- When format 1, format 2, or format 4 is selected for communication using ASCII code, change ENQ (05H).
- Use arbitrary data array after the head data of each message according to the user specifications.

Ex.

Point

For the message structure for general report to all of the other devices except the CPU module station, use an unused station number or a message structure different from the C24 control procedure format.

## 20.3 Examples of Procedure for Data Communications with CPU Module

This section shows examples of procedures to communicate data with the CPU module by configuring interlocks among the target devices.

### Sequential data communications between target devices and the CPU module

Each target device obtains the line ownership in turns according to the station number to communicate with the CPU module.

Ex.

Ex.

The example below shows the procedures for each target device to communicate data with the CPU module.

- ① When the system starts, the target device with the lowest station number (1BH) obtains the line ownership.
  - When format 1, format 2, or format 4 is selected for communication using ASCII code, change ENQ (05H).
- ② The target device that obtained the line ownership,
  - Begins the processing from ④ after communicating data with the CPU module within the maximum data communication time arranged among the target devices, when communicating data with the CPU module.
  - Immediately begins the processing from ④, when not communicating data with the CPU module.
- ③ The target devices that have not obtained the line ownership check the line usage time of the target device that obtained the line ownership and ignore the received data not addressed to their own station.
  - When the line usage time exceeds the maximum data communication time, each target device performs the processing of ⑦.

Ex.

④ The target device that has communicated data with the CPU module, or a target device that does not need to communicate data with the CPU module transmits the data for transferring the line ownership to the target device with the next station number. A message structure example is shown in ⑤.

When a response message (refer to ⑤ in this section) is not received from the next target device to which the line ownership is to be passed, data transmission for transferring the line ownership to the target device with the next station number is repeated until the line ownership is transferred.

⑤ The target device that receives the line ownership transmits a response message to the target device that passes it the line ownership.

Ex.

\*1 Command "ZZ" is a command for description purpose. Determine the command to transfer/obtain the line ownership at the user side.

⑥ The target device that accepted the line ownership by transmitting the response message performs the processing from ②.

⑦ When the line usage time of the target device that currently has the line ownership exceeds the maximum data communications time,

- The target device, which has the next station number, transmits all of the other devices excluding the CPU module station the general report data and obtains the line ownership and performs the processing ②.

Ex.

|                                                                  |     |                                            |                                       |         |                   |

|                                                                  | 3BH | 31H 46H                                    | 31H 43H                               | 5AH 5AH | 30H               |
|                                                                  |     |                                            |                                       |         | Sum check<br>code |
|                                                                  |     |                                            |                                       | (0A)    | 30H 41H           |

\*1 It is a station number for general report to all of the other devices.

\*2 Command "ZZ" is a command for description purpose. Determine the command to transfer/obtain the line ownership at the user side.

- The other target devices check if the general report data was received.

If the data was received, the target device performs the processing ③.

If the data was not received, the next target device transmits general report data and obtains the line ownership and performs the processing ②. The other target devices checks if the general report data has been received.

# Data communications between target devices and CPU module by designating a master station and slave stations

One of the target devices becomes the master station and the other target devices communicate data with the CPU module after obtaining permission from the master station.

Ex.

The example below shows the procedures for each target device to communicate data with the CPU module. In this example, after the start of data communications between a target device and the CPU module, each device checks for timeout of the maximum data communication time. In addition, devices on the slave station, which are not communicating data with the CPU module, check if the target device that completed data communications with the CPU module transmitted a communication complete report. In the following descriptions, the target device with the lowest station number(1BH) is the master station and the other target devices are slave stations.

Ex.

① A slave station that wants to communicate data with the CPU module sends a communications request to the master station to obtain the line ownership. A message structure example is shown in ②.

2 The master station transmits a permission response to the slave station that issued the communications request.

Ex.

3 The slave station that received the permission response performs the processing from 5 after communicating data with the CPU module within the maximum data communication time arranged among the target devices.

4 The master station that transmitted the permission response and the slave stations that does not obtain line ownership check the line usage time of the slave station that obtained the line ownership, and ignore the received data not addressed to their own station.

If the line usage time exceeds the maximum communication time, each target device performs the processing 7.

5 The slave station that has communicated data with the CPU module transmits a communication complete report to the master station after data communications completed. A message structure example is shown in 6.

Slave stations that do not communicate data with the CPU module check if a communications complete report was transmitted, and do not communicate data with the master station during that time.

⑥ The master station that received the communication complete report transmits a response to the slave station that transmitted the communication complete report.

Ex.

| Message of ⑤ *1                                                                    |                                      |                                 |         |              |                |  |                                      |                                 |  |
|------------------------------------------------------------------------------------|--------------------------------------|---------------------------------|---------|--------------|----------------|--|--------------------------------------|---------------------------------|--|
| Target device of slave station to perform the communications complete report (1CH) | Transmission destination station No. | Transmission source station No. | Command | Message wait | Sum check code |  | Transmission destination station No. | Transmission source station No. |  |
|                                                                                    | (1B)                                 | (1C)                            | (ZY)    | (2)          | (CC)           |  |                                      | (1C)                            |  |
|                                                                                    | 3BH 31H 42H                          | 31H 43H                         | 5AH 59H | 32H          | 43H 43H        |  |                                      | 31H 43H                         |  |
|                                                                                    |                                      |                                 |         |              |                |  | Message of ⑥                         |                                 |  |
| Master station target device (1BH)                                                 | Transmission destination station No. | Transmission source station No. |         |              |                |  | Transmission destination station No. | Transmission source station No. |  |
|                                                                                    | (1B)                                 | (1C)                            |         |              |                |  |                                      | (1C)                            |  |
|                                                                                    | 3AH 31H 42H                          | 31H 43H                         |         |              |                |  |                                      | 31H 43H                         |  |

⑦ After the completion of ⑥ above, or when the line usage time of the slave station that obtained the line ownership exceeds the maximum data communication time,

- The master station waits for a communication request from a slave station.  
When the master station receives a communication request, it performs processing from ②.
- The slave stations do not communicate data with the master station until data communication with the CPU module is required.

When data communications with the CPU module is required, they perform the processing from ①.

⑧ When the master station itself communicates data with the CPU module, it transmits all devices excluding the CPU module station a general report data and obtains the line ownership before communicating data with the CPU module while slave stations do not have the line ownership.

After data communications with the CPU module were completed, the master station transmits general report data to inform the slave stations that data communications with the CPU module are completed.

During this time, the slave stations do not communicate data with the master station until master station data communications have been completed.

Ex.

| *1                                                                                  |                                      |                                 |         |              |                |  |                                      |                                 |  |

|                                                                                     | (1F)                                 | (1B)                            | (ZY)    | (0)          | (08)           |  |                                      | (1C)                            |  |
|                                                                                     | 3BH 31H 46H                          | 31H 42H                         | 5AH 59H | 30H          | 30H 38H        |  |                                      | 31H 43H                         |  |

- \*1 Station No. for all target devices general report.
- \*2 Commands "ZX" and "ZY" are commands for description purposes.  
The user should select the command when the master station communicates data with slave stations.

# 21 SWITCHING THE MODE AFTER STARTING

This function forcefully switches the current communication protocol and transmission specifications of a designated interface from a target device and by program after C24 starts up.

C24 starts operating with the setting values in "Module Parameter" of Engineering tool at the time of the startup.

Point

This function is used to change the communication protocol and transmission specification of the designated interface and continue data communications without restarting the CPU module. For mode switching by using the dedicated instruction (UINI instruction) or the module FB (InitialUnit instruction), refer to the following section.

📖 Page 580 Dedicated Instructions

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

## Mode switching from target device

- Mode switching can be performed when the communication protocol of an interface connected to the target device is the MC protocol.
- The communication protocol can be changed from the MC protocol as shown below.

- The transmission specifications set with the parameter setting of Engineering tool can be changed.
- When switching the mode to MODBUS (slave function), use a C24 the firmware version of which is '13' or later.
- The mode cannot be switched to the simple CPU communication.

## Mode switching by program

- Regardless of the current communication protocol of an interface connected to the target device, mode switching can be performed by program.
- The communication protocol can be changed by program as shown below.

\*1 Change from MELSOFT connection to MELSOFT connection is not available.

- The transmission specifications set with the parameter setting of Engineering tool can be changed.
- The mode cannot be switched from/to the simple CPU communication.

### Point

When using the mode switching function, set "Setting change" of the Engineering tool parameter settings (by selecting [Basic settings] ⇒ [Various control specification] ⇒ [Transmission Setting]) to "Enable".

# 21.1 Mode Switching Operation and Contents that can be Changed

This section describes the settings that can be changed with the mode switching function and the operation of C24 after mode switching.

## Settings that can be changed with mode switching

The settings that can be changed with mode switching are as shown below.

### Switching the communication protocol

- The communication protocol setting of each interface can be switched.
- The communication protocol after mode switching is specified with the 'Switching mode No. designation' (Un\G144/304) in the area for designation of mode switching on the buffer memory.

### Switching the transmission specifications

- The transmission setting of each interface can be switched.
- The transmission setting after mode switching is specified with the 'Transmission specifications after switching designation' (Un\G145/305) in the area for designation of mode switching on the buffer memory.

With the mode switching function, the settings corresponding to "Communication protocol setting" and "Transmission setting" in the parameter settings of Engineering tool can be changed.

## Operation for mode switching

The following describes C24 operation for mode switching.

### Processing currently in execution

- When a mode switching request is issued, the mode switching process starts immediately.
- If any of the following processing is performed when a mode switching request is issued, the processing will be terminated.

| Processing in execution                                                                              | Operation for mode switching                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data communication using the MC protocol                                                             | <ul style="list-style-type: none"><li>• Receiving command messages and sending response messages or on-demand data are all terminated.</li><li>• The transmission completion signal for a transmission request of on-demand data does not turn ON.</li></ul>                                                                                                                                                                                            |
| Data communication using the nonprocedural protocol, bidirectional protocol, and predefined protocol | <ul style="list-style-type: none"><li>• Transmission processing and reception processing are all terminated.</li><li>• All input signals from a CPU module related to transmission processing and reception processing turn OFF.</li><li>• While received data from the target device was being stored to C24, the received data up to that point is ignored and the data is processed with the current receive data quantity treated as "0".</li></ul> |
| Data communication using the MODBUS slave function                                                   | Receiving command messages and sending response messages are all terminated.                                                                                                                                                                                                                                                                                                                                                                            |

### Modification of buffer memory stored value

- Special applications area (Un\G594 to 595, Un\G610 to 611)  
The communication protocol status and transmission specifications after mode switching has been completed are stored. The values stored to areas other than the above are not changed. The contents before mode switching are preserved.
- User setting area (Un\G1024 to 6911, Un\G9728 to 16383)  
The stored values are not changed. The contents before mode switching are preserved.
- User setting area for MODBUS (Un\G49152 to 53247)  
The stored values are not changed. The contents before mode switching are preserved.

## 21.2 Considerations for Mode Switching

### Modification of buffer memory stored value

Determine the following items between the target device and the CPU module to prevent mode switching during data communications.

- How to perform mode switching - from the target device or by program
- Timing for each mode switching pattern (📖 Page 411 Operation for mode switching)
- Interlocking of all connected devices for mode switching
  - Method to configure interlock when informing all of the connected stations the mode switching execution
  - Method and message structure when informing all of the connected stations the mode switching completion
  - Device number and meaning of the value when a CPU module word device is used

### Transmission specifications for each communication protocol

The transmission specifications must be changed depending on the communication protocol when switching the mode. For the transmission specifications for each communication protocol, refer to the following section.

📖 Page 456 Various control specification

### Mode switching from target device

- Once the mode has been switched to a mode other than MC protocol (Formats 1 to 5), it cannot be changed from the target device.
  - In this case, switch the mode by program.
- Mode switching from the target device can be performed to only C24 connected to a target device (including connected stations by multidrop connection).
  - It is not available for C24s on the other stations via network system. (📖 MELSEC Communication Protocol Reference Manual)

#### Point

It is recommended to perform mode switching by program.

### Mode switching of the MODBUS slave function

When switching the mode to the MODBUS slave, set values for the following buffer memories in advance.

- MODBUS device assignment parameter (Un\G30976 to 31359)
- Setting area for MODBUS (Un\G28680 to 28689)

When using a C24 the firmware version of which is '12' or earlier, mode switching to/from the MODBUS slave can be performed only by using I/O signals for handshake with a CPU module.

#### ■ Switching by using the dedicated instruction or MC protocol

When switching the mode by using the dedicated instruction (UINI) or MC protocol, use a C24 the firmware version of which is '13' or later.

### Data communications after mode switching

While the mode switching is being executed, data communications between C24 and the target device cannot be performed, including the processing time to store the setting value to the special applications area on the buffer memory.

### Mode switching related to interlink operation

Do not switch the mode when the two interfaces of C24 are in the interlink operation. Also, do not switch the mode for the interlink operation.

## 21.3 I/O Signals for Handshake with CPU Module and Buffer Memory

This section explains the I/O signals for handshake and the buffer memories used when mode switching is performed.

### I/O signals for handshake with CPU module

| Type           | I/O signal |     | Signal name            | Device turned ON/<br>OFF | Timing |
|----------------|------------|-----|------------------------|--------------------------|--------|
|                | CH1        | CH2 |                        |                          |        |
| Mode switching | X6         | XD  | Switching mode         | C24                      |        |
|                | Y2         | Y9  | Mode switching request | CPU                      |        |

#### Point

The following signals can also be used as I/O signals, in addition to the above.

- Module READY signal (X1E): Turns ON when C24 can be accessed from the CPU module.
- Watchdog timer error signal (X(n+1)F): Turns ON when C24 does not operate normally.
- 'CH1 Error occurrence' (XE): Turns ON when error occurred on the CH1 side.
- 'CH2 Error occurrence' (XF): Turns ON when error occurred on the CH2 side.

For details on the CPU module I/O signals, refer to the following section.

( Page 545 Input/Output Signal List)

| 144 (90H)              | 304 (130H) | For designation of mode switching                        | Switching mode No. designation ( Page 413 Switching mode No. designation (Un\G144/304))                                                  | 0001H: MC protocol (Format 1)<br>to<br>00FFH: MELSOFT connection                                          |
| 145 (91H)              | 305 (131H) |                                                          | Transmission specifications after switching designation( Page 414 Transmission specifications after switching designation (Un\G145/305)) | 0000H : Match the setting in MELSOFT.<br>8000H to 8FFFH: Match the setting to that of this area           |
| 515 (203H)             |            | For confirmation of parameter setting and mode switching | Parameter setting error and mode switching error status                                                                                  | 0: No error<br>Other than 0: Parameter setting error, mode switching error<br>( Page 519 Error Code List) |

#### ■Switching mode No. designation (Un\G144/304)

Designate a mode number after mode switching.

- 0000H (default): Match the setting in MELSOFT.
- 0001H: MC protocol (format 1)
- 0002H: MC protocol (format 2)
- 0003H: MC protocol (format 3)
- 0004H: MC protocol (format 4)
- 0005H: MC protocol (format 5)
- 0006H: Nonprocedural protocol
- 0007H: Bidirectional protocol
- 0009H: Predefined protocol
- 000AH: MODBUS slave (RTU)
- 000BH: MODBUS slave (ASCII)
- 00FFH: MELSOFT connection<sup>\*1</sup>

<sup>\*1</sup> Specify "00H" for the communication protocol setting when specifying the MELSOFT connection mode with the parameter settings of Engineering tool.

## ■Transmission specifications after switching designation (Un\G145/305)

Specify the transmission specifications after mode switching.

Write "0000H" when returning to the settings configured with Engineering tool.

When setting arbitrary transmission specifications (other than the transmission specification set with Engineering tool), write the value corresponding to ON/OFF of the relevant bit. The relevant bit 1 (ON)/0 (OFF) is specified as the same as the transmission setting of Engineering tool.

- For C24

|         |    |           |                       |    |             |    |             |    |                                             |    |            |

| 14400                               | 86H                       | -                                   | -                         |                                                                                                                                                               |

## Precautions

The following I/O signals for handshake and buffer memories need to be considered on the CPU module side at the time of mode switching from the target device.

- 'CH□ switching mode' (X6/XD)
- 'Parameter setting error, mode switching error status' (Un\G515)

## 21.4 Mode Switching Method by Program

This section shows how to switch the C24 mode by program.

### Mode switching procedure

The procedures for switching C24 mode by program are as shown below.

- \*1 Inform in advance all the connected device that data communications cannot be performed due to mode switching.
- \*2 When an error occurs after checking 'Parameter setting error, mode switching error status' (Un\G515), take the corresponding actions. (Page 519 Error Code List)
  - Checking of mode switching designation contents for buffer memory mode switching area and writing of mode switching designation contents within the range that can be designated
  - Re-execution of mode switching
- \*3 After confirming that mode switching was completed normally, inform all the connected devices that data communications are possible, and restart data communications.  
 To check C24 mode (communication protocol, transmission specifications) after mode switching, read the buffer memory (Un\G594 to 595/610 to 611). (Page 489 Current operation status reading method)

## Program example

The following shows an example of program for mode switching of the CH1 side interface.

| Category     | Label name                                   | Description                                          | Device  |

Label to be defined

|   | Label Name                     | Data Type                                 | Class      | Assign (Device/Label) |
|---|--------------------------------|-------------------------------------------|------------|-----------------------|
| 1 | wModeSwitchingError            | Word (Unsigned)/Bit String [16-bit]       | VAR_GLOBAL | D2                    |
| 2 | bModeSwitchingCompletion       | Bit                                       | VAR_GLOBAL | M50                   |
| 3 | bReq_ModeSwitchingRequestClear | Bit                                       | VAR_GLOBAL | X52                   |
| 4 | bReq_ModeSwitching             | Bit                                       | VAR_GLOBAL | X60                   |
| 5 | bReceivingFlag                 | Bit                                       | VAR_GLOBAL | M11                   |
| 6 | bSendingFlag                   | Bit                                       | VAR_GLOBAL | M12                   |
| 7 | wnModeSwitchingDesignation     | Word (Unsigned)/Bit String [16-bit][0..1] | VAR_GLOBAL | D0                    |

- (0) Change the operation mode to MC protocol format 1.  
Set the transmission specifications.  
Write the mode switching designation contents to the buffer memory.  
Set the mode switching request.
- (17) Reset the mode switching request signal.  
Read the mode switching request contents.  
Mode switching completes.
- (28) Change the setting value of the communication protocol according to the communication specification.  
Mode switching complete reset
- (31) Clear the mode switching request with the clear direction.

# 21.5 How to Switch Mode from Target Device

This section shows how to switch the C24 mode from the target device.

## Mode switching procedure

The procedures for switching C24 mode from the target device.

- \*1 Inform in advance all the connected device that data communications cannot be performed due to mode switching.
- \*2 When 'CH[ ] Error occurrence' (XE, XF) turns ON, check the error contents and take the corresponding actions. (Page 519 Error Code List)
- Checking of mode switching designation contents for buffer memory mode switching area and writing of mode switching designation contents within the range that can be designated
  - Re-execution of mode switching
- \*3 When mode switching is performed from the target device, perform the read/write operation from/to the special applications area on the buffer memory shown below from the CPU module after mode switching is completed.
- 'Parameter setting error, mode switching error status' (Un\G515)
  - Initial setting areas for data communication (Un\G147 to 289/307 to 449) (Page 550 Buffer memory list)
- \*4 After confirming that mode switching was completed normally, inform all the connected devices that data communications are possible, and restart data communications.

### Point

To check C24 mode (communication protocol, transmission specifications) after mode switching, read the buffer memory (Un\G594 to 595/610 to 611). (Read the buffer memory with the MC protocol buffer memory read function when checking by the target device.) (MELSEC Communication Protocol Reference Manual)

■Program example

The following shows an example of program on the CPU module side for mode switching of the CH1 side interface from the target device.

| Category            | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Description                                          | Device  |            |                       |           |  |       |                       |   |                    |               |     |            |    |   |                         |     |     |            |     |   |                                     |     |     |            |       |

Mode switching complete reset

# 22 USING SEND/RECEIVE DATA MONITORING FUNCTION

The following describes C24 send/receive data monitoring function.

