to be sent/received to which ASCII-BIN conversion is performed is as shown below:

C24 performs the following processing when sending or receiving data.

### ■At the time of data reception

- C24 receives data of which data code is in the range of 30H to 39H ('0' to '9') and 41H to 46H ('A' to 'F') as the data within the above conversion applicable range.
- C24 regards given data portion as ASCII code, and converts it to binary code to store in the buffer memory.
- The user frame portion is received in the data format corresponding to the registration to C24.

### ■At the time of data transmission

- C24 transmits data of which data code is in the range of 30H to 39H ('0' to '9') and 41H to 46H ('A' to 'F') as the data within the above conversion applicable range.
- C24 regards data designated by the CPU module (given data portion in a transmission message) and user frame portions as binary code data, and converts to ASCII code to transmit them.

At the time of data transmission with the user frame, it is possible to transmit data without converting the data in any user frame portion or send area on the buffer memory even if "Convert" is designated in the ASCII-BIN conversion designation area.

When sending data without ASCII-BIN conversion, specify the user frame number by the method shown below.

- Specify the number obtained by adding 4000H to the registered user frame No.

When sending data in the portions designated in 4001H to 44AFH, C000H to C01FH, the data is transmitted without conversion even when the following designations are enabled.

- Specifying an additional code by the transparent code for sending specification (  Page 358 TRANSPARENT CODES AND ADDITIONAL CODES)
- Designating "Auto delete enabled" in the NULL character automatic removal designation area (  Page 441 NULL Character Removal to Send Data using Nonprocedural Protocol)

| User frame No. to be sent         | Designated No. for the user frame when transmitting without ASCII-BIN conversion (4000H added) |
|-----------------------------------|------------------------------------------------------------------------------------------------|
| 1H to 3E7H (1 to 999)             | 4001H to 43E7H (16385 to 17383)                                                                |
| 3E8H to 4AFH (1000 to 1199)       | 43E8H to 44AFH (17384 to 17583)                                                                |
| 8000H to 801FH (-32768 to -32737) | C000H to C01FH (-16384 to -16353)                                                              |

## Processing order for data transmission/reception

The processing steps taken by C24 to transmit/receive data with ASCII-BIN conversion and transparent code designation enabled are explained in the section for transparent codes and additional codes. (  Page 360 Handling Transparent and Additional Codes for Nonprocedural Protocol Data Communication)

- Data transmission/reception in arbitrary formats
- Data transmission/reception using user frames

# 19.4 Data Communication Using Nonprocedural Protocol

This section shows examples of data communication using the nonprocedural protocol when the settings/registrations are made with Engineering tool.

## Parameter settings

For details for each setting item, refer to the parameters. (  Page 454 PARAMETER SETTING)

| Setting item         |                               |                                                    | Setting content                           |                 | Remarks                   |
|----------------------|-------------------------------|----------------------------------------------------|-------------------------------------------|-----------------|---------------------------|

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Set the reception channel to CH1.  
Set the allowable number of data to be received to 6.  
Set the reception direction.
- (7) Execute reception.
- (53) Normal completion
- (55) Abnormal completion

## Operation example of reception by the receive end code

When C24 receives data from the target device when ASCII-BIN conversion is enabled (Reception by the receive end code)

**Ex.**

End code: 9H (code after ASCII-BIN conversion)

When ASCII-BIN conversion is enabled, the codes for the receivable data and the codes for the received data which is stored in the receive area on the buffer memory are as shown below.

| Type                                        | Receivable codes       | Codes stored in the receive area |
|---------------------------------------------|------------------------|----------------------------------|
| Arbitrary data portion (including end code) | 30H to 39H, 41H to 46H | 0H to 9H, AH to FH               |

If data codes other than 30H to 39H and 41H to 46H are received for an arbitrary data portion, an error (7F20H) occurs after ASCII-BIN conversion processing by C24.

To perform ASCII-BIN conversion, ensure the end code is the code after conversion.