## 22.1 Send/receive Data Monitoring Function

### Overview

The send/receive data monitoring function is a function to monitor send/receive data between the C24 and a target device on communication lines.

The system startup phase can be shortened by analyzing the send/receive data on the communication lines when debugging the program.

The two methods below are available for the send/receive data monitoring method.

This chapter explains the send/receive data monitoring by the program.

#### Send/receive data monitoring by program

Monitoring is performed by writing the monitor start instruction to the send/receive data monitoring designation area of the buffer memory.

#### Send/receive data monitoring by Engineering tool

Monitoring (circuit trace) is performed by using the circuit trace function of Engineering tool (  Page 142 Circuit Trace).

# Send/receive data monitoring operation

The following describes the send/receive data monitoring operation.

## Point

- When using the send/receive data monitoring function, the total transmission speed of the two interfaces should not exceed 230400 bps.

## Start monitoring

- Write the monitor start instruction "0001H" to the send/receive data monitoring designation (Un\G8216/8472). (Set by user)
- By the monitor start instruction, the monitor data pointer/monitor data size area are cleared to '0' and "0002H" is written in the send/receive data monitoring designation area to start monitoring. (Set by C24)  
Monitor data area (Un\G9730 to 13055/13058 to 16383 (default)) is not cleared to '0'.
- When a monitor setting error occurs, "100FH" is written to the send/receive data monitoring designation area. (Set by C24)  
Review the monitor buffer start address and the monitor buffer size setting range and perform monitoring again.

## During monitoring

- Once monitoring starts, data of reception, transmission, data reception error, and signal change are stored from the start address of the monitor data area in the order of occurrence.
- When the monitored data exceeds the monitor data area size, monitoring is continued by writing new data over the oldest data.

However, monitoring may automatically stop according to the settings of the 'Monitor option specification' (Un\G8217/8473). (Page 423 Monitor option specification (Un\G8217/8473))

- Each data is stored in the monitor data area at the timing shown below.

| Data classification  |                                      | Data storage timing                                                                                                                                                                                             |
|----------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Receive data         |                                      | When data is received                                                                                                                                                                                           |
| Send data            |                                      | When data is transmitted                                                                                                                                                                                        |
| Reception error data |                                      | When a reception error is detected                                                                                                                                                                              |
| RS-232 line          | RS (RTS), ER (DTR) signals           | When the RS (RTS), ER (DTR) signals change                                                                                                                                                                      |
|                      | CS (CTS), DR (DSR), CD (DCD) signals | When signal changes are detected during the periodic processing (operation interval: 1 to 19 ms) and at the each timing described above (Monitoring is not performed to changes during the periodic processing) |

## Stop monitoring

Monitoring stops when any of the following conditions is satisfied.

- For monitor stop by user instructions  
Monitoring stops when "0000H" is written in the send/receive data monitoring designation area of the buffer memory. (Set by user)
- For monitor stop by the system when the monitor data area is full.  
The stop at buffer full specification (bit 0) of the monitor option specification area of the buffer memory is set to "ON".  
When the monitor data area is full (monitor buffer size), monitoring is automatically stopped and "1002H" is written in the send/receive data monitoring designation area. (Set by C24)
- For monitor stop by the system when the timer 0 error occurs  
The 0 timer error outbreak stop designation (bit 2) of the monitor option specification area of the buffer memory is set to "ON".  
When the timer 0 error (error code 7F40H) occurs, monitoring is automatically stopped and "1002H" is written in the send/receive data monitoring designation area. (Set by C24)  
Part of the data immediately after the occurrence of a timer 0 error may be entered in the monitor data area.

## 22.2 Send/receive Data Monitoring Function Settings

This section explains how to configure the settings for the send/receive data monitoring function.

The settings are configured with Engineering tool or by program.

### Setting with Engineering tool

The setting items for the send/receive data monitoring function are listed below.

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings"  
⇒ "Various control specification"

#### ■Parameter settings

| Parameter setting item |                               |                                                     |                                                     | Description                                                                      |
|------------------------|-------------------------------|-----------------------------------------------------|-----------------------------------------------------|----------------------------------------------------------------------------------|
| Basic settings         | Various control specification | Send/receive data monitoring function specification | Send/receive data monitoring function specification | Select "monitor start instruction" for constant monitoring.                      |
|                        |                               |                                                     | Stop at buffer full specification                   | Select "ON" to stop monitoring when the monitor data area is full.               |
|                        |                               |                                                     | 0 timer error outbreak stop designation             | Select "ON" to stop monitoring when a timer 0 error occurs.                      |
|                        |                               |                                                     | Monitor buffer start address designation            | Designate the value to change the monitor buffer address. (Default: 2600H/3300H) |
|                        |                               |                                                     | Monitor buffer size designation                     | Designate the value to change the monitor buffer size (Default: 0D00H)           |

## Buffer memory for send/receive data monitoring function

### Send/receive data monitoring designation (Un\G8216/8472)

Designate the start/stop of the send/receive data monitoring function.

For details on the send/receive data monitoring designation operation, refer to the following section.

☞ Page 420 Send/receive data monitoring operation

### Monitor option specification (Un\G8217/8473)

Designate the options of the send/receive data monitoring function.

#### ■ Stop at buffer full specification (bit 0)

- When the stop at buffer full specification is OFF  
When the monitored data exceeds the monitor data area size, monitoring is continued by writing new data over the oldest data.
- When stop at buffer full specification is ON  
When the monitor data area is full (monitor buffer size), monitoring is automatically stopped and "1002H" is written in the send/receive data monitoring designation area. (Set by C24)

#### ■ 0 timer error outbreak stop designation (bit 2)

- When the 0 timer error outbreak stop designation is OFF  
Monitoring continues even if the timer 0 error (error code 7F40H) occurs.
- When the 0 timer error outbreak stop designation is ON  
When the timer 0 error (error code 7F40H) occurs, monitoring is automatically stopped and "1002H" is written in the send/receive data monitoring designation area. (Set by C24)

### Monitor buffer start address designation (Un\G8218/8474)

Designate the start address of the storage area (monitor data area) for the monitored data within the range of the user setting area of the buffer memory.

Setting range: 0400H to 1AFDH, 2600H to 3FFDH (Default: 9728/13056 (2600H/3300H))

### Monitor buffer size designation (Un\G8219/8475)

Designate the size of the monitor data area.

Setting range: 0003H to 1A00H (Default: 0D00H)

Monitor data pointer storage area (Un\G9728/13056 (default))

■The oldest data position of the monitor data area is stored using the offset value from the start address of the monitor data area.

0 to (monitor buffer size designation (default: 0D00H) - 3): the oldest data position

■When the monitored data exceeds the monitor buffer size, the new data is written over the oldest data. (Ring buffer type)

The oldest data position of the monitor data area can be confirmed from this area.

Ex.

"Un\G9745" becomes the oldest data when "000FH" is the monitor data pointer using "Un\G9730" as the start address of the monitor data area.

Monitor data pointer storage area

Monitor data size storage area

Oldest data in the monitor data area

Monitor data quantity storage area (Un\G9729/13057(default))

The number of monitor data stored in the monitor data area is stored.

0 to (monitor buffer size designation (default: 0D00H) - 2): number of monitor data

Monitor data area (Un\G9730 to 13055/13058 to 16383(default))

The monitor data is stored in one-word units in the configuration below.  
For an example of the send/receive data monitoring, refer to the following section.

Page 426 Send/receive Data Monitoring Example

↑  
Data classification (b12 to b15)  
0: When receiving data  
1: When transmitting data  
2: When the RS(RTS)/ER(DTR) signal is changed  
3: When a reception error occurs  
4: When detecting a CD(DCD) to DR(DSR) signal change

↑  
Signal condition (b8 to b11)  
\* System area

\*1 FE : Framing error  
OVR : Overrun error  
PE : Parity error

# 22.3 Send/receive Data Monitoring Example

The following shows an example of the send/receive data monitoring for communication using the nonprocedural protocol.

## System configuration

The system configuration for the program example is as shown below.

The CH used for operation of this sample program is CH1 only.

## Program example for send/receive data monitoring

### Parameter settings

- (9) Clear the monitor data area to '0'.  
During monitor start instruction
- (24) During monitoring (002H)  
Monitor setting error (100FH)
- (46) During monitor stop (1002H)
- (52) During monitor stop instruction
- (61) Monitor stopped (0000H)

Confirming monitor data with Engineering tool

Monitor the monitor data area on the CH1 side (Un\G9730 to 13055) with the Device/Buffer Memory Batch Monitor function of Engineering tool.

For the data configuration of the monitor data area, refer to the following section.

Page 425 Monitor data area (Un\G9730 to 13055/13058 to 16383(default))

Ex.

Monitoring example when the following data is transmitted from CH1 for data communication using the nonprocedural protocol.

Send data; "ABCDEFGH" + 0D0AH (5-word)

# 23 INDEPENDENT/LINKED OPERATION OF INTERFACE

This chapter explains the independent/linked operation of C24.

## 23.1 Setting and Data Flow of Independent Operation

### Setting

For the independent operation of two interfaces on C24, configure the parameter setting as shown below.

| Setting item   |                               |                                                    | Setting content                                                                                                                   |                                     |

23

### Data flow in independent operation

Two interfaces operate independently according to the settings in the parameter settings "Basic Settings".

# 23.2 Setting and Data Flow of Interlink Operation

During the interlink operation, all data received from either one of the two interfaces is transmitted to the other interface.

Point

When two interfaces are in the interlink operation, the transmission time for one character becomes equal to the H/W gate OFF time.

## Setting

For the interlink operation of two interfaces on C24, configure the parameter setting as shown below.

| Setting item   |                               |                                                    | Setting content   |                                                                                                                                   |                                                                  |

(Same value as CH1)     |

## Data flow in interlink operation

The two interfaces operate interconnectedly using the functions configured in "Communication protocol setting" from "Basic Settings" ⇒ "CH2 side" in the module parameter (MC protocol (same format), MODBUS slave (RTU), MODBUS slave (ASCII), or nonprocedural protocol) within the transmission specifications set in the respective transmission settings.

## Precautions

### ■When setting to nonprocedural protocol

Exclusive control of the received data is necessary when data is communicated using the nonprocedural protocol since all of the connected stations receive the data.

### ■When setting to MC protocol

When data communication is performed using the MC protocol, only the C24, of which station number is specified in the message, performs the process designated by the command.

Furthermore, when data communication is performed with 2C/3C/4C frame of the MC protocol, the header information for interlink operation is added to messages directed to other stations linked by multidrop connection.

#### ● Processing performed by C24 connected to a target device

- C24 adds the header information to the command messages directed to other stations, which was received from the target device, and transmits them to the other stations through the other interface.
- C24 deletes the header information from the response messages received from the other stations, and transmits them to the target device through the other interface. (The header information is also sent during the multidrop connection using the interlink operation setting.)

#### ● Operation of the accessed station

- The accessed station processes the request contained in a command message, adds the header information to a response message, and sends it using the interface that received the command message.

### Point

The header information for the interlink operation, which is added by C24 to a message is as shown below.

- When communicating with ASCII code (Formats 1 to 4)

The following 13- or 15-character header information is added immediately before the control code (ENQ/STX/ACK/NAK) at the head of each message (13 characters for Formats 1, 3 and 4; 15 characters for Format 2).

- When communicating in binary mode (Format 5)

The following 10-byte header information is added immediately before the control code (DLE + STX) at the head of each message.

## ■When performing the interlink operation on a MODBUS slave

- For the interlink operation of a MODBUS slave, use a C24 the firmware version of which is '13' or later.
- A MODBUS master device cannot be connected to CH2 of a C24 when performing the interlink operation. Connect it to CH1.
- When a request message to a C24 is received from a MODBUS master, the C24 does not relay the request message to CH2 and sends a response message as a MODBUS slave.

- When a request message to a slave station other than a C24 is received from a MODBUS master, the C24 sends and receives the message via CH1 and CH2.

### Restriction

Do not use the above settings for the following cases because the interlink operation cannot be performed.

- When using RJ71C24-R2.
- When a target device is not connected to either of the interfaces.
- When communicating data using the predefined or bidirectional protocol.
- When communicating data using the modem function.

# Setting example for MELSOFT connection via C24

Examples of the parameter settings for MELSOFT connection via C24 are as shown below.

• Setting at station No.0

| Setting item   |                      |                                                    |                   | Setting content    |            |
|----------------|----------------------|----------------------------------------------------|-------------------|--------------------|------------|
|                |                      |                                                    |                   | CH1                | CH2        |
| Basic settings | Transmission setting | Test mode setting                                  |                   | —                  |            |
|                |                      | Communication protocol setting                     |                   | MELSOFT Connection | —          |

# 24 PARAMETER REGISTRATION TO CPU MODULE

C24 enables the parameter settings to be saved in the CPU module.

It reduces man-hours for any recovery works since the parameter resetting is not necessary at the time of replacement of C24.

The parameters controlled by the CPU module are as shown below.

| Parameters name           | Storage location of parameters                                                                                                                                                                                                                                   | File name*1                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Module parameter          | CPU built-in memory (data memory)                                                                                                                                                                                                                                | UNIT.PRM                             |
| Module extended parameter | Select from the following for each file.*2<br><ul style="list-style-type: none"> <li>CPU built-in memory (data memory)</li> <li>SD memory card installed in the CPU</li> <li>Built-in memory of Intelligent function module (in the flash ROM of C24)</li> </ul> | UEXmmmmnn.PRM*3,*4<br>UEXmmm00.PPR*3 |

\*1 It indicates a file name to store the parameters in CPU built-in memory or SD memory card.

\*2 To mount C24 on the redundant extension base unit in the redundant system, store module extended parameters to the built-in memory of intelligent function module (in the flash ROM of C24).

\*3 The value indicating the head input/output number of the module ÷ 10H (3 digits in hexadecimal) is entered in 'mmm'.

\*4 The sequential serial number of each module, 00 is entered in 'nn'.

For more details on parameters controlled by CPU modules, refer to the following manual.

 MELSEC iQ-R Programmable Controller CPU Module User's Manual

The parameters controlled by C24 parameter corresponding to CPU module are as shown below.

| Corresponding parameter controlled by CPU module | Parameter of C24          |                                                                                                           | Remarks                                                                                               |
|--------------------------------------------------|---------------------------|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|

Each file of module extended parameters held in the CPU module is given priority over the one in the flash ROM of C24.

The contents in flash ROM of C24 is replaced with the contents of module extended parameters registered in the CPU module by powering OFF → ON or switching the CPU module STOP → RUN after the module extended parameters were registered in the CPU built-in memory or SD memory card.

## Deleting module extended parameters

The following explains how to delete each file of module extended parameters.

### ■Deleting module extended parameter "UEXmmmnn.PRM"

It can be deleted by the following procedure.

1. Place the CPU module in the STOP state.
2. On the "Module extended parameter setting " screen for RJ71C24(-R2/4) of Engineering tool, restore the default setting value of module extended parameter.
3. Select [Online]⇒[Write to PLC].
4. On the "Online Data Operation" screen, select the checkbox of the corresponding Intelligent function module (C24), and perform the write operation. At this point, the content in the flash ROM of C24 is deleted.
5. On the "Online Data Operation" screen, select the [Delete] tab. When there are module extended parameters on the CPU module, "Module extended parameter: mmmm<sup>\*1</sup>" is displayed on the [Parameter] in the tree. Select the checkbox and perform the delete operation. By performing this operation, the module extended parameter on the CPU module is deleted.
6. Return the CPU module to the RUN state as necessary.

<sup>\*1</sup> The 'mmm' indicates the head input/output number of the module.

### ■Deleting module extended parameter "UEXmmm00.PPR"

It can be deleted by the following procedure.

1. Place the CPU module in the STOP state.
2. Start the Predefined protocol support function from the [Tool] menu of Engineering tool.
3. Select [Write to Module] from the [Online] menu without adding protocol.
4. On the "Module Write" screen, select "Intelligent Function Module" as the target memory, and perform the write operation. At this point, the content in the flash ROM of C24 is deleted.
5. After the step 4 above, select [Online] → [User Data] → [Delete] of Engineering tool. The "User Data Operation" screen is displayed.
6. When there are module extended parameters on the CPU module, user data "UEXmmm00.PPR<sup>\*1</sup>" is displayed. Select the checkbox and perform the delete operation. By performing this operation, the module extended parameter on the CPU module is deleted.
7. Return the CPU module to the RUN state as necessary.

<sup>\*1</sup> The value indicating the head input/output number of the module ÷ 10H (3 digits in hexadecimal) is entered in 'mmm'.

# 25 RS-422/485 INTERFACE ECHO BACK ENABLE/PROHIBIT SPECIFICATION

This chapter explains the echo back enable/prohibit specification.

This function can be used for the both interfaces on RJ71C24(-R4).

The echo back function is a function that transmitted data is also sent to RDA or RDB on the host station when data communication is performed through RS-458 (2-wire type) from RS-422/485 interface.

Whether to receive the returned data or not (discard) can be specified.

## Application

- Disabling the echo back will eliminate the processing to ignore unnecessary data, which has been programmed for nonprocedural protocol communication.
- When the same message format is used for a request (command) and a response of the target device protocol during data communication using the predefined protocol, communication with the target device can be performed by specifying "Echo back enable."

## Setting method

- Setting by engineering tool

Set "Echo back enable/prohibit specification" to "Echo back enable" or "Echo back prohibit".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

- Setting by a program

In the 'RS-422/485 interface echo back enable/prohibit specification' (Un\G290/450), store either of the following values. (Default: 0)

| Setting value         | Description                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------|
| 0: Echo back enable   | When C24 transmits data, it also receives the transmitted data with its own RDA or RDB.                             |
| 1: Echo back prohibit | When C24 transmits data, it does not receive the transmitted data with its own RDA or RDB. (The data is discarded.) |

## Precautions

The setting for the echo back enable/prohibit specification must be configured before sending data. Any setting changed during transmission does not take effect.

# 26 ERRONEOUS NOISE SIGNAL RECEPTION PREVENTION FUNCTION

This chapter explains the erroneous noise signal reception prevention function of C24.

## 26.1 Erroneous Noise Signal Reception Prevention Function

Depending on the device to be connected to C24, noise signals may be added on the line when turning ON the power or connecting cables of the device.

When noise signals are added, C24 falsely recognizes it has received improper data, and discards the data resulting in abnormal detection.

Using this function avoids erroneous noise signal reception.

This function is set in the module parameter and the 'Communication data reception enable/disable designation' (Un\G292/452).

Configure the setting to disable the reception with the parameter settings of Engineering tool, and set the buffer memory to 'Receive enable' (0) at a certain time before starting data reception after powering ON.

## 26.2 Setting for the Erroneous Noise Signal Reception Prevention Function

The setting procedure to use the erroneous noise signal reception prevention function is shown below.

### 1. Setting to disable the reception with Engineering tool

Set "Communication data reception enable/disable designation" to "Receive disable".

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

### 2. Setting to enable the reception by a program

Set the following buffer memory to 'Receive enable' (0) with a program at the timing when the serial line is settled.

| Channel | Address | Setting value      |
|---------|---------|--------------------|
| CH1     | Un\G292 | 0: Receive enable  |
| CH2     | Un\G452 | 1: Receive disable |

### Precautions

- Once the erroneous reception prevention designation area of noise signal is set to 'Receive disable' (1), normal data is not received as well.  
Set the erroneous reception prevention designation area of noise signal to 'Receive enable' (0) promptly after the serial line has been settled.
- Once it is set to 'Receive enable', it cannot be set to 'Receive disable' unless powering ON again or resetting the CPU module.

# 27 AUTOMATIC REMOVAL OF NULL CHARACTERS INCLUDED IN SEND DATA

This chapter explains the automatic removal of NULL characters in data transmission of C24.

## 27.1 Automatic Removal of NULL Characters during Data Transmission

The automatic removal of NULL characters during data transmission is a function to automatically delete NULL characters included in data transmitted to a target device from C24.

## 27.2 Setting for NULL Character Automatic Removal Function

The setting to C24 is required before data transmission in order to enable the NULL character automatic removal function for data to be transmitted using the nonprocedural protocol and the bidirectional protocol.

The settings to delete NULL characters automatically are shown below.

- The settings for automatic removal of NULL characters can be configured for each interface.
- To perform the NULL characters automatic removal function, set "NULL character automatic removal designation" to "Auto delete enabled".

Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ "Module Name" ⇒ [Module Parameter] ⇒ "Basic Settings" ⇒ "Various control specification"

# 27.3 NULL Character Removal to Send Data using Nonprocedural Protocol

This section explains automatic removal of NULL characters to data to be transmitted using the nonprocedural protocol.

## Target range of automatic removal of NULL characters

The send data range to which automatic removal of NULL characters is performed is as shown below:

- Transmitting data in arbitrary format

- Transmitting data with user frame

When data is transmitted, C24 performs the processing as follows:  
 C24 deletes NULL characters (data code: 00H) included in the data specified by the CPU module (arbitrary data portion in a transmission message) or a user frame portion, and transmits data.  
 NULL characters (00H) included in the send data in the buffer memory (send area) are deleted from the actual data to be transmitted.

To transmit data without removing NULL characters included in arbitrary user frame portion or the send area on the buffer memory when 0001H (Auto delete enabled) is set for NULL character automatic removal designation for transmitting data for data transmission with a user frame, designate the user frame number as shown below.

- Specify the number obtained by adding 4000H to the registered user frame No.

When sending data in the portions designated in 4001H to 44AFH, C000H to C01FH, the data is transmitted without conversion even when the following designations are enabled.

- Specifying an additional code by the transparent code for sending specification (Page 358 TRANSPARENT CODES AND ADDITIONAL CODES)
- Designating "Enable" in the ASCII-BIN conversion designation area (Page 379 COMMUNICATING WITH ASCII CODE (ASCII-BIN CONVERSION))

| User frame number to be transmitted | User frame designation number to transmit data without removing NULL characters (4000H added) |
|-------------------------------------|-----------------------------------------------------------------------------------------------|
| 1H to 3E7H (1 to 999)               | 4001H to 43E7H (16385 to 17383)                                                               |
| 3E8H to 4AFH (1000 to 1199)         | 43E8H to 44AFH (17384 to 17583)                                                               |
| 8000H to 801FH (-32768 to -32737)   | C000H to C01FH (-16384 to -16353)                                                             |

## 27.4 Program Example

This examples of data communication using the nonprocedural protocol are shown below.

### Program example of data communication using the nonprocedural protocol

This section shows program examples of data communication using the nonprocedural protocol when the settings/registrations are made with Engineering tool.

|                                                    |                                              |                                | Send frame No. designation (2nd) | 43F3H                              |                 |                           |
|                                                    |                                              |                                | Send frame No. designation (3rd) | C001H                              |                 |                           |
|                                                    |                                              |                                | Send frame No. designation (4th) | 8000H                              |                 | Buffer memory designation |
|                                                    |                                              |                                | Send frame No. designation (5th) | 441BH                              |                 | Arbitrary registered data |

# Example of arbitrary data transmission

C24 transmits a string data using the NULL character automatic removal function to the target device.

Ex.

Transmitting given data with OUTPUT dedicated instruction

## Program example

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Description                           | Device     |                       |            |           |       |                       |   |                   |     |            |     |   |                      |                                     |            |    |   |                        |                                     |            |    |   |                    |                     |            |     |   |                                    |     |            |     |   |                                                |     |            |    |   |                                                  |     |            |    |   |                                         |     |            |    |   |            |                                     |            |    |    |                     |     |            |      |    |                       |     |            |      |

For information on the module FB to be used, refer to the following manual.

MELSEC iQ-R Serial Communication Module Function Block Reference

## Example of transmission using user frame

C24 transmits a string data using the NULL character automatic removal function to the target device.

**Ex.**

Transmitting given data in combination with a user frame with PRR dedicated instruction

## Program example

For information on the module FB to be used, refer to the following manual.

MELSEC iQ-R Serial Communication Module Function Block Reference

# 27.5 NULL Characters Removal for Send Data using Bidirectional Protocol

This section explains automatic removal of NULL characters to data to be transmitted using the bidirectional protocol.

## Target range of automatic removal of NULL characters

The send data range to which automatic removal of NULL characters is performed is as shown below. However, the automatic removal of NULL characters is not performed when a response message is transmitted.

\*NULL characters automatic deletion is disabled when transmitting a response message.

When data is transmitted, C24 performs the processing as follows:

- Range of automatic removal of NULL characters  
C24 performs the automatic removal of NULL characters to an arbitrary data portion of a message (data length is not included).
- Automatic removal of NULL characters in data portion  
C24 deletes NULL characters included in send data, and then transmits data.
- Handling of sum check code  
The results of adding the data portion after automatic removal of NULL characters as binary code data are added to the transmission message as sum check code.

\*1 Calculation of sum check code is shown below:

$$06H + 00H + 31H + 32H + 33H + 41H + 42H + 43H = 0162H$$

(H) (L)

## Precautions

When the automatic removal of NULL characters is performed to data transmitted using the bidirectional protocol, always specify the "Word/byte units designation" to "Byte units".

Ex.

Example of data transmission after automatic removal of NULL characters using the bidirectional protocol

## 27.6 Program Example

The examples of data communication using the bidirectional protocol are shown below.

### Program example of data communication using the bidirectional protocol

This section shows program examples data communication using the bidirectional protocol when the settings/registrations are made with Engineering tool.

#### parameter setting

For details for each setting item, refer to the parameters. (  Page 454 PARAMETER SETTING)

## Example of data transmission

C24 transmits a string data using the NULL character automatic removal function to the target device.

**Ex.**

Transmitting given data with BIDOUT dedicated instruction

## Program example

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                           | Device     |                       |            |           |       |                       |   |                   |     |            |     |   |                      |                                     |            |    |   |                        |                                     |            |    |   |                    |                     |            |     |   |                                    |     |            |     |   |                                                |     |            |    |   |                                                  |     |            |    |   |                                         |     |            |    |   |            |                                     |            |      |    |                     |     |            |      |    |                       |     |            |      |

For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

## PART 3

# PARAMETER SETTINGS AND TROUBLESHOOTING

## PART 3

This part explains parameters and troubleshooting of C24.

28 PARAMETER SETTING

---

29 TROUBLESHOOTING

---

# 28 PARAMETER SETTING

---

This section explains parameter settings necessary for data communication between C24 and a target device.

## 28.1 Parameter Setting Procedure

---

This section explains the parameter setting procedure to use RJ71C24.

1. Add C24 to Engineering tool.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

2. Module parameters and module extended parameters are included in parameters. There are four types of module parameters: basic settings, application settings, interrupt settings, and refresh setting, and three types of module extended parameters: user frame contents, modem initialization data, and modem connection data, which are selected from the tree in the screen below.

 Navigation window ⇒ [Parameter] ⇒ [Module Information] ⇒ RJ71C24 ⇒ [Module Parameter]/[Module Extended Parameter]

3. Write the settings to the CPU module with Engineering tool after the parameter setting is completed.

 [Online] ⇒ [Write to PLC]

4. The settings are reflected by resetting the CPU module or turning the power OFF → ON.

# 28.2 Module Parameters

Set the module parameters. The module parameter includes the following four types: basic settings, application settings, interrupt settings, and refresh setting, which is selected from the tree in the screen below.

Navigation window ⇒ [Parameters] ⇒ [Module Information] ⇒ Module name ⇒ [Module Parameter]

## Basic settings

Configure the settings to operate the basic functions of C24.

### Window

## Various control specification

Specify the various controls.

\*1 It can be set only on the CH1 side. When the test mode is selected, the communication protocol setting on the CH1 side and the setting on the CH2 side cannot be configured (will be invalid).

\*2 It will be enabled only when "MELSOFT Connection" is selected for the communication protocol setting.

\*3 It can be set on the CH2 side only. (Since the linked operation is not available for RJ71C24-R2, it is fixed to "Independent".) When it is set to "Interlink", the communication protocol setting for the CH2 side cannot be configured.

\*4 Set '8' for data communication using MC protocol (format 5), bidirectional protocol, or MODBUS slave (RTU). For data communication using simple CPU communication, it differs depending on the device type of a communication destination.

\*5 It can be set when "MODBUS Slave (RTU)" or "MODBUS Slave (ASCII)" is selected for the communication protocol setting.

\*6 n: 1 to 10

\*7 It will be enabled when "Simple PLC Communication" is selected for the communication protocol setting.

# Application settings

Configure the settings such as the user frame specification.

|                                | Connection re-try count designation                                 | Sets a number of retries for the connection request.                                                                                                                                                | 1 to 5<br>(Default: 5)                                                                                                                                             |
|                                | Connection retry interval designation                               | Sets an interval of the retry processing for the connection request.<br>(Unit: s)                                                                                                                   | 90 to 300<br>(Default: 180)                                                                                                                                        |
|                                | Initialization/connection timeout designation                       | Sets the wait time below. <ul style="list-style-type: none"> <li>• Wait time until the modem/TA initialization is complete.</li> <li>• Wait time per one connection request</li> </ul> (Unit: s)    | 1 to 60<br>(Default: 60)                                                                                                                                           |
|                                | Number of initialization retries designation                        | Sets a number of initialization retries to the modem.                                                                                                                                               | 1 to 5<br>(Default: 3)                                                                                                                                             |
|                                | Data No. for initialization designation                             | Sets the data number to be transmitted by the initialization request to the modem.                                                                                                                  | 0000H,<br>07D0H to 07DDH (2000 to 2013),<br>09C4H to 09E1H (2500 to 2529)<br>8001H to 801FH (32769 to 32799)<br>(Default: 0000H: No designation)                   |
|                                | Data No. for connection designation                                 | Sets the data number for connection to be used for the processing to connect to a target device for data transmission.                                                                              | 0000H,<br>0BB8H to 0BD5H (3000 to 3029)<br>8001H to 801FH (32769 to 32799)<br>(Default: 0000H: No designation)                                                     |
|                                | No-communication interval time designation                          | Sets the wait time before the line is closed when data communications with a target device is ceased after the line has been connected.<br>0: Infinite wait<br>1 to 120 (unit: minute)              | 0: Infinite wait<br>1 to 120<br>(0: Infinite wait)                                                                                                                 |
|                                | RS/CS control enable/disable designation                            | Sets whether or not the control to notify the reception capability of the host station to the target side with RS/CS signal is performed during data communication between C24 and a modem/TA.      | <ul style="list-style-type: none"> <li>• Control disabled</li> <li>• Control enabled</li> </ul> (Default: Control enabled)                                         |
| Modem function specification 2 | Auto modem initialization designation                               | Sets whether or not the modem is automatically initialized.                                                                                                                                         | <ul style="list-style-type: none"> <li>• Do not automatically initialize</li> <li>• Automatically initialize</li> </ul> (Default: Do not automatically initialize) |
|                                | Modem initialization DR (DSR) signal enable/disable designation     | Sets how to treat DR signal when initializing a modem.                                                                                                                                              | <ul style="list-style-type: none"> <li>• DR signal enabled</li> <li>• DR signal disabled</li> </ul> (Default: DR signal disabled)                                  |
| Modem function specification 3 | Line disconnection wait time specification (PLC CPU monitor)        | Sets the time until data transmission from a modem on the host station side to the target device side is completed for data communication with the programmable controller CPU monitoring function. | 0000H to FFFFH<br>(Default: 0000H)                                                                                                                                 |
| Remote password function       | Remote password mismatch notification count designation             | Sets the number of times to notify the CPU module that a remote password mismatch occurred during the unlock processing by a target device after the modem line has been connected.                 | 0000H to FFFFH<br>(Default: 0000H: No designation)                                                                                                                 |
|                                | Remote password mismatch notification accumulated count designation | Set the accumulated number of times to notify the CPU module that a remote password mismatch occurred during the unlock processing by a target device after C24 has started up.                     | 0000H to FFFFH<br>(Default: 0000H: No designation)                                                                                                                 |

## Programmable controller CPU monitoring function setting

Set the system setting value to use the programmable controller CPU monitoring function.

| Item                                                                          |                                            | Description                                                                                        | Setting range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# MODBUS slave settings

Configure the settings for communication using the MODBUS slave function.  
This can be set when "MODBUS Slave (RTU)" or "MODBUS Slave (ASCII)" is selected for the communication protocol setting.

## MODBUS device assignment parameters

MODBUS device assignment parameters are used for associating MODBUS devices with device memories of a CPU module. By using them, direct access from a MODBUS master device to device memories of a CPU module is available.

The range of devices to be assigned must be set so that it does not exceed the range of devices that can be used for a CPU module.

The following items can be set for each allocation 1 to 16.

| Item                       | Description                                                                                                                                                                                                                                                                                                                              | Setting range                                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device code                | Set a device of a CPU module to be assigned to a MODBUS device.                                                                                                                                                                                                                                                                          | <ul style="list-style-type: none"> <li>For using the buffer memory: HC000 to HCFFF</li> <li>Devices other than the buffer memory (H): Follow the device settings of the CPU parameter. (Default:  Page 470 Default assignment parameters)</li> </ul> |
| Start device number        | Specify the start device number in hexadecimal regardless of the device type. Set 'H' for the device code when using the buffer memory. Set an address of 'User setting area for MODBUS' (Un\G49152 to Un\G53247) in hexadecimal (C000H to CFFFH) for the start device number.                                                           |                                                                                                                                                                                                                                                      |
| Start MODBUS device number | Set the start number of a MODBUS device to which a device of a CPU module is assigned. A setting value of the start MODBUS device number can be calculated with the following formula:<br><ul style="list-style-type: none"> <li>Start MODBUS device number = Last five digits of the setting target MODBUS device number - 1</li> </ul> |                                                                                                                                                                                                                                                      |
| Allocation points          | Set the number of device points of a CPU module assigned to a MODBUS device.                                                                                                                                                                                                                                                             | 0 to 65535<br>(Default:  Page 470 Default assignment parameters)                                                                                                                                                                                     |

The following shows the schematic diagram of the MODBUS device assignment parameter setting.

## Available devices

The following table lists the devices of a CPU module that can be set for MODBUS devices.

| Device                |                             |             |             | MODBUS device (○: Assignable, ×: Not assignable) |       |                |                  |                        |
|-----------------------|-----------------------------|-------------|-------------|--------------------------------------------------|-------|----------------|------------------|------------------------|
| Device name           | Symbol                      | Device code | Type        | Coil                                             | Input | Input register | Holding register | Extended file register |
| Special relay         | SM                          | 0002H       | Bit         | ○                                                | ○     | ○*1            | ○*1              | ×                      |

\*1 When setting a bit type device for an input register and output register, set the number of assigned points to a multiple of 16.

\*2 Two points of MODBUS devices are used.

\*3 Fixed to the file register (ZR).

\*4 The long timer (current value) and long retentive timer (current value) use four points of MODBUS devices. (Page 469 Reading of the long timer and long retentive timer)

\*5 The step relay is read-only. An attempt of writing will cause an error.

### ■Reading of the long timer and long retentive timer

When reading the long timer and long retentive timer, note that the following devices cannot be set:

- Long timer (contact)
- Long timer (coil)
- Long retentive timer (contact)
- Long retentive timer (coil)

When, however, the current value of the long timer or long retentive timer is set in units of four words, the contact and coil will be read simultaneously.

| Response data | Description                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1st word      | The current value is stored.                                                                                                                                                      |

| 4th word      | <ul style="list-style-type: none"> <li>• b0: The value of a coil is stored.</li> <li>• b1: The value of a contact is stored.</li> <li>• b2 to b15: Used by the system.</li> </ul> |
|               | Used by the system.                                                                                                                                                               |

As shown above, the long timer and long retentive timer use the data configuration of four words per device. Consequently, specify the number of device points in units of four points.

### ■Writing of the long timer and long retentive timer

Note that the long timer and long retentive timer cannot be set.

### ■MODBUS extended file register assignment

The assignment of the MODBUS extended file register to the CPU module is fixed to the file register (ZR).

The following shows the assignment to the file register of the CPU module. (The number of points for the file register shows the maximum size that can be set in the CPU module (when the R120CPU + NZ2MC-16MBS are mounted)).

### ■Size of a MODBUS extended file register

The size of a MODBUS extended file register depends on that of the file register (ZR) set in a CPU module.

For details, refer to the following manual.

📖 MELSEC iQ-R Programmable Controller CPU Module User's Manual

## Default assignment parameters

The MODBUS device assignment parameters include default assignment parameters as initial values.

The following diagram shows the MODBUS device assignment using the default assignment parameters.

### Point

- In the MODBUS device assignment parameters, the 'Start MODBUS device number' is the 'Last five digits of the setting target MODBUS device number - 1.'
- If a CC-Link IE Field Network remote head module is set as an access target, default values set for the MODBUS device assignment parameters cannot be used.

# Interrupt settings

Configure the settings to receive data with an interrupt program.

## Refresh setting

---

With this refresh settings, the read and write processing by a program is not necessary.

Set a device/module label of the CPU module which transfers data alternately with the buffer memory on C24.

The device/module label to be transmitted is selected from the following from "Target".

- Module label
- Refresh Data Register (RD)
- Device

### Module label

The contents are transferred alternatively between the module label corresponding to each buffer memory and the buffer memory. Set "Valid" for the item to be transferred using module labels and "Invalid" for the item not to be transferred. By enabling "Send data\_send area", the other transfer destinations will be set to "Valid".

### Refresh data register (RD)

The contents are transferred alternatively between the refresh data register (RD) of a CPU module and the buffer memory. By setting the refresh data register (RD) to be transferred in "Top Device Name", the other transfer destinations will be automatically set.

### Device

The contents are transferred alternatively between the designated device of a CPU module and the buffer memory. The devices that can be designated are X, Y, M, L, B, T, C, ST, D, W, R, ZR, and RD. When bit devices, X, Y, M, L, or B are used a number that can be divided by 16 points (for example, X10, Y120, M16, etc.) should be set. The buffer memory data is stored in the equivalent of 16 points from the designated device number.

(For example, when X10 is set, data is stored from X10 to X1F.)

## Refresh processing time

A refresh processing time ( $\mu\text{s}$ ) is a constituent of the scan time of CPU module. For details on the scan time, refer to the following manual.

 MELSEC iQ-R Programmable Controller CPU Module User's Manual

The refresh processing time ( $\mu\text{s}$ ), which is taken for the refresh, is given by:

- Refresh processing time ( $\mu\text{s}$ ) = Refresh read time (time for transferring refresh data to the CPU module) + Refresh write time (time for transferring refresh data to the Intelligent function module)

The refresh read time and refresh write time vary depending on the settings of "Target".

### ■When "Target" is "Module Label" or "Refresh Data Register (RD)"

The following table shows the refresh read time and refresh write time with an R□CPU used.

| Classification     | Refresh processing time |
|--------------------|-------------------------|
| Refresh read time  | 80.80 $\mu\text{s}$     |
| Refresh write time | 20.48 $\mu\text{s}$     |

### ■When "Target" is "Device"

Calculate the refresh read time and refresh write time according to the number of items and the number of their transfer data (in units of word) that are set to be refreshed. For the calculation method, refer to the following manual.

 MELSEC iQ-R Programmable Controller CPU Module User's Manual

In addition, substitute the following values in the calculation formula to calculate the refresh processing time.

| Item                                                 | Description                                   |
|------------------------------------------------------|-----------------------------------------------|
| Number of refresh settings                           | Number of items that are set to be refreshed  |
| Refresh time (A) of each of the 1st to nth set items | 0.05 $\mu\text{s}$ per one word <sup>*1</sup> |
| Refresh time (B) of each of the 1st to nth set items | 0.01 $\mu\text{s}$ per one word <sup>*1</sup> |

<sup>\*1</sup> This value is the time with an R□CPU used.

**Ex.**

When all the 48 items (1068 words in total) are set in the refresh read settings

$$48 \times 0.98 + 0.05 \times 1068 + 11.6 = 112.04 \mu\text{s}$$

The refresh read time, therefore, is 112.04  $\mu\text{s}$ .