## Operation example of reception based on the receive end data quantity

**Ex.**

When C24 receives data from the target device when ASCII-BIN conversion is enabled (Reception based on the receive end data quantity)

When the transparent code for receiving specification is disabled and ASCII-BIN conversion is enabled, the codes for the receivable data and the codes for the received data which is stored in the receive area on the buffer memory are as shown below.

| Type                                        | Receivable codes       | Codes stored in the receive area |
|---------------------------------------------|------------------------|----------------------------------|
| Arbitrary data portion (including end code) | 30H to 39H, 41H to 46H | 0H to 9H, AH to FH               |

If data codes other than 30H to 39H and 41H to 46H are received for an arbitrary data portion, an error (7F20H) occurs after ASCII-BIN conversion by C24.

# Operation example of reception using user frames

Ex.

When C24 receives data from the target device when ASCII-BIN conversion is enabled (Reception using user frames)

## Example of data transmission

The following shows an example of data transmission.

### Transmission of arbitrary data

When C24 transmits data to the target device with ASCII-BIN conversion used (Transmitting given data with OUTPUT dedicated instruction)

**Ex.**

### Program example

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                           | Device |            |                       |           |  |       |                       |   |                   |     |     |            |       |   |                      |               |     |            |      |   |                        |               |     |            |      |   |            |               |     |            |       |   |                                    |     |     |            |       |   |                                         |     |     |            |      |   |                                                |     |     |            |      |   |                                                  |     |     |            |      |   |                    |                     |     |            |       |    |                     |     |     |            |        |    |                       |     |     |            |        |

For information on the module FB to be used, refer to the following manual.

 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Set the transmission channel to CH1.  
Set CR/LF to "Do not send".  
Set the send pointer to 1.  
Set the output quantity to 5.  
Set the send data length to 2WORD.  
Set an arbitrary send data.  
Set an arbitrary transmitted data in send buffer.  
Set the data to be transmitted to user frame 8001H.  
Set the transmission direction.
- (41) Execute user frame transmission.
- (88) Normal completion
- (90) Abnormal completion

# 19.5 ASCII-BIN Conversion for Data Communicated with Bidirectional Protocol

This section explains the ASCII-BIN conversion of data to be communicated using the bidirectional protocol.

## Transmitted/received data range for ASCII-BIN conversion

The range of data to be sent/received to which ASCII-BIN conversion is performed is as shown below:

Ex.

C24 performs the following processing when sending or receiving data.

### ■At the time of data reception

Processing flow when a message is received during data reception

- C24 converts a received data length (4-digit ASCII code data (hexadecimal)) to 2-byte binary code data and stores it in the receive data quantity storage area.
- C24 converts each two characters of a received data portion (2-digit ASCII code data (hexadecimal)) to 1-byte binary code data and stores it in the receive data storage area.
- C24 calculates a sum check code using the received data length and data portion prior to ASCII-BIN conversion, then checks the head of the received sum check code using the code as a lower byte.

Processing flow when a response message is received

- C24 converts the first 2 digits of a received error code (4-digit ASCII code data (hexadecimal)) to 2-byte binary code data as the lower byte, and stores it in the transmission result storage area. (When '1234' is received, it is converted to 3412H and stored.)

### ■At the time of data transmission

Processing flow when a message is transmitted during data transmission

- C24 converts a data length (send data quantity) to 4-digit ASCII code data (hexadecimal), and sends it beginning with the lowest byte (L).
- C24 converts a data portion (send data) for one address to 4-digit ASCII code data (hexadecimal), and sends it beginning with the lowest byte (L).
- C24 calculates a sum check code using the data length and data portion after ASCII-BIN conversion, and adds it to the transmission message.

Processing flow when a response message is transmitted

- C24 converts an error code for a detected error to 4-digit ASCII code data (hexadecimal), then sends it beginning with the lowest byte (L).  
(For 3412H, it is converted to '3412' and sent beginning with '12'.)

**Ex.**

## Calculation of sum check code

## Processing order for data transmission/reception

The processing steps taken by C24 to transmit/receive data with ASCII-BIN conversion and transparent code designation enabled are explained in the section for transparent codes and additional codes. (Page 371 Handling Transparent and Additional Codes for Bidirectional Protocol Data Communication)

## 19.6 Data Communication Using Bidirectional Protocol

This section shows examples of data communication using the bidirectional protocol when the settings/registrations are made with Engineering tool.