**Ex.**

When all the 2 items (1022 words in total) are set in the refresh write settings

$$2 \times 0.58 + 0.01 \times 1022 + 9.10 = 20.48 \mu\text{s}$$

The refresh write time, therefore, is 20.48  $\mu\text{s}$ .

## 28.3 Module Extended Parameter

Set a module extended parameter. The module extended parameter includes user frame contents, modem initialization data, modem connection data, and simple CPU communication setting which are selected from the tree on the following screen.

Navigation window ⇒ [Parameters] ⇒ [Module Information] ⇒ Module Name ⇒ [Module Extended Parameter]

### User frame contents

Register the user frame which is used for the on-demand function using the MC protocol and the data transmit/receive function using nonprocedural protocol.

In the user frame contents, the setting value for each frame of the registration frame No. 1000 to 1199 is set.

#### Window

#### Setting data

| Item       | Description                              | Setting range                                         |
|------------|------------------------------------------|-------------------------------------------------------|
| User frame | Sets the setting value for a user frame. | 80 (maximum number of characters that can be entered) |

# Modem initialization data

In the modem initialization data, the data for initialization of the data number from 2500 to 2529 is set.

| CPU Response Monitoring Timer           | Set the time for monitoring the response from the CPU module.<br>If there is no response from the CPU module within a set time, the response waiting state is released. | Unit: s<br>• 1 to 16383<br>Unit: ms<br>• 100 to 16383000 |
| Unit                                    | Select the unit of a CPU response monitoring timer.                                                                                                                     | • s<br>• ms                                              |
| Latency Time                            | Set a time to start communication after the CPU module is started.<br>(Unit: s)                                                                                         | Page 479 Simple CPU communication setting                |
| Simple PLC Communication Setting No.□*1 | Configure the settings to perform simple CPU communication.<br>Set a communication pattern, communication destination, and devices to be sent and received.             |                                                          |

\*1 □: 1 to 512

### Point

"Simple PLC Communication Setting" can be set up to 512 with an engineering tool; however, when setting as a communication destination, up to 1 (RS-232) and 32 (RS-422/485) can be set for each channel.

### Restriction

In GX Works3, if a project satisfies all the following conditions, the values in the simple CPU communication setting may become incorrect when opening the setting in version 1.072A or earlier.

- A serial communication module was placed in a project in version 1.072A or earlier.
- The above project was opened in version 1.075D or later, and the simple CPU communication setting was configured.

In this case, upgrade the version to 1.075D or later, then open the simple CPU communication setting.

# Simple CPU communication setting

Set the following items to perform simple CPU communication.

A setting screen appears by double-clicking any one of "Simple PLC Communication Setting No.1" to "Simple PLC Communication Setting No.512" in the "Simple PLC Communication Setting" screen.

| Communication Time-out Period (ms) |        | Set the time to start a retry after an error response is received from a communication destination, to regard the state as an error, or to wait for a response from a communication destination.<br>Set it as follows: (Communication time-out period) $\geq$ (Execution interval)<br>For details on the communication time-out period, refer to the following section.<br><ul style="list-style-type: none"> <li>When selecting "Fixed Interval" for the communication setting:  Page 124 Operation when an error occurs</li> <li>When selecting "On Request" for the communication setting:  Page 129 Operation when an error occurs</li> </ul> (Unit: ms) | 10 to 65535<br>(Default: 5000)                                                                                                                                    |
| Communication Retry Count          |        | Set the number of times to repeat a waiting operation in the communication time-out period if there is an error response or no response from a communication destination.<br>For details on the communication retry count, refer to the following section.<br><ul style="list-style-type: none"> <li>When selecting "Fixed Interval" for the communication setting:  Page 124 Operation when an error occurs</li> <li>When selecting "On Request" for the communication setting:  Page 129 Operation when an error occurs</li> </ul>                                                                                                                         | 0 to 255<br>(Default: 3)                                                                                                                                          |
| Monitoring Time At Error (s)       |        | Set the communication time after a communication error occurs.<br>For details on the monitoring time at error, refer to the following section.<br> Page 124 Operation in an abnormal state<br>(Unit: s)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 1 to 300<br>(Default: 30)                                                                                                                                         |
| Comment                            |        | Enter a comment for each setting number.<br>The comment must be set in the same language as the display language of GX Works3.<br>If these languages differ, the verification result may be mismatched or the comment may not be displayed properly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Up to 32 characters<br>(Default: Blank)                                                                                                                           |

### Point

- The actual execution interval is affected by a communication destination and communication speed; therefore, it may become longer than the set execution interval.
- When setting "Latency Time," a data communication is performed after a latency time elapses.

## ■Latency time

A timing to start communication can be delayed by setting a latency time for the following cases:

- To avoid an error due to the concentrated communication and overlapped timing to start communication
- To start communication after the communication destination become available to communicate

During a latency time, '1' (preparing) is stored in 'Communication status' for each setting number.

### Point

During a latency time, a communication at an execution interval set to "Fixed Interval" is ignored.

## Communication destination setting

The following table lists the communication destination settings specified for simple CPU communication.

### ■ Host station channel number, station number

| Item                       | Description                                                                                                                                                                                                                                                                                                                                  | Setting range                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Station Channel No.*1 | Set the channel number of the host station.                                                                                                                                                                                                                                                                                                  | <ul style="list-style-type: none"> <li>• CH1 (RS-232)</li> <li>• CH2 (RS-232)</li> <li>• CH1 (RS-422/485)</li> <li>• CH2 (RS-422/485)</li> </ul> |
| Station No.                | Set the station number when a communication destination is a MODBUS-compatible device. <ul style="list-style-type: none"> <li>• 0: Broadcast (A request message is sent to all slave stations.)</li> <li>• 1 to 247: Station number of a slave to be communicated</li> </ul> Cannot be set when a communication destination is a CPU module. | 0 to 247                                                                                                                                         |

\*1 Displayed in the name of a communication destination.

28

#### Point

When setting "Station No." to '0' (broadcast), configure the settings as follows:

- "Communication Pattern": "Write"
- "Bit Device" and "Word Device": Cannot be set together. Select either one for each setting.
- "Communication Time-out Period": Set the value as the broadcast delay.

Broadcast is sent to all slave devices; therefore, consider each processing time of all slave devices and set the sufficient time for communication time-out period (broadcast delay).

If there is a slave device the communication time-out period of which is set insufficiently, an error may occur for another request to the slave device.

### ■ Device type

Configure the setting of a communication destination for devices (transfer source and transfer destination).

| Item        | Description                                             | Setting range                                                                                                                                                    |
|-------------|---------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device Type | Specify the device type of a communication destination. | <ul style="list-style-type: none"> <li>• MELSEC-A/AnS (CPU COM)</li> <li>• MODBUS (RTU)-compatible device</li> <li>• MODBUS (ASCII)-compatible device</li> </ul> |
| Option 1    | Cannot be set.                                          | —                                                                                                                                                                |
| Option 2    | Cannot be set.                                          | —                                                                                                                                                                |

The following shows compatible devices for each device type.

| Device type                      | Communication destination                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# 29 TROUBLESHOOTING

This chapter explains the errors which may occur when using C24 and the corrective actions.

## 29.1 Checking Module Status

The following functions can be used in the "Module Diagnostics" screen of C24.

| Function                | Description                                                                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error Information       | Contents of error currently occurs are displayed.<br>Errors detected on C24 and history of operation performed to the module can be checked by clicking the [Event History] button. |
| Module Information List | Various status information of C24 is displayed.                                                                                                                                     |

### Error information

Check the content of error currently occurs and the corrective actions.

| Item                 | Description                                                |
|----------------------|------------------------------------------------------------|
| Detailed Information | Up to three detail information of each error is displayed. |
| Cause                | Detail reasons for error is displayed.                     |
| Corrective Action    | Corrective actions for an error is displayed.              |

# Module information list

Check each status information of C24 by switching to the [Module Information List] tab.

## Checking error status

The transmission status and the communication error status for C24 can be checked with Engineering tool. (Contents of the 'CH□ side LED lighting status and communication error status' (Un\G513/514) are displayed.)  
When a communication error occurs, refer to the following section and take corrective action.

Page 500 Troubleshooting by Symptom

Point

Each communications error status of SIO, PRO., P/S, and C/N turns ON when an error occurs.  
To turn them OFF by clearing the communication error status, turn 'Error initialization request' (YE) ON.

### ■SD WAIT

SD WAIT indicates "Transmission wait status".

| Value      | Status                        | Description                                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Waiting for data transmission | C24 got into a state in which data cannot be sent to a target device (waiting for data transmission) by the transmission control of C24. <ul style="list-style-type: none"> <li>The transmission cannot be started.</li> <li>A transmission terminate request (receiving DC3/DR(DSR) signal OFF) is received from the target device during data transmission.</li> </ul> |
| 0000 (OFF) | Data transmission available   | The transmission became available, and the data transmission is started/resumed.                                                                                                                                                                                                                                                                                         |

### ■SIO

SIO indicates "SIO error status".

| Value      | Status                            | Description                                                                                                                                                                                                                                 |
|------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Overrun or framing error occurred | Overrun or framing error occurred. Keeps the ON-status even after the communication returns to normal. Initialize the error information as necessary. <a href="#">Page 519 Error Code List</a>                                              |
|            | OS area is full.                  | No free space is available in the OS area, and the received data was discarded. Keeps the ON-status even after the communication returns to normal. Initialize the error information as necessary. <a href="#">Page 519 Error Code List</a> |
| 0000 (OFF) | Normal                            | —                                                                                                                                                                                                                                           |

### ■PRO.

PRO. indicates "Character error status".

| Value      | Status         | Description                                                                                                                                                                           |
|------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Error occurred | Character error occurred. Keeps the ON-status even after the communication returns to normal. Initialize the error information as necessary. <a href="#">Page 519 Error Code List</a> |
| 0000 (OFF) | Normal         | —                                                                                                                                                                                     |

### ■P/S

P/S indicates "Status of parity error or sum check error".

| Value      | Status         | Description                                                                                                                                                                                           |
|------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Error occurred | Parity error or sum check error occurred. Keeps the ON-status even after the communication returns to normal. Initialize the error information as necessary. <a href="#">Page 519 Error Code List</a> |
| 0000 (OFF) | Normal         | —                                                                                                                                                                                                     |

## ■C/N

C/N indicates 'Access status with the CPU module'.

| Value      | Status         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Error occurred | <ul style="list-style-type: none"><li>The target device issued a data write request to the CPU module when online change is set to 'Disable' in the parameter settings with Engineering tool.</li><li>For functions that cannot be used when online change is set to 'Disable', refer to the explanation section in each command list in the following manual.<br/>( MELSEC Communication Protocol Reference Manual)</li><li>An error occurred during the access between C24 and the CPU module.</li></ul> Keeps the ON-status even after the communication returns to normal. Initialize the error information as necessary.<br> Page 519 Error Code List |
| 0000 (OFF) | Normal         | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## ■NAK

NAK indicates "Abnormal completion status".

| Value      | Status                                                      | Description                                                                                                                                                                                                           |
|------------|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Abnormal completion transmission                            | C24 that could not receive data normally sent a response message (NAK message) to the target device to notice the abnormal completion.                                                                                |
| 0000 (OFF) | Normal completion transmission or before data communication | <ul style="list-style-type: none"><li>C24 that could receive data normally sent a response message (ACK message) to the target device to notice the normal completion.</li><li>Before data is communicated.</li></ul> |

## ■ACK.

ACK. indicates "Normal completion status".

| Value      | Status                                                        | Description                                                                                                                                                                                                                 |
|------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0001 (ON)  | Normal completion transmission                                | C24 that could receive data normally sent a response message (ACK message) to the target device to notice the normal completion.                                                                                            |
| 0000 (OFF) | Abnormal completion transmission or before data communication | <ul style="list-style-type: none"><li>C24 that could not receive data normally sent a response message (NAK message) to the target device to notice the abnormal completion.</li><li>Before data is communicated.</li></ul> |

## ■NEU.

NEU. indicates "Command message to be received/command message in processing".

NEU. is valid only when MC protocol (format 1 to 5), MODBUS slave (RTU), or MODBUS slave (ASCII) is set in the communication protocol setting.

This is in the OFF-status when an item other than MC protocol (format 1 to 5), MODBUS slave (RTU), or MODBUS slave (ASCII) is set.

| Value      | Status            | Description                                 |
|------------|-------------------|---------------------------------------------|
| 0001 (ON)  | Neutral           | Waiting for command message to be received. |
| 0000 (OFF) | Command reception | Command message is in process.              |

# Checking transmission setting

Details of transmission settings can be monitored.

# Intelligent function module monitor

Check the status information of C24 on the "Intelligent Function Module Monitor" screen.  
For details of the "Intelligent Function Module Monitor" screen, refer to the following manual.  
 GX Works3 Operating Manual

## RS-232 control signal status reading method

The following shows how to read the control signal status stored in the buffer memory during communication using RS-232 interface.  
This is a read operation to check the signal ON/OFF status of the RS-232 interface when a transmission problem occurs.

### ■RS-232 control signal status (Un\G596/612)

The RS-232 control signal status is stored as follows:

- Remarks
- For details on signals for RS-232, refer to the following section.  
 MELSEC iQ-R Serial Communication Module User's Manual(Startup)  
Signals output from the C24 side (RS(RTS) and ER(DTR)) are controlled by the system (operating system) of C24. They cannot be directly controlled by the program.  
A lag of 100 ms at maximum occurs in the signal status stored in the buffer memory above.

**Data communication status (transmission sequence status) reading method**

The following shows how to read the current data communication status using the MC protocol stored in the buffer memory. This read processing is for checking the data communication status using the MC protocol when a transmission problem occurs.

**■Transmission sequence status (Un\G597/613)**

The status of data communication using the MC protocol is stored as a numeric value as shown below.

|                       |         |        |    |    |                               |
|-----------------------|---------|--------|----|----|-------------------------------|
|                       |         | b15    | to | b6 |                               |
| Buffer memory address | Un\G597 | 0 to 9 |    |    | (Information on the CH1 side) |
|                       | Un\G613 | 0 to 9 |    |    | (Information on the CH2 side) |

The following shows the correspondence between the numerical values in the transmission sequence status storage area and the data communication status.

• Remarks

When the target interface is not set to use the MC protocol, '0' is stored in the 'Transmission sequence status' (Un\G597/613).

## Current operation status reading method

The following shows how to read the current operation status of C24.

For details on the contents of each parameter setting, refer to the following manual.

Page 454 PARAMETER SETTING

### ■Operation mode status storage area

The current operation status of C24 is stored in the following buffer memory areas.

- Station number (instruction setting) (Un\G591)

- Communication protocol status (Un\G594/610)

- Transmission setting status (Un\G595/611)

For the correspondence table for the communication speed setting, see the table below.

1: ON, 0: OFF

| Communication speed setting | b11 | b10 | b9 | b8 |
|-----------------------------|-----|-----|----|----|
| 1200 bps                    | 0   | 0   | 1  | 0  |
| 2400 bps                    | 0   | 0   | 1  | 1  |
| 4800 bps                    | 0   | 1   | 0  | 0  |
| 9600 bps                    | 0   | 1   | 0  | 1  |
| 14400 bps                   | 0   | 1   | 1  | 0  |
| 19200 bps                   | 0   | 1   | 1  | 1  |
| 28800 bps                   | 1   | 0   | 0  | 0  |
| 38400 bps                   | 1   | 0   | 0  | 1  |
| 57600 bps                   | 1   | 0   | 1  | 0  |
| 115200 bps                  | 1   | 0   | 1  | 1  |
| 230400 bps                  | 1   | 1   | 0  | 0  |

- MODBUS station number confirmation (Un\G31750)

## Check method for the communication status of the MODBUS slave function

The following explains the check method for the communication status of the MODBUS slave function.

When using the MODBUS slave function, the number of error occurrences during communication is stored in the buffer memory.

The communication status can be checked by reading the counter of the number of error occurrences by either of the following method:

- Checking in the "Intelligent Function Module Monitor" screen
- Accessing from a master device with any of the MODBUS standard functions (FC: 08H) (  Page 116 Function List)

| Counter                                     |                                                                                                                                                                                                                                                                                                                                                   | Buffer memory    |                  | MODBUS standard function                               |           |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|------------------|--------------------------------------------------------|-----------|
| Type                                        | Description                                                                                                                                                                                                                                                                                                                                       | CH1              | CH2              | Function name                                          | Code      |

|                                             |                                                                                                                                                                                                                                                                                                                                                   |                  |                  | Return IOP overrun error count                         | 08H (13H) |
| Message discard count                       | Counts the number of times that request messages were discarded when a request message was being processed by a slave or a request message to another station was received.                                                                                                                                                                       | 32515<br>(7F03H) | 32579<br>(7F43H) | —                                                      |           |
| Data discard count                          | Counts the number of times that improper data (such as a request message the data structure of which does not comply with the frame specifications) was discarded.                                                                                                                                                                                | 32516<br>(7F04H) | 32580<br>(7F44H) |                                                        |           |
| Failed transmission count                   | Counts the number of times that transmission of response messages failed.                                                                                                                                                                                                                                                                         | 32517<br>(7F05H) | 32581<br>(7F45H) |                                                        |           |

\*1 The bus message count is in an exclusive relationship with the bus communication error count.

## ■Count range

0000H to FFFFH are counted.

The count is stopped if it has reached FFFFH. To continue, clear the counter.

## ■Methods for clearing a counter

A counter can be cleared by any of the following methods:

- Turning the power OFF and ON
- Resetting a CPU module
- Clearing the buffer memory to '0' by using a sequence program
- Receiving any of the following MODBUS standard functions:

| MODBUS standard function               |           | Counter that can be cleared                                                                                                                                                                                                                          |
|----------------------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Clear overrun counter and flag         | 08H (14H) | Character overrun count                                                                                                                                                                                                                              |

## Error information clear

This section explains the factors causing the ERR LED to be turned ON and the error code initialization (clear) for C24.

### Factors causing ERR LED to turn ON

When any of the following errors occurs, its error code is stored in the buffer memory corresponding to the interface (CH) where the error occurred, and the ERR LED turns ON.

The meanings of abbreviations in the table are as follows:

- MC: MC protocol
- Non: Nonprocedural protocol
- Bi: Bidirectional protocol
- Pd: Predefined protocol
- MD: MODBUS (slave function)
- S: Simple CPU communication

| Error factor                       | Error code storage buffer memory |           |                                                                  | Applicable protocol |     |    |    |    |   |
|------------------------------------|----------------------------------|-----------|------------------------------------------------------------------|---------------------|-----|----|----|----|---|
|                                    | Address                          |           | Name                                                             | MC                  | Non | Bi | Pd | MD | S |
|                                    | CH1                              | CH2       |                                                                  |                     |     |    |    |    |   |

## Factors causing ERR LED to flash

When any parameter error was detected, the ERR LED flashes, and the buffer memory address which is set out of the range of the parameter setting value is stored in the error address storage area (Un\G20224 to 20231).

## Turning OFF the ERR LED and initializing the error codes

Turn 'Error initialization request' (YE) ON to turn the ERR LED OFF and initialize the error code.

- The buffer memory, which is a factor in turning the LED ON, is initialized.
- The protocol execution logs are not initialized.

## Individual station test

When a problem occurs during data communication with a target device, perform an individual station test to check whether or not there is any problem in the operation of C24.

The individual station test consists of the following two tests:

- Hardware test
- Self-loopback test

### Precautions

- To prevent any problems from occurring, set the CPU module in the STOP state during the individual station test.
- When either one of the interfaces needs to be tested, disregard the test result for the other interface.
- Cable removal and reconnection before and after the self-loopback test should be performed with the power to the station with C24 turned OFF.
- Before starting data communication with the target device after the individual station test, configure the respective setting and connect the cable by checking the specifications for the functions to be used.
- Do not execute the firmware update, when an individual station test is being performed.
- If an error occurs even though the settings have been configured correctly for C24 through an individual station test, please consult your local Mitsubishi representative, explaining a detailed description of the problem.

## Hardware test

The hardware test is a test to check the memory of C24.

Perform the hardware test according to the procedure described below.

### Operating procedure

#### 1. Test mode setting ( Page 454 PARAMETER SETTING)

- Set the test mode setting to "Hardware test".
- Configure all of the transmission settings and communication speed setting for the two interfaces according to the transmission specifications for data communication with a target device.
- Set the CPU module to the STOP state, and write the parameters.

#### 2. Performing hardware test

By restarting or resetting the CPU module, the test starts automatically in approximately one second. The RUN LED flashes during the test. (Set the CPU module in the STOP state.)

#### 3. Checking results of hardware test

- When the result is normal

The RUN LED turns ON and the ERR LED turns OFF.

- When the result is abnormal

The RUN LED turns ON and the ERR LED turns ON.

#### 4. Completing hardware test

- When the result is normal

Perform an Self-loopback test. (  Page 494 Self-loopback test)

Start data communication with the target device according to the following procedure.

- Configure the parameter settings with Engineering tool. (  Page 454 PARAMETER SETTING)
- Turn OFF the power for the station with C24, and connect the cable to communicate with the target device.
- Turn ON the power for the station with C24.
- When the result is abnormal

Check error contents on the items below on the "Intelligent Function Module Monitor" screen of Engineering tool.

Check the error descriptions on the screens by bit-decoding the monitored value (16-bit integer). Each bit corresponds to the following error description.

| Buffer memory to be monitored |                   |                   | Description when corresponding bit is ON |                            | Corrective action                                                                                                                                                                |
|-------------------------------|-------------------|-------------------|------------------------------------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit position                  | Address           |                   |                                          |                            |                                                                                                                                                                                  |

\*1 When an error occurs even after performing the test again, please consult your local Mitsubishi representative.

## Self-loopback test

The self-loopback test is a test to check the communication between C24 and the CPU module and the operation of the data transmit/receive function of C24.

Perform the self-loopback test according to the procedure below.

### Operating procedure

#### 1. Connecting cable

- Connect cables to two interfaces as follows:

For the RS-232 interface, connect cables within the connector and install it to the interface.

For the RS-422/485 interface, connect cables on the terminal block.

RS-232 interface (D-Sub 9P female)

| C24         |         | Cable connection |
|-------------|---------|------------------|
| Signal name | Pin No. |                  |
| CD(DCD)     | 1       |                  |
| RD(RXD)     | 2       |                  |
| SD(TXD)     | 3       |                  |
| ER(DTR)     | 4       |                  |
| SG          | 5       |                  |
| DR(DSR)     | 6       |                  |
| RS(RTS)     | 7       |                  |
| CS(CTS)     | 8       |                  |
| CI(RI)      | 9       |                  |

RS-422/485 interface

| C24         | Cable connection                                                                    |
|-------------|-------------------------------------------------------------------------------------|
| Signal name |                                                                                     |
| SDA         |  |
| SDB         |                                                                                     |
| RDA         |  |
| RDB         |                                                                                     |
| SG          |                                                                                     |
| SLD         |                                                                                     |
| FG          |                                                                                     |

#### 2. Test mode setting ( Page 454 PARAMETER SETTING)

- Set the test mode setting to "Self-loopback test".
- Configure all of the transmission settings for the two interfaces according to the transmission specifications.
- Set the CPU module to the STOP state, and write the parameters.

#### 3. Performing the self-loopback test

- By restarting or resetting the CPU module, the test starts automatically in approximately one second. The RUN LED flashes during the test. (Set the CPU module in the STOP state.)
- C24 performs the following tests in sequence and repeat them (one test cycle takes approximately one second).  
C24 ends the test when all test results become abnormal.

| Test item                                           | Description                             | LED flashes during the test |
|-----------------------------------------------------|-----------------------------------------|-----------------------------|
| Checking communication with CPU module              | Read and check the CPU module model.    | RUN LED                     |
| Checking the transmit/receive function of interface | Send and receive data by changing data. | SD LED<br>RD LED            |

#### 4. Checking the results of self-loopback test

- When the result is normal

This test is performed repeatedly. When the ERR LED is OFF, C24 is operating normally.

- When the result is abnormal

The ERR LED turns ON.

## 5. Completing self-loopback test

- When the result is normal

Start data communication with the target device.

- Configure the parameter settings with Engineering tool. (🔗 Page 454 PARAMETER SETTING)
- Turn OFF the power for the station with C24, and connect the cable to communicate with the target device.
- Turn ON the power for the station with C24.

- When the result is abnormal

Check an error description on the "Intelligent Function Module Monitor" screen of Engineering tool.

Check the error descriptions on the screens by bit-decoding the monitored value (16-bit integer). Each bit corresponds to the following error description.

| Buffer memory to be monitored |                   |                   | Description when corresponding bit is ON                              | Corrective action                                                                                                        |
|-------------------------------|-------------------|-------------------|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Bit position                  | Address           |                   |                                                                       |                                                                                                                          |
|                               | CH1 side: Un\G513 | CH2 side: Un\G514 |                                                                       |                                                                                                                          |
| b0 to b3                      | —                 |                   | —                                                                     | —                                                                                                                        |
| b4                            | C/N               | —                 | Error occurred on the CPU module.                                     | Remove the cause of error in the CPU module.                                                                             |
|                               |                   |                   | The power supply capacity is insufficient.                            | Review the power supply capacity.                                                                                        |
|                               |                   |                   | Module is not mounted correctly.                                      | Mount the module properly.                                                                                               |
|                               |                   |                   | Error on the base unit, extension cable, CPU module, or C24 occurred. | Check for each module and remove the cause of the error.<br>Reconnect the cable correctly.<br>Mount the module properly. |

# Loopback test

A loopback test is a test to perform communication with the loopback test function of the MC protocol in order to check the connection between C24 and the target device, the communication function of each device, and the operation of the communication program of the target device.

## Operating procedure

### 1. Connecting C24 to a target device

Turn OFF the power for the station with C24 and connect a communication cable to communicate with the target device in order to perform data communication using the MC protocol.

 MELSEC iQ-R Serial Communication Module User's Manual(Startup)

### 2. Setting the parameter with Engineering tool

- Configure the parameter settings with Engineering tool, and write the parameters to the CPU module in order to perform data communication using the MC protocol.
- The following shows an example of the settings when performing the loopback test on the interface on the CH1 side.

| Parameter setting item         |                   | Setting contents       |
|--------------------------------|-------------------|------------------------|
| Communication protocol setting |                   | MC protocol (Format 1) |
| Communication speed setting    |                   | 9600 bps               |
| Transmission setting           | Operation setting | Independent operation  |
|                                | Data bit          | 7                      |
|                                | Parity bit        | Yes                    |
|                                | Odd/even parity   | Odd                    |
|                                | Stop bit          | 1                      |
|                                | Sum check code    | Yes                    |
|                                | Online change     | Disable                |
|                                | Setting change    | Disable                |
| Station number setting         |                   | 0                      |

### 3. Performing loopback test

- By restarting or resetting the CPU module, the communication is enabled in approximately one second. (Set the CPU module in the STOP state.)
- Create a program for the loopback test on the target device side and send a command message as shown below to C24.

For communication test with 1C frame: TT command

For communication test with 2C/3C/4C frame\*1: 0619 command

\*1 When performing communication test with 2C/3C/4C frame, refer to the following manual.

 MELSEC Communication Protocol Reference Manual

An example of control procedure when the TT command is used in the loopback test (station number: 00, sum check code: Yes) is as shown below.

#### 4. Checking loopback test result

Check for the target device side whether the data in the character area received from C24 in response to the data sent by the target device matches the data in the character area sent by the target device. (C24 sends back to the target device the received data, as is.)

- When the result is normal

The data in the character area that C24 sent back to the target device matches the one the target device had sent.

- When the result is abnormal

The data in the character area that C24 sent back to the target device does not match the one the target device had sent.

#### 5. Completing loopback test

- When the result is normal

Configure the parameter settings with Engineering tool in accordance with the function to be used, and turn ON the power for the station with C24 to start data communication.

- When the result is abnormal

Check the items below, and take corrective actions.

| Item                                         | Corrective action                                                                                                                                                      |

## 29.2 How to Clear Programmable Controller CPU Information

This section explains how to clear the programmable controller CPU information.

### Programmable controller CPU information

- This is the information about the access target CPU module type used for communications using MC protocol and the MODBUS slave function.  
C24 obtains this information from the access target CPU module at the time of initial access, and stores it.  
When accessing for the second time or later, the processing to access to the CPU module get faster in accordance with this information.
- The programmable controller CPU information is cleared in the following cases:  
When the programmable controller is powered OFF → ON, or when the CPU module is reset  
When the programmable controller CPU information clear request is executed

### If the programmable controller CPU information has not been correctly obtained

The following problems may occur:

- Accessible device range become narrowed. (Error code: 7140H)
- Some of commands and/or devices cannot be used. (Error code: 7142H, 714DH),  
etc.

In the above case, execute the programmable controller CPU information clear request.

#### Restriction

If initial access is made at startup of the access target CPU module or while the network is unstable, the programmable controller CPU information may not be correctly acquired.

### Operation of the programmable controller CPU information clear request

- Write "4C43H" to the 'Programmable controller CPU information clear request' (Un\G128). (Set by the user)

- The programmable controller CPU information clear processing of C24 is performed.\*1
- Upon completion of the clear processing, "0000H" is written to the 'Programmable controller CPU information clear request' (Un\G128). (Set by the C24)

\*1 The 'Transmission sequence status' (Un\G597/613) is also initialized.

## Executing the programmable controller CPU information clear request

1. In the "Intelligent Function Module Monitor" screen, set "4C43H" to the 'Programmable controller CPU information clear request' (Un\G128).
2. Check the 'Programmable controller CPU information clear request' (Un\G128) turns to "0000H" with the Buffer Memory Batch Monitor function.

### Precautions

- Execute the programmable controller CPU information clear after communication with the target device is stopped. In addition, do not perform data communication with the target device during the programmable controller CPU information clear processing. (If any data are received from the target device during the programmable controller CPU information clear processing, the data will be discarded.)
- When a modem is connected, cut off the line linked with the target device before executing the programmable controller CPU information clear. (The line is cut off at execution of the programmable controller CPU information clear.)
- Do not execute the UINI instruction during the programmable controller CPU information clear processing. If the programmable controller CPU information clear is attempted during execution of the UINI instruction, the clear processing will be executed after completion of the UINI instruction.

## 29.3 Troubleshooting by Symptom

The troubleshooting for any troubles generated during communication between C24 and the target device by trouble symptom are as shown below.

When any trouble occurs, check on the C24 condition at first, and check the relevant item in the table below.

| Symptom                                                                                          | Symptom description                                                                                                                      | Protocol |     |    |    |    |   |
|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|----------|-----|----|----|----|---|
|                                                                                                  |                                                                                                                                          | MC       | Non | Bi | Pd | MD | S |

\*1 For details on LED status, refer to the following manual.

☞ MELSEC iQ-R Serial Communication Module User's Manual(Startup)

\*2 For details on how to check the hardware information communication error, refer to the following section.

☞ Page 483 Checking error status

\*3 If an error occurs while performing data communication using the modem function, first check the following items and determine whether or not the error is caused by the modem/TA connection.

If an error relating to the modem function occurred, take necessary corrective actions according to the reference sections shown below:

- Check of the ON/OFF status of current input/output signals on C24
- Check of the error code storage status for the modem function
- Check of the ON/OFF status of the DR terminal on the modem/TA (Refer to the instruction manual for modem/TA.)

## Precautions

The considerations for data communication with the target device via either of C24 interfaces are shown below:

- When powering up the C24 side or the target device side, data reception error may occur at the target device side being connected.
- When the connected target device side starts up during data transmission, the data reception error occurs at the target device side.
- When the ERR LED on C24 turns ON due to data reception error, turn OFF the LED as necessary. (☞ Page 492 Turning OFF the ERR LED and initializing the error codes)  
Also, when a data reception error occurs on the target device side, take corrective actions in accordance with the instruction manuals for the target device.

### ■Error occurred on the C24 side

Handle the error as shown below when data reception error occurs on C24 side.

- For communications using the MC protocol  
C24 will disregard the received data or return a response message indicating an abnormal completion if it detects a data reception error after receiving the head data of the command message in the set format.  
If the data reception error is detected before the head data of the command message in the set format is received, the received data will be disregarded.
- When communicating using the predefined protocol  
C24 will store the error code in the 'Data reception result' (Un\G600/616) when a data reception error occurs.  
Reception error can be also checked with the send/receive data monitoring function.  
Take appropriate measures such as detecting a data reception error or clearing the received data, if necessary.  
For more details on the send/receive data monitoring function, refer to the following section.  
(☞ Page 419 USING SEND/RECEIVE DATA MONITORING FUNCTION)
- When communicating using nonprocedural protocol  
C24 will turns ON the reception abnormal detection (X4/XB) when it detects a data reception error.  
Take appropriate measures such as detecting a data reception error or clearing the received data, if necessary.  
(☞ Page 68 Reception error detection and check methods, ☞ Page 70 Receive data clear)
- For communications using bidirectional protocol  
C24 will return a response message indicating an abnormal completion if it detects a data reception error after receiving the head data of the communication message for the bidirectional protocol.  
If the reception error is detected before the head data of the communication message for the bidirectional protocol is received, the received data will be disregarded.
- When communicating using the MODBUS slave function  
C24 will disregard received data if it detects a CRC or LRC error during data reception.  
When using RTU mode, send request data as continuous data from a connected target device.  
If no-reception time occurs for 1.5 character times or more before all data is received, C24 will disregard received data and regard the head data of data received next as a new address field.  
When using ASCII mode, if there is no-reception time for one second or more, an error will occur.
- When communicating using the simple CPU communication function  
C24 will discard received data if it detects a reception error during data reception.

### ■Meaning of abbreviations in "Protocol" column

MC: MC protocol

Non: Nonprocedural protocol

Bi: Bidirectional protocol

Pd: Predefined protocol

MD: MODBUS (slave function)

S: Simple CPU communication

## SD LED does not flash even after a send request was made

## When a normal completion response message cannot be received

The following explains how to take corrective actions when a normal completion response message cannot be received upon command message transmission.

### ■An abnormal completion response message is received

When a target device received an abnormal completion response message in response to the sent command message, take corrective action according to the error code in the response message. (  Page 519 Error Code List)

When the following problem occurs at the time of access to other station CPU module, clear the programmable controller CPU information and retry. (  Page 498 How to Clear Programmable Controller CPU Information)

- Accessible device range became narrow. (Error code: 7140H)
- Some of commands and/or devices cannot be used (Error code: 7142H, 714DH) etc.

### ■Response messages cannot be received

Change the setting value for the response monitoring time (timer 1, 5 seconds by default). (  Page 454 PARAMETER SETTING)

If response messages still cannot be received even after changing the setting value, check the communication protocol setting for the relevant interface, the ON status of the indicator LED, and the connection cable.

### ■The first part of a response message cannot be received

Increase the setting value of the transmission wait time (the default value is 0 ms). (  Page 454 PARAMETER SETTING)

If response messages still cannot be received even after increasing the setting value, reducing the processing time from the end of transmission processing to the start of reception processing on the target device side is required.

## Undecodable data are transmitted or received

## A verification mismatch occurs in the module extended parameter even though there is no mismatch

| Symptom                                                                                                                                                                                                                                                                     | Cause                                                                                                           | Corrective action                                                                                                                                                                                                                                            | MC | Non | Bi | Pd | MD | S |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|----|----|----|---|
| After writing module extended parameters including the simple CPU communication setting to a programmable controller, a verification mismatch occurs in the module extended parameter even though there is no mismatch in verification of the programmable controller data. | The programmable controller data is verified by using a project created in GX Works3 Version 1.105K or earlier. | Upgrade GX Works3 to Version 1.110Q or later, and open the simple CPU communication setting screen from the module extended parameter of RJ71C24(-R2/R4) and click the [OK] button to save the project. Then, verify the programmable controller data again. | —  | —   | —  | —  | —  | ○ |

## 29.4 Error Code List

This section explains the error codes, error contents, and corrective actions for errors may occur during data communication and when using the modem function.

The signal name in the table shows the LED lighting status and communication error status stored in the 'CH□ side LED lighting status, communication error status' (Un\G513/514) when error occurs.

The CH□ side LED lighting status and communication error status can be checked with the System Monitor function or the Intelligent Function Module Monitor function of Engineering tool.

Note that "NAK" turns ON for errors which occur by the MC protocol communication and the signal name is not indicated.

For the error code when communicating using 1C frame, refer to the following manual.

 MELSEC-L Serial Communication Module User's Manual (Basic)

The meanings of abbreviations in the table are as follows:

- MC: MC protocol
- Non: Nonprocedural protocol
- Bi: Bidirectional protocol
- Pd: Predefined protocol
- MD: MODBUS (slave function)
- S: Simple CPU communication

| Error code<br>(hexadecimal) | Error                                                         | Description                                                                                                                                                                                                                                                                                                                                                       | Signal<br>name | Corrective action                                                                                                                                                                                                                                                                                                                                                       | Protocol              |                       |                       |                       |                       |                       |

\*1 An error code when the target CPU is one of MELSEC-A series.

## Corrective actions for system error

1. Check if the C24, the power module, and the CPU module are mounted correctly.
2. Check if the environment of the C24 usage is within the range of the general specifications for the CPU module.
3. Check if the power supply capacity is sufficient.
4. Check if the hardware of the C24 and the CPU module is normal according to the respective module manual. In case of a malfunction, please contact your local Mitsubishi representative for service.
5. If the problem is still not solved, please consult your local Mitsubishi representative, explaining a detailed description of the problem.

## 29.5 Event History List

The table below shows the events saved by C24.

| Event code | Event type | Description                                   | Cause                                                                            |
|------------|------------|-----------------------------------------------|----------------------------------------------------------------------------------|
| 10200      | Security   | Remote password lock                          | The remote password is locked.                                                   |
| 10201      |            | Remote password unlock                        | The remote password is unlocked.                                                 |
| 10202      |            | Failure of remote password unlock             | The remote password was failed to be unlocked.                                   |
| 27000      | Operation  | Transmission sequence initialization          | The transmission sequence used by the MC protocol was initialized.               |
| 27001      |            | Programmable controller CPU information clear | The programmable controller CPU information clear request was executed.          |
| 27002      |            | Error clear request                           | The error clear request was executed.                                            |
| 27003      |            | Mode switching request                        | The mode switching request was executed.                                         |
| 27004      |            | Modem initialization request                  | The modem initialization request was executed.                                   |
| 27005      |            | Connection request                            | The connection request for the modem was executed.                               |
| 27006      |            | Modem disconnection request                   | The disconnection request for the modem was executed.                            |
| 27007      |            | Parameter initialization request              | The parameter initialization request was executed.                               |
| 27008      |            | Connection request from MELSOFT products      | By MELSOFT connection, the access via Serial communication module was performed. |
| 27010      |            | Module extended parameter open error          | Opening module extended parameter in CPU module has failed.                      |
| 27011      |            | Module extended parameter read error          | Reading module extended parameter in CPU module has failed.                      |

## 29.6 MODBUS Exception Code List

Exception codes are error codes common to the MODBUS protocol that are stored in a response message when a slave returns an abnormal response to a request message from a master device.

When a target device receives an exception code from a C24, refer to the following table to take a corrective action.

If processing on a C24 is completed abnormally, an exception code is stored in the error log area (Un\G31998 to 32255) of the buffer memory.