### Parameter settings

For details for each setting item, refer to the parameter. (  Page 454 PARAMETER SETTING)

# Example of data reception

## Data reception example (ASCII-BIN conversion is enabled)

The following shows an example of data reception when ASCII-BIN conversion is enabled.

### Program example

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Description                     | Device     |            |                       |       |                       |   |                 |               |     |            |      |   |                            |               |     |            |      |   |                              |     |     |            |       |   |                                          |     |     |            |      |   |                                            |     |     |            |      |   |                                   |     |     |            |      |   |            |               |     |            |       |   |                   |               |     |            |      |   |               |                      |     |            |       |    |                     |     |     |            |        |    |                       |     |     |            |        |  |  |

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Set the reception channel to CH1.  
Set the allowable number of data to be received to 6.  
Set the reception direction.
- (6) Execute reception.
- (52) Normal completion
- (54) Abnormal completion

When ASCII-BIN conversion is enabled, the codes for receivable arbitrary data portion and the codes for the received data that is stored in the receive area on the buffer memory are as follows:

| Type                      | Receivable codes       | Codes stored in the receive area |
|---------------------------|------------------------|----------------------------------|
| Data length, data portion | 30H to 39H, 41H to 46H | 0H to 9H, AH to FH               |

# Example of data transmission

## Data transmission example (ASCII-BIN conversion is enabled)

The following shows an example of data transmission with ASCII-BIN conversion used.

Ex.

For data designated by the CPU module, data for one word is converted to 4-byte data ('0' to '9' and 'A' to 'F') and transmitted.

### Program example

| Category            | Label name/FB name                      | Description                                      | Device              |     |            |                       |

| FB                  | M+RJ71C24_BidirectionalOutput           | Sends data for specified data points.            | —                   |     |            |                       |

For information on the module FB to be used, refer to the following manual.

MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Set the transmission channel to CH1.  
Set the send data quantity to 4.  
Set arbitrary data to be transmitted in D10 to D13.  
Set the instruction execution.
- (20) Execute transmission.
- (65) Normal completion
- (67) Abnormal completion

# 20 DATA COMMUNICATIONS BETWEEN TARGET DEVICE AND CPU MODULE IN M:N BASIS

## Point

Always read this chapter when communicating data by the multidrop connection in the system configuration that the target device and CPU module are connected on an m:n basis.

This section explains data communications between the target devices and the CPU module by the multidrop connection of multiple target devices (m stations) and C24s (n stations). (The total number of 'm' and 'n' is up to 32 stations.)

With this m:n multidrop communication, only MC protocol data communications by command transmission from the target devices can be performed.

## 20.1 Considerations on Data Communications

### Concurrent data communication with multiple target devices

When communicating data in m:n system configuration, more than one target devices cannot communicate data with the CPU module at the same time.

Configure interlock among the target devices so that the target device can communicate data with the CPU module in a 1:1 basis.

For details on arrangement and method for interlock among target devices, refer to the following sections.

☞ Page 400 Arrangement for Interlock among Target Devices

☞ Page 403 Examples of Procedure for Data Communications with CPU Module

### Data communication method

Data communication between target devices and the CPU module can be performed by the following methods only:

- Data communication with the full-duplex communication method (The m:n data communications is impossible with half-duplex communications)
- Data communications by command transmission from target device using the MC protocol excluding the format 3 and format 5 control procedure (Data communications using the format 3 and format 5 control procedure and data transmission from sequence program using the on-demand function cannot be performed.)

### Data transmitted from any of target devices

Data transmitted by one target device is received by all the other target devices, including the target device that transmitted the data. The sent data from the CPU module is also received by all the target devices.

Therefore, devices that received data not addressed to their own stations (by judging by the station number in a message) are required to ignore the received data.

At the CPU module side, C24 also ignores the received data not addressed to it.

## Numbers designated for "Station No." and "Self-station No."

Designate the numbers below for "Station No." and "Self-station No." in the command message transmitted from the target device for data communications in the m:n system configuration.