The following table lists the exception codes.

| Code | Name                                    | Description                                                                                                                     | Corrective action                                                                                                                  |                                                                                                                                                  |

| 01h  | Illegal Function                        | The slave station received an unsupported function code.                                                                        | Check function codes supported by the C24, and modify the request message to be issued.                                            | —                                                                                                                                                |
| 02h  | Illegal Data Address                    | The specified address of the MODBUS device is erroneous.                                                                        | Check the MODBUS device type and size supported by the C24, and correct the specified address in the request message to be issued. | —                                                                                                                                                |
| 03h  | Illegal Data Value                      | A value contained in the data field of the request message is incorrect.                                                        | Review the data field of the issued request message.                                                                               | —                                                                                                                                                |
| 04h  | Slave Device Failure                    | An unrecoverable error occurred while the slave station was attempting to perform the requested action.                         | Review the data field of the issued request message.                                                                               | Remove the cause of the error occurred on the C24 side.<br>Refer to the error log of the C24, and solve the problem according to the error code. |
| 05h  | Acknowledge                             | As the slave station is executing another processing, a long duration of time is required to complete the requested processing. | Not issued by the C24.                                                                                                             |                                                                                                                                                  |
| 06h  | Slave Device Busy                       | As the slave station is executing another processing, the requested processing cannot be executed.                              | Not issued as a response message by the C24.                                                                                       |                                                                                                                                                  |
| 07h  | NAK Error                               | The requested program function cannot be executed on a slave station.                                                           |                                                                                                                                    |                                                                                                                                                  |
| 08h  | Memory Parity Error                     | A parity error was detected on a slave station during access to the extension file register.                                    | Not issued by the C24.                                                                                                             |                                                                                                                                                  |
| 0Ah  | Gateway Path Unavailable                | The gateway device is not available for use.                                                                                    |                                                                                                                                    |                                                                                                                                                  |
| 0Bh  | Gateway Target Device Failed To Respond | There is no response from the slave station connected ahead of the gateway device.                                              |                                                                                                                                    |                                                                                                                                                  |

# APPENDIX

## Appendix 1 Module Label

The input/output signal and buffer memory of C24 can be set by using module label.

### Module label configuration

A name of module label is defined in the configuration below:

"Instance name"\_"Module number"."Channel number"."Label name"

"Instance name"\_"Module number"."Label name"

"Instance name"\_"Module number"."Channel number"."Label name"\_D

"Instance name"\_"Module number"."Label name"\_D

**Ex.**

C24\_1.stnCH1.uSet\_ReceivedDataCount\_Reception\_D

#### ■Instance name

The instance name for RJ71C24(-R2/R4) is "C24".

#### ■Module number

A module number is a number starting from 1, which is added to identify a module that has the same instance name.

#### ■Channel number

A channel number is a number added to the module label corresponding to a buffer memory other than the CH1/CH2 common area.

For module label corresponding to a buffer memory other than the CH1/CH2 common area, the following content is added as the channel number.

| Channel number | Content to be added |
|----------------|---------------------|
| CH1            | stnCH1              |
| CH2            | stnCH2              |

#### ■Label name

This is a module unique label name.

#### ■\_D

This indicates that the module label is for direct access. Without this symbol means a label for refresh. There are some differences between refresh and direct access as shown below.

| Type          | Description                                                                                                                                                                           | Access timing                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| Refresh       | Values written to/read from a module label are reflected to the module in batch at the time of refresh. This shortens program execution time.                                         | At the time of refresh                                  |
| Direct access | Values written to/read from a module label are immediately reflected to the module. Although the program execution time is longer than refresh, the responsiveness will be increased. | At the time of writing to/<br>reading from module label |

# Appendix 2   Input/Output Signal List

---

This section explains the input/output signals of C24.

The input/output signal assignments in the table below are when the start I/O number of C24 is '0000'.

The devices starting with X indicate input signals from a C24 to CPU module.

The devices starting with Y indicate output signals from a CPU module to C24.

Do not output (turn ON) the signals of "Use prohibited" in the input/output signal list shown below.

If any of the "Use prohibited" signals is output, the programmable controller system may malfunction.

---

## Input signals

| Device number     | Signal name                                   | Reference                                                                              |
|-------------------|-----------------------------------------------|----------------------------------------------------------------------------------------|

\*1 The device does not turn ON/OFF by executing a dedicated instruction when using a function that corresponds to the input signal.

\*2 The device turns ON/OFF by executing a dedicated instruction when using a function that corresponds to the input signal.  
(ON→OFF: Data read completion)

\*3 The 'CH□ Switching mode' (X6/XD) turns ON when the following function is performed.

· Mode switching, transmission sequence initialization, reception data clear (by buffer memory), user frame use enable/disable designation, UINI instruction, programmable controller CPU information clear

While the 'CH□ Switching mode' (X6/XD) is ON, do not issue a communication request to a target interface.

(The transmission/reception processing of C24 is stopped while the 'CH□ Switching mode' (X6/XD) is ON.)

\*4 The C ERR LED of the same channel also turns ON when an error occurs.

'CH□ Error occurrence' (XE/XF) turns OFF when 'Error initialization request' (YE) turns ON or the data transmission/reception processing is performed normally.

\*5 'Predefined protocol ready' (X1D) is a signal that turns ON when predefined protocol communication becomes ready.

\*6 Module READY is a signal that sends a signal of the applicability of accessing to C24 from the CPU module.

Use it as an interlock signal for a program.

\*7 Restart the CPU module when the watchdog timer error is turned ON.

If the error still occurs after restarting, refer to the following section and take corrective actions.

☞ Page 508 RUN LED turns OFF

# Appendix 3 Buffer Memory

The buffer memory is the memory of C24 used for storing data (setting values, monitoring values, etc.) transmitted to or received from the CPU module.

Initial values are set to the buffer memory.

When changing the initial values, set the parameters with Engineering tool.

For details, refer to the following section.

 Page 454 PARAMETER SETTING

## Configuration of buffer memory

A buffer memory consists of a user area and a system area as shown below.

### ■User area

- User area is an area where a user can read/write data.
- The user area consists of areas for storing setting values for data communication, for actual data communication, and for storing communication status and communication error information.
- Read/write data from/to the user area in accordance with the instructions in the corresponding reference section.

### ■System area

System area is an area used by the C24 system.

## Buffer memory assignment list

A buffer memory is configured with 16 bits per address.

Names, default values, etc. of each address of the buffer memory are as shown below.

 Page 550 Buffer memory list

### ■Meaning of abbreviations in "Protocol" column

MC: MC protocol

Non: Nonprocedural protocol

Bi: Bidirectional protocol

Pd: Predefined protocol

MD: MODBUS (slave function)

S: Simple CPU communication

### ■Meaning of symbols in "Protocol" column

The following symbols are assigned to protocols related to the setting values of a corresponding area and to areas used for control by user settings.

R, W: An area where data can be read/written from/to the CPU module and an target device.

R: An area where data can only be read from the CPU module and an target device.

—: System area used by the system or area not used by the corresponding protocol.

## Precautions

- Do not write data in the "System area" of the buffer memory.  
If data is written to any of the system areas, the programmable controller system may malfunction.  
The system area exists in the user area partially, therefore, take caution when reading from/writing to the buffer memory.
- To use the dedicated instructions, change the following initial settings (default values) for data communications by setting parameters with an Engineering tool, or by executing the CSET instruction in the program.

| Initial setting                                           |                                                                | Setting item                                                                                                                              |
|-----------------------------------------------------------|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|

## ■Addresses of setting No.2 diagnostic information and later

Each address of setting No.2 diagnostic information and later can be calculated with the following formula:

- Address of the buffer memory corresponding to setting No.1 + ((Target setting number - 1) × 24)

**Ex.**

The address of 'Latest error code' of setting No.512 is as follows:

- $32892 + ((512 - 1) \times 24) = 45156$

## Monitoring device areas for the programmable controller CPU monitoring function

### ■CH1 side buffer memory address: decimal (hexadecimal)

# Appendix 4 Dedicated Instructions

Dedicated instructions are used to simplify programming when using intelligent function module functions.

For details, refer to the following manual.

📖 MELSEC iQ-R Programming Manual (Module Dedicated Instructions)

## Dedicated instruction list

### List of dedicated instruction

The following table lists the dedicated instructions explained.

| Purpose                                                                   | Dedicated instruction | Function overview                                                                                                                                                     |
|---------------------------------------------------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| On-demand function transmission                                           | ONDEMAND*1            | Sends data using the on-demand function of MC protocol.                                                                                                               |
| Predefined protocol function                                              | CPRTCL                | Executes the protocol setting data registered using the Predefined protocol support function of Engineering tool.                                                     |
| Nonprocedural protocol communication                                      | OUTPUT*1              | Transmits data for the designated data count.                                                                                                                         |
|                                                                           | INPUT*1               | Reads received data.                                                                                                                                                  |
| Bidirectional protocol communication                                      | BIDOUT*1              | Transmits data for the designated data count.                                                                                                                         |
|                                                                           | BIDIN*1               | Reads received data.                                                                                                                                                  |
| Communication status confirmation                                         | SPBUSY                | Reads the status of data transmission/reception using the dedicated instruction.                                                                                      |
| Data transmission/reception                                               | BUFRCVS*1             | Receives data by an interrupt program using nonprocedural or bidirectional protocol communication.                                                                    |
|                                                                           | PRR*1                 | Transmits data with the user frame according to the contents defined in the send user frame designation area in data communications using the nonprocedural protocol. |
| Receive data clear                                                        | CSET                  | Performs the receive data clear without stopping the transmission processing in data communications using the nonprocedural protocol.                                 |
| Programmable controller CPU monitoring function                           |                       | Registers/cancels programmable controller CPU monitoring in order to use the programmable controller CPU monitoring functions.                                        |
| Setting the units of send/receive data quantity                           |                       | Sets the unit (word/byte) of data quantity to be sent and received.                                                                                                   |
| User frame registration to flash ROM (registration/reading of user frame) | PUTE                  | Registers a user frame.                                                                                                                                               |
|                                                                           | GETE                  | Reads a user frame.                                                                                                                                                   |
| Mode switching                                                            | UINI                  | Changes the mode, transmission specifications, and host station No. of C24.                                                                                           |

\*1 To change the following setting values of the buffer memory used by the dedicated instructions, use Engineering tool or execute the CSET instruction (initial setting) before starting data communication. (📖 MELSEC iQ-R Programming Manual (Module Dedicated Instructions))

·'Word/byte units designation' (Un\G150/310)

·'Buffer memory start address designation' (Un\G160/321)

·'Send buffer memory start address designation' (Un\G162/322)

·'Send buffer memory length designation' (Un\G163/323)

·'Receiving buffer memory start address designation' (Un\G166/326)

·'Receive buffer memory length designation' (Un\G167/327)

The dedicated instructions are executed base on the setting values of the buffer memory at the module startup or those which were changed by the CSET instruction (initial setting).

### Precautions

Do not change data (control data, request data, etc.) designated by a dedicated instruction until the execution of that instruction is completed.

# Appendix 5    Operation Image and Data Structure of Predefined Protocol

## Operation image of each communication type of protocol

In the predefined protocol function, communication with target devices is performed through the communication type "Send only", "Receive only", or "Send & receive". This section explains the respective operation images.

### When communication type is "Send Only"

The specified packet is transmitted once.

The operation image of "Send only" is as follows.

#### ■Normal completion

#### ■Error completion (transmission monitoring timeout error)

Example of setting

Standby time: 0, Number of send retries: 0, Monitoring time: other than 0

**When communication type is "Receive Only"**

When data are received from the target device, the process completes when the received data matches the receive packet and the receiving process is performed.

The operation image of "Receive only" is as follows.

**■Normal completion**

## ■Error completion (receive wait timeout error)

### Point

- When variables are included in receive packet elements, variable parts are not verified.
- When more than one receive packet is specified, received data is verified with the receive packet information of the first registered packet in the order of registration. The receive processing is performed once received data match one of the receive packet number, and further verification is not performed.
- The receive packet number which is matched as the result of the verification is stored in the control data of the dedicated instruction (CPRTCL instruction).

When communication type is "Send & Receive"

A packet is sent once, and the status changes to the data receive wait stat after the transmission completes normally. Then, data is received from the target device, and the process completes when the received data matches the receive packet and the receiving process is performed.

The operation image of "Send & receive" is as follows.

Normal completion

## ■Error completion (receive wait timeout error)

### Point

- When variables are included in receive packet elements, variable parts are not verified.
- When more than one receive packet is specified, received data is verified with the receive packet information of the first registered packet in the order of registration. The receive processing is performed once received data match one of the receive packet number, and further verification is not performed.
- The receive packet number which is matched as the result of the verification is stored in the control data of the dedicated instruction (CPRTCL instruction).

# Verification operation of receive packet

The following shows C24 operation when data that are different from the specified receive packet are received. Receive data prior to the different data is discarded. Data is compared again from the start of the receive packet, and once the data matches the receive packet, the data receiving operation is processed.

# Data examples of packet elements

This section explains the processing procedures and practical data examples of elements that can be placed in a packet.

## Length

### ■Processing procedure

C24 processes length according to the following procedure.

### ■Data example

The following is an example in the case where the calculated value of length is 258 bytes in decimal (258 is 102H in hexadecimal).

- Data flow is "Forward direction"

| Code type         | Data length <sup>*1</sup> |                |                     |                          |
|-------------------|---------------------------|----------------|---------------------|--------------------------|
|                   | 1 byte                    | 2 bytes        | 3 bytes             | 4 bytes                  |
| ASCII hexadecimal | "2" (32H)                 | "02" (30H 32H) | "102" (31H 30H 32H) | "0102" (30H 31H 30H 32H) |
| ASCII decimal     | "8" (38H)                 | "58" (35H 38H) | "258" (32H 35H 38H) | "0258" (30H 32H 35H 38H) |
| HEX               | 02H                       | 0102H          | 000102H             | 00000102H                |

\*1 Values in '( )' indicate ASCII code.

- Data flow is "Reverse direction"

| Code type         | Data length <sup>*1</sup> |                |                     |                          |
|-------------------|---------------------------|----------------|---------------------|--------------------------|
|                   | 1 byte                    | 2 bytes        | 3 bytes             | 4 bytes                  |
| ASCII hexadecimal | —                         | "20" (32H 30H) | "201" (32H 30H 31H) | "2010" (32H 30H 31H 30H) |
| ASCII decimal     | —                         | "85" (38H 35H) | "852" (38H 35H 32H) | "8520" (38H 35H 32H 30H) |
| HEX               | —                         | 0201H          | 020100H             | 02010000H                |

\*1 Values in '( )' indicate ASCII code.

- Data flow is "Byte swap"

| Code type         | Data length <sup>*1</sup> |         |         |                          |
|-------------------|---------------------------|---------|---------|--------------------------|
|                   | 1 byte                    | 2 bytes | 3 bytes | 4 bytes                  |
| ASCII hexadecimal | —                         | —       | —       | "1020" (31H 30H 32H 30H) |
| ASCII decimal     | —                         | —       | —       | "2085" (32H 30H 38H 35H) |
| HEX               | —                         | —       | —       | 00000201H                |

\*1 Values in '( )' indicate ASCII code.

■Calculating range

The following shows specification examples of the calculating range of Length.

Example 1: Calculating range when 1 and n are specified as the start and the end respectively.

Example 2: Calculating range when 3 and n-2 are specified as the start and the end respectively.

Example 3: Calculating range when 3 and n are specified as the start and the end respectively.

Non-conversion variable

■Processing procedure

C24 processes non-conversion variable according to the following procedure.

A

## ■Data example

- The following table shows data to be stored in the data storage area when the string of send data is 'ABCD'.  
(Reference: A=41H, B=42H, C=43H, and D=44H in ASCII code)

| Item                                   | Description             |                      |                                              |                                              |
|----------------------------------------|-------------------------|----------------------|----------------------------------------------|----------------------------------------------|
| Fixed length/Variable length           | Fixed length            |                      |                                              |                                              |
| Data length                            | 4 bytes                 |                      |                                              |                                              |
| Start address of data storage area     | D0                      |                      |                                              |                                              |
| Unit of stored data                    | Lower byte + Upper byte |                      | Lower bytes only                             |                                              |
| Byte swap                              | Disable                 | Enable               | Disable                                      | Enable                                       |
| Data to be stored in data storage area | D0=4241H<br>D1=4443H    | D0=4142H<br>D1=4344H | D0=0041H<br>D1=0042H<br>D2=0043H<br>D3=0044H | D0=0042H<br>D1=0041H<br>D2=0044H<br>D3=0043H |

- The following table shows data to be stored in the data storage area when the string of send data is 'EFG'.  
(Reference: E=45H, F=46H, and G=47H in ASCII code)

| Item                                   | Description             |                      |                                                    |                                                    |
|----------------------------------------|-------------------------|----------------------|----------------------------------------------------|----------------------------------------------------|
| Fixed length/Variable length           | Fixed length            |                      |                                                    |                                                    |
| Data length                            | 3 bytes                 |                      |                                                    |                                                    |
| Start address of data storage area     | D0                      |                      |                                                    |                                                    |
| Unit of stored data                    | Lower byte + Upper byte |                      | Lower bytes only                                   |                                                    |
| Byte swap                              | Disable                 | Enable               | Disable                                            | Enable                                             |
| Data to be stored in data storage area | D0=4645H<br>D1=0047H    | D0=4546H<br>D1=4700H | D0=0045H<br>D1=0046H<br>D2=0047H<br>D3= (any data) | D0=0046H<br>D1=0045H<br>D2=0047H<br>D3= (any data) |

## Conversion variable

### ■ Processing procedure

C24 processes conversion variable according to the following procedure.

- When "Conversion" is 'HEX → ASCII hexadecimal' or 'ASCII hexadecimal → HEX'

#### Blank-padded characters

When transmitting data, upper digits are filled with the data specified in "Blank-padded character" when the number of digits is less than that specified in "Number of Send Digits of Data".

When receiving data, either '0' or '\_' (space) is processed as a blank-padded character regardless of the specification in "Blank-padded character".

#### Ex.

Setting of "Number of Send Digits of Data" is '6' ('\_' indicates a space character in the table)

| Received data | Operation of C24                                            |
|---------------|-------------------------------------------------------------|
| 000120        | Considers the first 3 digits as blank-padded characters.    |
| _ _ 0120      | Considers the first 3 digits as blank-padded characters.    |
| 0 _ 0120      | Considers the first 3 digits as blank-padded characters.    |
| _ _ _ 120     | Considers the first 3 digits as blank-padded characters.    |
| 00012 _       | Considers it to be an ASCII → BIN conversion error (7F20H). |
| _ _ _ 12 _    | Considers it to be an ASCII → BIN conversion error (7F20H). |
| 0001 _ 0      | Considers it to be an ASCII → BIN conversion error (7F20H). |

- When "Conversion" is "HEX → ASCII Decimal" or "ASCII Decimal → HEX"

## ■Data example

The following table shows send data when a packet consists of [Header], [Conversion variable], [Terminator] and data stored in the data storage area is D0=837 (0345H), D1=18 (0012H). (Reference: 120345H =1180485 in decimal form)

### • Data example 1

<sup>\*1</sup> ' \_ ' indicates a blank.

## Check code

### ■Processing procedure

C24 processes check code according to the following procedure.

1. Calculates value according to the selection of "Processing method".
2. When "Complement calculation" is 'One's complement' or 'Two's complement', performs a 2-word-wise complement operation on the value calculated in the above 1.
3. When "Code type" is 'ASCII decimal', extracts the lowest one word from the value calculated in the above 2, and performs the hexadecimal to decimal conversion.

### ■Calculation procedure for horizontal parity

The following show procedures for calculating horizontal parities using the following sample data.

|                       |     |     |     |     |     |     |     |     |                   |
|-----------------------|-----|-----|-----|-----|-----|-----|-----|-----|-------------------|
| STX                   | "R" | "J" | "7" | "1" | "C" | "2" | "4" | ETX | Horizontal parity |
| ← Calculating range → |     |     |     |     |     |     |     |     |                   |

For the packet shown above

```

"R" (52H) 0101 0010
XOR
"J" (4AH) 0100 1010 = 0001 1000
XOR
"7" (37H) 0011 0111 = 0010 1111
XOR
"1" (31H) 0011 0001 = 0001 1110
XOR
"C" (43H) 0100 0011 = 0101 1101
XOR
"2" (32H) 0011 0010 = 0110 1111
XOR
"4" (34H) 0011 0100 = 0101 1011
XOR
ETX (03H) 0000 0011 = 0101 1000 (Binary)
Horizontal parity = 58 (Hexadecimal)
  
```

■ Data flow: Forward direction

- "No Complement Calculation" is designated (58H in hexadecimal is 88 in decimal)

| Code type         | Data length* <sup>1</sup> |                |                     |                          |
|-------------------|---------------------------|----------------|---------------------|--------------------------|
|                   | 1 byte                    | 2 bytes        | 3 bytes             | 4 bytes                  |
| ASCII hexadecimal | "8" (38H)                 | "58" (35H 38H) | "058" (30H 35H 38H) | "0058" (30H 30H 35H 38H) |

\*1 Values in '( )' indicate ASCII code.

## ■ Calculation procedure for 16-bit CRC (for MODBUS)

This is an error check method to be used when data are transmitted/received with the RTU mode of the MODBUS protocol. The data length of CRC is fixed to 2 bytes (16 bits), and the CRC is calculated every 1 byte (8 bits) from the start of the calculating range according to the following procedure.

1. Load a 16-bit register whose bits are all '1'.
2. Exclusive OR (XOR) the first 1 byte (8 bits) of the calculating range with 8 bits in above 1.
3. Shift the result of the step 2. for one bit right.
4. If the least significant bit in above 2. is '1', exclusive OR (XOR) the result of 3. with the generator polynomial (A001H). If the least significant bit is '0', shift the result of step 3. one bit right (operation described in 3.) without the exclusive OR (XOR) operation.
5. Repeat steps 3. and 4. for 8 times.
6. Exclusive OR (XOR) the result of the above 5 with the next 1 byte (8 bits).
7. Repeat step 3 through 6 until all bytes have been processed. The final result is CRC value.
8. The CRC value is stored in a packet in the order of lower 8 bits → upper 8 bits.

**Ex.**

The calculation example of 16-bit CRC (for MODBUS)

Packet example:

| Station number | Function code | 16-bit CRC |     |
|----------------|---------------|------------|-----|
| 02H            | 07H           | 41H        | 12H |

Calculation method of 16-bit CRC (for MODBUS) for the above packet example

| CRC error checking procedure                    | 16-bit register (MSB) |           | Flag | Calculating procedure |
|-------------------------------------------------|-----------------------|-----------|------|-----------------------|
| (Load a 16-bit register whose bits are all '1') | 1111 1111             | 1111 1111 | -    | 1 to 2                |
| 02H (Station number)                            | -                     | 0000 0010 |      |                       |

**A**

■Check code calculation range

The following shows specification examples of the check code calculation code.

Example 1: Calculating range when 1 and n-1 are specified as the start and the end respectively.  
Example 2: Calculating range when 2 and n-1 are specified as the start and the end respectively.  
Example 3: Calculating range when 2 and n-2 are specified as the start and the end respectively.

Non-verified reception

The usage example for non-verified reception is shown below.

Using a non-verified reception element has the following advantages in the case of the packet format shown above.

- The only necessary data can be stored in the device memory of a CPU module and buffer memory.
- A single protocol (packet) can handle receive packets that includes data whose contents vary each time.

# Appendix 6 Processing Time

## Processing time for nonprocedural protocol (guideline)

The processing time for the Output and Input instructions can be estimated by the following formula.  
Note, however, that the processing time may become longer depending on other communication functions (e.g., communication using the MC protocol) and special functions (e.g., ASCII-binary conversion, transmission control) that are used at the same time.  
The value obtained from the following formula is considered to be the processing time taken for reception or transmission only when CH1 only is used (RS-232 connection).

### ■OUTPUT instruction

$$Tp = St + (Dle / Cr \times 1000 + 0.07) \times Ds + T1$$

- $Tp^{*1}$  : The time from the start of execution of the Output instruction to the End processing of the sequence scan at the completion of the Output instruction execution (ms)
- $St$  : Scan time
- $Dle$  : Data length of 1 byte at data transmission (number of bits)
- $Cr$  : Communication rate (bps)
- $Ds$  : Number of bytes of send data
- $T1$  : C24  $T1=2.7$

\*1 This stands for the time range of processing ( $Tp$ ).

A

## ■INPUT instruction

$$T_p = S_r + 0.09 \times D_r + T_2$$

- $T_p^{*1}$  : Time from the start of the INPUT instruction execution to the start of End processing for the sequence scan at the completion of the INPUT instruction execution (ms)
- $S_r$  : Scan time
- $D_r$  : Number of bytes of reception data
- $T_2$  : C24  $T_2=6.3$

\*1 This indicates the range of processing time ( $T_p$ ).

\*2 It indicates the time from when C24 receives data from the line to when the 'CH1 reception data read request' (X3) turns ON when only read processing of 30 bytes data is performed with one of the channels on C24 used.

\*3 When DX3 (direct mode) is used, C24 is accessed at the time of the instruction execution with the program. DX3 (direct mode) speeds up reading input compared to X3 (refresh mode). For differences between the modes, refer to the following manual.

📖 MELSEC iQ-R Programmable Controller CPU Module User's Manual

# Appendix 7 When Connecting the Module to a Remote Head Module

This section describes the restrictions and communication example for when connecting the C24 to a remote head module.

## Restrictions

This section describes the restricted functions and specifications of when connecting the C24 to a remote head module.

### When creating a program

- Dedicated instructions cannot be used.
- Data cannot be received with an interrupt program.

### Communication using the MC protocol

The command that can be used differs from that of the CPU module. For the command that can be used in the remote head module, refer to the following.

 MELSEC Communication Protocol Reference Manual

### Communication using the MODBUS slave function

For the restrictions on communications using the MODBUS slave function, refer to the following section.

 Page 115 Specifying an access target

# Communication example

This section describes the communication example for when connecting the C24 to a remote head module.

## System configuration example

| No. | Component                                | Network                  | Protocol                                                                          |

| (4) | External device (temperature controller) | —                        | Predefined protocol                                                               |

## Communication procedure

The following shows the procedure to send/receive data.

### ■Data communication using the predefined protocol

- ① Writes send data to the link register (W) of the CPU module to store the send data in the data storage area set in the packet setting of the predefined protocol support function.
- ② Executes the REMTO instruction to write the number of consecutive protocol executions to the buffer memory of the C24.
- ③ Executes the REMTO instruction to write the number of a protocol to be executed to the buffer memory of the C24.
- ④ Executes the protocol by 'CH2 protocol execution request' (YA).
- ⑤ Checks the protocol execution by 'CH2 protocol execution completion' (XC).
- ⑥ Reads the predefined protocol execution result, result of the execution count, and matched packet number from the buffer memory of the C24 with the REMFR instruction.
- ⑦ Reads the data received from the external device which is transferred from the device of the remote head module to the link register (W) of the CPU module.

A

## ■ Data communication using the nonprocedural or bidirectional protocol

### • Receiving procedure

- ① Checks data received from the external device by 'CH1 reception data read request' (X3).
- ② Transfers the received data from the buffer memory of the C24 to the device of the remote head module by refresh (remote head module ⇔ C24).
- ③ Reads the received data transferred to the link register (W) of the CPU module by link refresh.

### • Sending procedure

- ① Writes send data to the link register (W) of the CPU module to write the send data to the buffer memory of the C24.
- ② Issues the transmission request by 'CH1 transmission request' (Y0).
- ③ 'CH1 transmission normal completion' (X0) turns ON when the execution of the transmission request completes.

## Setting in the master station on CC-Link IE Field Network

Connect the engineering tool to the CPU module of the master station on CC-Link IE Field Network and set parameters.

1. Set the CPU module as follows:

 [Project] ⇒ [New]

2. Click the [Setting Change] button to set to use module labels.

3. Set the CC-Link IE Field Network master/local module as follows.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

A

4. Click the [Setting Change] button to set to use module labels.

5. Set the items in "Required Settings" of "Module Parameter" as follows.

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71GF11-T2] ⇒ [Module Parameter] ⇒ [Required Settings]

| Setting Item                                 |                  |
|----------------------------------------------|------------------|
| Item                                         | Setting          |
| <b>Station Type</b>                          |                  |
| Station Type                                 | Master Station   |
| <b>Network Number</b>                        |                  |
| Network Number                               | 1                |
| <b>Station Number</b>                        |                  |
| Setting Method                               | Parameter Editor |
| Station No.                                  | 0                |
| <b>Parameter Setting Method</b>              |                  |
| Setting Method of Basic/Application Settings | Parameter Editor |

6. Set the network configuration as follows.

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71GF11-T2] ⇒ [Module Parameter] ⇒ [Basic Settings] ⇒ [Network Configuration Settings]

## 7. Set the refresh settings as follows.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71GF11-T2] ⇒ [Module Parameter] ⇒ [Basic Settings]  
⇒ [Refresh Setting]

| No. | Link Side   |        |       |       |                                                                                   | CPU Side                   |             |        |       |       |

| 5   |             |        |       |       |  |                            |             |        |       |       |

## 8. Write the set parameters to the CPU module of the master station on CC-Link IE Field Network. Then, reset the CPU module or power off and on the system.

 [Online] ⇒ [Write to PLC]

### Point

In this example, default values are used for parameters that are not shown above. For the parameters, refer to the following.

 MELSEC iQ-R CC-Link IE Field Network User's Manual (Application)

## Setting in the intelligent device station on CC-Link IE Field Network

Connect the engineering tool to the remote head module of the intelligent device station on CC-Link IE Field Network and set the parameters.

1. Set the remote head module as follows.

 [Project] ⇒ [New]

The 'New' dialog box is shown with the following settings:

- Series: RCPU
- Type: RJ72GF15-T2
- Mode: (empty)
- Program Language: Do not Specify

Buttons: OK, Cancel

2. Set the items in "Network Required Setting" of "CPU Parameter" as follows.

 [Navigation window] ⇒ [Parameter] ⇒ [RJ72GF15-T2] ⇒ [CPU Parameter] ⇒ [Network Required Setting]

| Setting Item          |         |
|-----------------------|---------|
| Item                  | Setting |
| <b>Network Number</b> |         |
| Network Number        | 1       |
| <b>Station Number</b> |         |
| Station No.           | 1       |

3. Set the C24 as follows.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

The 'Add New Module' dialog box is shown with the following settings:

- Module Selection**
  - Module Type: Information Module
  - Module Name: RJ71C24
  - Station Type: (empty)
- Advanced Settings**
  - Mounting Position**
    - Mounting Base: Main Base
    - Mounting Slot No.: 0
    - Start I/O No. Specification: Not Set
    - Start I/O No.: 0000 H
    - Number of Occupied Points per 1 Slot: 32Point
- Module Type**
  - Select module type.

Buttons: OK, Cancel

**4.** Click the [OK] button.

**5.** Set parameters of the C24 according to the protocol to be used.

☞ Page 614 Program example of a predefined protocol

☞ Page 619 Program examples of a nonprocedural protocol or bidirectional protocol

## Program example of a predefined protocol

The following shows a program example to connect an external device (temperature controller) to the CH2 of a C24, and to execute a predefined protocol.

### ■Module parameter setting of a C24

1. Set the items in "Basic Settings" as follows:

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter] ⇒ [Basic Settings]

| Setting Item                                     |                                                    |                     |
|--------------------------------------------------|----------------------------------------------------|---------------------|
| Item                                             | CH1                                                | CH2                 |
| <b>Various control specification</b>             | <b>Set the various control specification.</b>      |                     |
| TEST MODE setting                                | No specification                                   |                     |
| Communication protocol setting                   | MELSDFT connection                                 | Predefined protocol |
| Communication speed setting                      | Automatically set                                  | 9600bps             |
| <b>transmission setting</b>                      | <b>Set the transmission method.</b>                |                     |
| Operation setting                                | Independent                                        | Independent         |
| Data bit                                         | 7                                                  | 7                   |
| Parity bit                                       | None                                               | Yes                 |
| Odd/even parity                                  | Odd                                                | Even                |
| Stop bit                                         | 1                                                  | 2                   |
| Sumcheck code                                    | None                                               | None                |
| Online change                                    | Disable                                            | Disable             |
| Setting change                                   | Disable                                            | Disable             |
| Station Number Settings (CH1, 2 common: 0 to 31) | 0                                                  |                     |
| <b>signal setting</b>                            | <b>Set the ON/OFF status of the RS/DTR signal.</b> |                     |

2. Write the set parameters to the remote head module of the intelligent device station on CC-Link IE Field Network. Then, reset the remote head module or power the system off and on.

 [Online] ⇒ [Write to PLC]

### Point

In this example, default values are used for parameters that are not shown above. For the parameters, refer to the following.

 MELSEC iQ-R CC-Link IE Field Network User's Manual (Application)

 Page 454 PARAMETER SETTING

### ■Predefined protocol support function setting of a C24

1. Select [Tool]⇒[Predefined Protocol Support Function] from an Engineering tool.
2. Select "Serial Communication Module" in "Module Type" in the "Predefined Protocol Support Function" screen.

3. Select [File] ⇒ [New] in the "Predefined Protocol Support Function" screen.

4. Select [Edit] ⇒ [Add Protocol] in the "Protocol Setting" screen.

5. Select "Predefined Protocol Library" in "Type" on the "Add Protocol" screen, and select the protocol to be used in "Protocol to Add".

6. Click the "Variable Unset" cell of "Packet Setting" screen on the "Protocol Setting" screen.

| Protocol No. | Manufacturer | Model | Protocol Name              | Communication Type | -> Send<br><- Receive | Packet Name                  | Packet Setting |
|--------------|--------------|-------|----------------------------|--------------------|-----------------------|------------------------------|----------------|
| 1            | OMRON        | EJ1   | 0601H:RD Controller Status | Send&Receive       | ->                    | 0601H:RD Controller Status   | Variable Unset |
|              |              |       |                            |                    | <-(1)                 | NDR/0601H:RD Controller Sta  | Variable Unset |
|              |              |       |                            |                    | <-(2)                 | ERR/0601H:RD Controller Stal | Variable Unset |
|              |              |       |                            |                    | <-(3)                 | ERR:Command Finished Abnor   | Variable Unset |

7. Click the "Variable unset error" cell on the "Packet Setting" screen

| Element No. | Element Type        | Element Name           | Element Setting                                                                                                |
|-------------|---------------------|------------------------|----------------------------------------------------------------------------------------------------------------|
| 1           | Header              | STX                    | [STX](1Byte)                                                                                                   |
| 2           | Conversion Variable | Communication Unit No. | Variable unset error(->HEX/Fixed Number of Data/Number of data (1)/Digit (2)/Padded (0)/Word/Delimiter (none)) |

8. Enter 'W0' to "Send Data Storage Area" on the "Element Setting" screen.

9. Set the packet settings in the "Variable Unset" cell of "Packet Setting" on the "Protocol Setting" screen with the same procedure (from step 5 to step 8).

Set the following values for the data storage area.

| Packet name                      | Element number | Element name           | Data storage area specification |
|----------------------------------|----------------|------------------------|---------------------------------|
| NOR/0601H:RD Controller Status   | 2              | Communication Unit No. | Set 'W1000'                     |
|                                  | 8              | Operation Status       | Set 'W1001'                     |
|                                  | 9              | Related Information    | Set 'W1002'                     |
| ERR/0601H; RD Controller Status  | 2              | Communication Unit No. | Set 'W1000'                     |
|                                  | 7              | Response Code          | Set 'W1003'                     |
| ERR: Command Finished Abnormally | 2              | Communication Unit No. | Set 'W1000'                     |
|                                  | 4              | End Code               | Set 'W1004'                     |

10. Select [Online]⇒ [Write to Module] from Engineering tool.

11. Select "CPU Built-in Memory" in "Target Memory" on the "Write to Module" screen, and click the [Execute] button.

Target Module Selection

Module Selection: 0000:R371C24

Target Memory: CPU Built-in Memory

Please save in the protocol setting file (\*.pf2) because the data to be written to module does not include the following information.

[Non-written Data in Target Memory]  
Manufacturer  
Packet Name  
Protocol Detailed Setting Type, Version, Explanation  
Packet Setting Configuration Element Name

Execute Cancel

## ■Program example

This program uses the module labels of the CC-Link IE Field Network master/local module. Write the program to the CPU module on the master station.

| Category                                        | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Description                                     | Device                |            |           |       |                       |                 |     |            |    |                     |     |            |     |                          |     |            |     |                       |           |            |      |                        |           |            |      |                        |           |            |      |                                   |     |            |      |                                    |     |            |      |                                 |     |            |      |                                    |     |            |      |                      |     |            |      |               |     |            |       |                                  |     |            |       |                                                 |     |            |       |                                |     |            |       |                      |                                     |            |    |                                |                                     |            |    |                               |                                           |            |    |                  |                                     |            |      |                       |                                     |            |      |                 |                                           |            |      |                |                                           |            |      |                           |                                     |            |    |                              |                                     |            |    |

(6) Sets send data and writes the number of consecutive protocol executions and the number of a protocol to be executed to the buffer memory of the C24 with the REMTO instruction.

(62) Issues the predefined protocol execution request when the REMTO instruction completes.

(70) Reads the execution result from the buffer memory of the C24 with the REMFR instruction when the execution of the predefined protocol completes.

# Program examples of a nonprocedural protocol or bidirectional protocol

The following shows program examples to connect an external device (personal computer) to the CH1 of a C24, and to send/receive data by using a nonprocedural protocol or bidirectional protocol with input/output signals.

## Module parameter setting of a C24

1. Set the items in "Basic Settings" as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter] ⇒ [Basic Settings]  
For communication using the bidirectional protocol, set the communication protocol setting to "Bidirectional protocol."

3. Write the set parameters to the remote head module of the intelligent device station on CC-Link IE Field Network. Then, reset the remote head module or power the system off and on.

[Online] ⇒ [Write to PLC]

### Point

In this example, default values are used for parameters that are not shown above. For the parameters, refer to the following.

MELSEC iQ-R CC-Link IE Field Network User's Manual (Application)

Page 454 PARAMETER SETTING

## ■Program example for data reception

This program uses the module labels of the CC-Link IE Field Network master/local module. Write the program to the CPU module on the master station.

| Category                             | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Description                                     | Device       |                       |       |                       |                 |     |     |              |    |                   |     |     |              |     |                              |     |     |              |      |                             |     |     |              |      |                            |     |     |              |       |                                     |     |     |              |       |                                      |     |     |              |       |                   |                                     |     |              |       |              |                                           |     |              |       |                  |                                     |     |              |       |            |                                     |     |              |    |       |                                           |     |              |    |         |                                     |     |              |      |  |  |  |

(6) Reads the received data when the C24 receives data normally.

(18) Reads error description (error code) when the C24 detects an error at data reception. (Unnecessary for bidirectional protocols.)

## ■Program for data transmission

This program uses the module labels of the CC-Link IE Field Network master/local module. Write the program to the CPU module on the master station.

| Category                              | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                                     | Device       |                       |       |                       |                 |     |     |              |    |                        |     |     |              |     |                                   |     |     |              |      |                              |     |     |              |      |                              |     |     |              |       |                                       |     |     |              |       |                                  |     |     |              |       |                           |     |     |              |       |                |                                     |     |              |    |           |                                           |     |              |    |                         |                                     |     |              |       |            |                                     |     |              |    |       |                                           |     |              |    |         |                                     |     |              |     |  |  |  |

| wResult                               | Word [Unsigned]/Bit String [16-bit]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | ...                                             | VAR_GLOBAL ▾ | D20                   |       |                       |                 |     |     |              |    |                        |     |     |              |     |                                   |     |     |              |      |                              |     |     |              |      |                              |     |     |              |       |                                       |     |     |              |       |                                  |     |     |              |       |                           |     |     |              |       |                |                                     |     |              |    |           |                                           |     |              |    |                         |                                     |     |              |       |            |                                     |     |              |    |       |                                           |     |              |    |         |                                     |     |              |     |  |  |  |

(6) Sets send data and issues a send request.

(32) Performs the processing when the transmission processing completes normally.

(35) Performs the processing when the transmission processing completes abnormally.

# Appendix 8 Using MODBUS in a Redundant System

This section explains the restrictions and communication examples when using MODBUS in a redundant system. For the restrictions when using a C24 in a redundant system with a redundant extension base unit, refer to the following section.