### ■When accessing to C24

| Item             | Communications with 2C/3C/4C frame                          | Communications with 1C frame                          |
|------------------|-------------------------------------------------------------|-------------------------------------------------------|
| Station No.      | Station number of C24 to be passed through                  |                                                       |
| Self-station No. | Station number of access source target device <sup>*1</sup> | No designation necessary (No "Self-station No." item) |

### ■When accessing to other device (communications for interlock)

| Item             | Communications with 2C/3C/4C frame                        | Communications with 1C frame                          |
|------------------|-----------------------------------------------------------|-------------------------------------------------------|
| Station No.      | Station number of access destination device <sup>*1</sup> |                                                       |
| Self-station No. | Station number of access source device <sup>*1</sup>      | No designation necessary (No "Self-station No." item) |

<sup>\*1</sup> The number which has not been set to the respective C24s on the CPU module side is used within the range of "0" to "31" (00H to 1FH) as the number for the target device side in "Station No." and "Self-station No." in the message.

Select and designate the number of each target device.

The designation method is as shown in 'Contents of the data designation items' of each frame.

( MELSEC Communication Protocol Reference Manual)

- Station No.: Designate the number of the transmit destination device.
- Self-station No.: Designate the number of the transmit source device. (No designation necessary when 1C frame is used.)

## 20.2 Arrangement for Interlock among Target Devices

When using the multidrop connection to communicate data between target devices and the CPU module in a m:n basis, the interlocks need to be configured among the target devices to prevent more than one target devices from communicating data with the CPU module at the same time.

The arrangements necessary for providing the interlocks among the target devices in order for one of the target devices to communicate data with the CPU module are as shown below.

(Arrangements for priority use of the line (obtaining line ownership) from the start to the end of data communications with the CPU module.)

### Maximum communication time per target device station

Determine the maximum time for each target device to communicate data with the CPU module once it obtained the line ownership.

This prevents loss of data communications between other devices and the CPU module in such cases as the target device, which obtained the line ownership, went down.

Ex.

#### Restriction

- The maximum data communication time per target device station must be the maximum time required by the respective devices to communicate data with the CPU module.
- The device which obtained the line ownership must complete data communication with the CPU module within the maximum data communication time after the system started. (If data communications cannot be completed within the time, initialize the C24 transmission sequence by transmitting the EOT/CL code to the target CPU module within the maximum communication time. (MELSEC Communication Protocol Reference Manual))
- While a target device and the CPU module are communicating data, have the other devices check for timeout so that they do not transmit data during this time.

# Message structure when communicating data among target devices

Determine the message structure to communicate data among target devices by any of the following.  
This is determined to provide interlocks among the other target devices so that each of them can communicate data with CPU module on a 1:1 basis.

## Same message structure as control procedure format frame

### ■Use an unset number for "Station No." and "Self-station No." in a message.

The number which has not been set to the respective C24s on the CPU module side is used within the range of "0" to "31" (00H to 1FH) as the number for the target device side in "Station No." and "Self-station No." in the message.

### ■Select and designate the target device numbers.

The designation method is as shown in 'Contents of the data designation items' of each frame. (MELSEC Communication Protocol Reference Manual)

- Station No. : Designate the number of the transmission destination device.
- Self-station No.: Designate the number of the transmission source device. (No designation necessary when 1C frame is used.)

#### Ex.

When the m:n configuration is 5:27

The values in ( ) indicate the respective station number of the target device and C24. (decimal: hexadecimal)

The above C24 includes Q series C24, L series C24, QC24(N), and UC24.

(3C frame format 1)

| Oz  | Frame Identification No. |     | Station No. |     | Network No. |     | PC No. |     | Self-station No. |     |
|-----|--------------------------|-----|-------------|-----|-------------|-----|--------|-----|------------------|-----|
|     | H                        | L   | H           | L   | H           | L   | H      | L   | H                | L   |
|     | F                        | 9   | 1           | C   | 0           | 0   | F      | F   | 1                | B   |
| 05H | 46H                      | 39H | 31H         | 43H | 30H         | 30H | 46H    | 46H | 31H              | 42H |

Different message structure from control procedure format frame

- Change the head data of each message to other arbitrary data.