 Page 661 Using the Module in the Redundant System with Redundant Extension Base Unit

## Restrictions

### Available modules

Use the following modules in a redundant system.

| Model      | Type                        | Firmware version |
|------------|-----------------------------|------------------|
| RnPCPU     | Process CPU                 | '24' or later    |
| R6RFM      | Redundant function module   | '01' or later    |
| RJ71C24    | Serial communication module | '13' or later    |
| RJ71C24-R2 |                             |                  |
| RJ71C24-R4 |                             |                  |

### Available functions

The following table shows the availability of each function when using a C24 in a redundant system.

○: Available, —: Not available

| Function               |                                        | Availability in a redundant system |
|------------------------|----------------------------------------|------------------------------------|
| MODBUS master function | Communication with predefined protocol | ○                                  |
|                        | Simple CPU communication function      | —                                  |
| MODBUS slave function  |                                        | ○                                  |

### Communication using a dedicated instruction

If the system is switched during dedicated instruction execution, the instruction may not be completed. Execute it again from the control system CPU module after system switching.

## Redundant master station (single line)

Connect the master station of the control system and that of the standby system with a tracking cable.

If an error occurs in the master station of the control system, the master station of the standby system performs control and continues communications with a slave station.

- (1) Tracking cable
- (2) Master station (control system)
- (3) Master station (standby system)
- (4) MODBUS slave device

## System switching

An execution result of the protocols registered for the predefined protocol support function (GP.CPRTCL) is monitored. When an error occurs, the system switching instruction (SP.CONTSW) is executed in the process CPU (redundant mode) of the control system.<sup>\*1</sup>

<sup>\*1</sup> To execute this instruction, 'System switching by a user' (SM1646) must be turned ON (manual switching permitted) in advance.

## Cases in which the system can be switched

The system is switched if any of the following errors occurs:

- Cable disconnection
- Communication error
- Power interruption

A

## Redundant master station (redundant line)

Connect the master station of the control system and that of the standby system with a tracking cable.

Set a slave station for each master station.

If an error occurs in the master station of the control system, the master station of the standby system performs control and continues communications with slave stations.

- (1) Tracking cable
- (2) Master station (control system)
- (3) Master station (standby system)
- (4) MODBUS slave device

### Precautions

- The configurations of the control system and the standby system must be the same.
- When using RS-232, only one MODBUS slave device can be connected.

### System switching

An execution result of the protocols registered for the predefined protocol support function (GP.CPRTCL) is monitored.

When an error occurs, the system switching instruction (SP.CONTSW) is executed in the process CPU (redundant mode) of the control system.\*1

\*1 To execute this instruction, 'System switching by a user' (SM1646) must be turned ON (manual switching permitted) in advance.

### Cases in which the system can be switched

The system is switched if any of the following errors occurs:

- Cable disconnection
- Communication error
- Power interruption

## Redundant slave station (redundant line)

Connect the slave station of the control system and that of the standby system with a tracking cable.

Prepare a line to the master station for each of the slave stations of the control system and the standby system.

If an error occurs in the slave station of the control system, the slave station of the standby system performs control and continues communications with the master station.

- (1) MODBUS master device
- (2) Slave station (control system)
- (3) Slave station (standby system)
- (4) Tracking cable

## System switching

Data for alive check is periodically sent from the master station to determine whether a communication error occurs, and the data is monitored in slave stations.

When an error occurs, the system switching instruction (SP.CONTSW) is executed in the process CPU (redundant mode) of the control system.\*<sup>1</sup>

The master station determines which slave station is currently operating as the control system by reading the values in 'Control system judgment flag' (SM1634) and 'Standby system judgment flag' (SM1635) of each slave station.

\*<sup>1</sup> To execute this instruction, 'System switching by a user' (SM1646) must be turned ON (manual switching permitted) in advance.

## Cases in which the system can be switched

The system is switched if any of the following errors occurs:

- Cable disconnection
- Communication error
- Power interruption

# Communication examples for a redundant master station (single line)

The following shows program examples to continue communications with a slave station by switching the master station of the standby system to the control system if an error occurs in the master station of the control system.

Point

Common sample programs can be used for redundant master stations (both single line and redundant line). Therefore, a redundant master station (single line) is used for explanation in communication examples shown below.

A program executed in a master station (standby system) is required for a redundant master station (single line). For details on this type of program, refer to the following section.

( Page 639 Considerations for a redundant master station (single line))

## Overview

The following shows the operation overviews of a sample program used for a communication example.

### Normal operation

- (1) Master station (control system): RJ71C24 (predefined protocol)  
(2) Master station (standby system): RJ71C24 (predefined protocol)  
(3) Slave station: RJ71C24 (MODBUS slave (RTU))

| No. | Description                                                                                                                                                                                                                                                                    |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ①   | The master station (control system) sends the following request message to the slave station with the GP.CPRTCL instruction. <ul style="list-style-type: none"><li>Read holding registers (FC: 03)<br/>(request to read a value in the read holding register 400001)</li></ul> |
| ②   | The slave station returns a value in D0 according to the MODBUS device assignment parameter settings.<br>The master station (control system) stores received data in W5 according to protocol setting data.                                                                    |

The above operations are repeated every three seconds.

## ■When an error occurs

- (1) Master station (control system): RJ71C24 (predefined protocol)  
 (2) Master station (standby system): RJ71C24 (predefined protocol)  
 (3) Slave station: RJ71C24 (MODBUS slave (RTU))

| No. | Description                                                                                                                                                                                                                                        |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ①   | The master station (control system) sends a request message to the slave station with the GP.CPRTCL instruction.                                                                                                                                   |
| ②   | If the GP.CPRTCL instruction completes with an error, the master station (control system) switches the system with the SP.CONTSW instruction.                                                                                                      |
| ③   | The master station (standby system) that has switched to the new control system sends a request message to the slave station with the GP.CPRTCL instruction in the same way as the master station (control system) that is the old control system. |
| ④   | The slave station sends a response message to the master station (standby system) that has switched to the new control system.                                                                                                                     |

System configuration

- (1) Tracking cable
- (2) Master station (control system): RJ71C24 (predefined protocol)
- (3) Master station (standby system): RJ71C24 (predefined protocol)
- (4) Slave station: RJ71C24 (MODBUS slave (RTU))

| Type           | Model   | Type                        | Start I/O No. |
|----------------|---------|-----------------------------|---------------|
| Master station | RnPCPU  | Process CPU                 | 3E00H         |
|                | R6RFM   | Redundant function module   | 0000H         |
|                | RJ71C24 | Serial communication module | 0020H         |
| Slave station  | RCPU    | CPU module                  | 3E00H         |
|                | RJ71C24 | Serial communication module | 0000H         |

Setting for a master station (control system)

The following shows the procedure for connecting to the CPU module on a master station and setting parameters in an engineering tool.

1. Set the CPU module as follows:

[Project] ⇨ [New]

2. Click the [Setting Change] button to set to use module labels.
3. Click the [OK] button to add module labels of the CPU module.

4. Set the R6RFM as follows:

[Navigation window] ⇒ [Parameter] ⇒ [System Parameter] ⇒ [I/O Assignment] tab ⇒ [I/O Assignment Setting]

Add New Module

Module Selection

Module Type CPU Extension

Module Name R6RFM

Station Type

Advanced Settings

Mounting Position

Mounting Base Main Base

Mounting Slot No. 0

Start I/O No. Specification Not Set

Start I/O No. 0000 H

Number of Occupied Points per 1 Slot 32 Points

Module Selection

Select the module to be added.

OK Cancel

5. Set the RJ71C24 as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

Add New Module

Module Selection

Module Type Information Module

Module Name RJ71C24

Station Type

Advanced Settings

Mounting Position

Mounting Base Main Base

Mounting Slot No. 1

Start I/O No. Specification Not Set

Start I/O No. 0020 H

Number of Occupied Points per 1 Slot 32Point

Module Selection

Select the module to be added.

OK Cancel

6. Click the [OK] button to add module labels of the RJ71C24.

MELSOFT GX Works3

Add a module.

[Module Name] RJ71C24

[Start I/O No.] 0020

Module Setting

**7.** Set the RS-485 (CH2) of the master station as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter] ⇒ [Basic Settings] ⇒ [Various control specification]

| Item                          |                                         | Description        |                     |
|-------------------------------|-----------------------------------------|--------------------|---------------------|
| Various control specification | Communication protocol setting          |                    | Predefined protocol |
|                               | Communication speed setting             |                    | 230400 bps          |
|                               | Transmission setting                    | Operation setting  | Independent         |
|                               |                                         | Data bit           | 8                   |
|                               |                                         | Parity bit         | None                |
|                               |                                         | Odd/even parity    | —                   |
|                               |                                         | Stop bit           | 1                   |
|                               |                                         | Sum check code     | None                |
|                               |                                         | Online change      | Enable              |
|                               |                                         | Setting change     | Disable             |
|                               | Station number setting                  |                    | 0                   |
|                               | MODBUS station number setting           |                    | —                   |
| Communication control setting | Echo back enable/prohibit specification | Echo back prohibit |                     |

**8.** Write the set parameters to the CPU module that controls the master station.

[Online] ⇒ [Write to PLC]

**9.** Select [Tool] ⇒ [Predefined Protocol Support Function] in an engineering tool.

**10.** Select "Module Type" ⇒ "Serial Communication Module."

**11.** Select [File] ⇒ [New].

**12.** Select [Edit] ⇒ [Add Protocol].

**13.** Select "Predefined Protocol Library" for "Type," and select a protocol to be used in "Protocol to Add."

The "Add Protocol" dialog box is shown. It has a title bar "Add Protocol" with a close button. Inside, it says "Adds new protocol." Below that is "Selection of Protocol Type to Add". There is a "Type:" label followed by a dropdown menu set to "Predefined Protocol Library" and a "Reference" button. A note says: "\* Select from Predefined Protocol Library. Please select manufacturer, model and protocol name from Protocol to Add." Below this is "Protocol to Add" with a table:

| Protocol No. | Manufacturer       | Model  | Protocol Name           |
|--------------|--------------------|--------|-------------------------|
| 1            | Schneider Electric | MODBUS | 03:RD Holding Registers |

At the bottom are "OK" and "Cancel" buttons.

| Protocol No. | Manufacturer       | Model  | Protocol name            |
|--------------|--------------------|--------|--------------------------|
| 1            | Schneider Electric | MODBUS | 03: RD Holding Registers |

**14.** Right-click the added protocol, and select [Protocol Detailed Setting] from the shortcut menu.

The screenshot shows the MELSOFT Series software interface. The title bar is "MELSOFT Series <Predefined Protocol Support Function-Serial Communication Module> - [Protocol Setting - Untitled]". The menu bar includes File, Edit, Online, Tool, Debugging Support Function, and Window. Below the menu bar is a toolbar. The main area is a table with columns: Protocol No., Manufacturer, Model, Protocol Name, Communication Type, Send/Receive, Packet Name, and Packet Setting. The first row is highlighted with Protocol No. 1, Manufacturer Schneider Electric, Model MODBUS, Protocol Name 03:RD Holding Registers, and Communication Type Send&Receive. A right-click context menu is open over the first row, showing options: Add Protocol..., Change to Editable Protocol, and Protocol Detailed Setting... (which is highlighted). At the bottom left is an "Add" button.

**15.** Set '30' for "Receive Wait Time."

The "Protocol Detailed Setting" dialog box is shown. It has a title bar "Protocol Detailed Setting" with a close button. It is divided into several sections:

- Connected Device Information:** Manufacturer (Schneider Electric), Type (Communication Protocol), Model (MODBUS), Version (0001), Explanation (MODBUS).
- Protocol Setting Information:** Protocol No. (1), Protocol Name (03:RD Holding Registers), Communication Type (Send&Receive).
- Receive Setting:** Clear OS area (receive data area) before protocol execution (Enable/Disable). **Receive Wait Time** is set to 30 x 100ms. [Setting Range] 0 to 30000 (0: Infinite Wait).
- Send Setting:** Number of Send Retries (0) Times [Setting Range] 0 to 10. Send Retry Interval (500) x 10ms [Setting Range] 0 to 30000. Standby Time (0) x 10ms [Setting Range] 0 to 30000. Monitoring Time (200) x 100ms [Setting Range] 0 to 3000 (0: Infinite Wait).

At the bottom is a "Communication Parameter Batch Setting" button and "OK" and "Cancel" buttons.

A

**16.** Right-click the added protocol, and select [Device Batch Setting] from the shortcut menu.

**17.** Set 'W0' for "Device No."

**18.** Write the set protocol setting data to the module.

 [Online] ⇒ [Write to Module]

**19.** Reset the CPU module or turn the power OFF and ON.

## Precautions

- If '0' is set for "Receive Wait Time," the system is not switched because it continues waiting for a response from a slave station.
- If the CPU module is in the backup mode, protocol setting data cannot be written. Be sure to switch the CPU module to the separate mode before writing.
- Protocol setting data cannot be written to both systems at the same time. Write it to the control system and the standby system individually.
- The target memory in which protocol setting data is written must be the same for the control system and the standby system.

## Setting for a master station (standby system)

Set a master station (standby system) with the same procedure as a master station (control system).

 Page 630 Setting for a master station (control system)

## Setting for a slave station

The following shows the procedure for connecting to the CPU module on a slave station and setting parameters in an engineering tool.

1. Set the CPU module as follows:

 [Project] ⇒ [New]

2. Click the [Setting Change] button to set to use module labels.
3. Click the [OK] button to add module labels of the CPU module.

4. Set the RJ71C24 as follows:

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

A

5. Click the [OK] button to add module labels of the RJ71C24.

6. Set the RS-485 (CH2) of the slave station as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter] ⇒ [Basic Settings] ⇒ [Various control specification]

| Item                          | Description                               |                               |
|-------------------------------|-------------------------------------------|-------------------------------|
| Various control specification | Communication protocol setting            | MODBUS slave (RTU)            |
|                               | Communication speed setting <sup>*1</sup> | 230400 bps                    |
|                               | Transmission setting                      | Operation setting             |
|                               |                                           | Data bit <sup>*1</sup>        |
|                               |                                           | Parity bit <sup>*1</sup>      |
|                               |                                           | Odd/even parity <sup>*1</sup> |
|                               |                                           | Stop bit <sup>*1</sup>        |
|                               |                                           | Sum check code <sup>*1</sup>  |
|                               |                                           | Online change                 |
|                               |                                           | Setting change                |
|                               | Station number setting                    | 0                             |
|                               | MODBUS station number setting             | 1                             |

<sup>\*1</sup> Set the same value as the master station.

7. Write the set parameters to the CPU module on the slave station.

[Online] ⇒ [Write to PLC]

8. Reset the CPU module or turn the power OFF and ON.

## Program example for a master station

<sup>\*1</sup> Do not specify it as a target for tracking transfer. (MELSEC iQ-R Process CPU Module User's Manual)

For information on the module FB to be used, refer to the following manual.

 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Turns SM1646 ON to execute the SP.CONTSW instruction.
- (2) Sets a value to the device assigned in the protocol setting.
- Sets '1' for the request destination slave station number.
  - Sets the start holding register number and the number of read points so that MODBUS device (400001) will be read.
- Sets a value for the input label of M+RJ71C24\_ExecCommonProtocol.
- Sets '2' for the communication channel.
  - Sets '1' for the number of consecutive protocol executions.
  - Sets '1' for the execution protocol number specification.
- Turns M+RJ71C24\_ExecCommonProtocol execution request ON.
- (18) Executes M+RJ71C24\_ExecCommonProtocol.
- (74) Turns the SP.CONTSW instruction execution request ON if an error occurs in completion.
- (76) Starts the timer for next sending after completion of M+RJ71C24\_ExecCommonProtocol.
- (80) Measures for three seconds.
- (85) Turns the next transmission request execution request ON after three seconds.
- (88) Switches the system with the SP.CONTSW instruction if an error occurs in completion.

## Program example for a slave station

Create a program for a slave station as necessary.

## Considerations for a redundant master station (single line)

For a redundant master station (single line), a master station (standby system) also receives data sent by a master station (control system) and a slave station. This causes a buffer full error (7F6AH) in the master station (standby system). If a buffer full error occurs, the buffer area is cleared when the master station (standby system) switches to the new control system; therefore, the new control system operates normally after system switching.

To avoid a buffer full error in a master station (standby system), a functional protocol 'receive data clear (protocol No.201)' of the predefined protocol function must be periodically executed in the master station (standby system).

In addition, add a sample program executed in the master station (standby system) and correct a sample program executed in the master station (control system).

### Precautions

- Execute a program in both systems.

For details, refer to the following:

( MELSEC iQ-R Process CPU Module User's Manual)

- Do not specify a device assigned to a module label or global label in a sample program as a target for tracking transfer.

For details on tracking transfer, refer to the following:

( MELSEC iQ-R Process CPU Module User's Manual)

### ■Example of a program added for a master station (standby system)

| Category            | Label name |            |      |   |                |                                     |     |            |    |    |                          |                                     |     |            |    |    |                                            |                                          |     |            |    |    |                         |                                     |     |            |     |    |                              |                                          |     |            |     |    |                         |                                     |     |            |      |    |                                       |                                     |     |            |    |    |                                       |                                     |     |            |    |    |                                   |                                     |     |            |    |    |                                        |       |     |            |    |    |                           |     |     |            |      |    |                                |     |     |            |      |    |                          |     |     |            |      |    |                                |          |     |            |      |    |                         |                                           |     |            |      |    |                                      |       |     |            |     |  |  |

\*1 Add and define global labels as shown in the red frame.

■Example of a program corrected for a master station (control system)

Correct the program shown in the following section.

📖 Page 636 Program example for a master station

- Part to be corrected

Add a close contact (M302) in the red frame.

# Communication examples for a redundant slave station (redundant line)

The following shows program examples to continue communications with the master station by switching a slave station (standby system) to the control system if an error occurs in a slave station (control system).

## Overview

The following shows the operation overviews of a sample program used for a communication example.

### ■Normal operation

(1) Master station 1 and master station 2: RJ71C24-R2 (predefined protocol)

(2) Slave station (control system): RJ71C24 (MODBUS slave (RTU))

(3) Slave station (standby system): RJ71C24 (MODBUS slave (RTU))

| No. | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ①   | The master station sends the following request messages to the slave stations (control system and standby system) with the GP.CPRTCL instruction. <ul style="list-style-type: none"> <li>Reading two points from the coil 022115 with 'Read coils (FC:01)' (reading SM1634 and SM1635 used to determine the control system)</li> <li>Writing a value for alive check to the holding register 412288 with 'Write multiple registers (FC:16)'</li> </ul> |
| ②   | Each of the slave stations (control system and standby system) processes the request from the master station according to the MODBUS assignment parameter and sends a response message.                                                                                                                                                                                                                                                                |
| ③   | The master station determines the value acquired with 'Read coils' and sends a request message used for actual control to the slave station (control system).                                                                                                                                                                                                                                                                                          |
| ④   | The slave station (control system) processes the request from the master station according to the MODBUS assignment parameter, and sends a response message.                                                                                                                                                                                                                                                                                           |

The above operations are repeated every three seconds.

# ■When an error occurs

- (1) Master station 1 and master station 2: RJ71C24-R2 (predefined protocol)  
 (2) Slave station (control system): RJ71C24 (MODBUS slave (RTU))  
 (3) Slave station (standby system): RJ71C24 (MODBUS slave (RTU))

| No. | Description                                                                                                                                                                                               |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ①   | The master station sends a request message to each of the slave stations (control system and standby system) with the GP.CPRTCL instruction.                                                              |
| ②   | The slave station (control system) cannot receive the request message, and only the slave station (standby system) sends a response message (data for alive check).                                       |
| ③   | The slave station (control system) switches the system with the SP.CONTSW instruction because data for alive check was not updated after 10 seconds.                                                      |
| ④   | The master station determines the value acquired with 'Read coils' and sends a request message used for actual control to the slave station (standby system) that has switched to the new control system. |
| ⑤   | The slave station (standby system) that has switched to the new control system processes the request from the master station according to the MODBUS assignment parameter, and sends a response message.  |

A

System configuration

- (1) Master station 1 and master station 2: RJ71C24-R2 (predefined protocol)
- (2) Slave station (control system): RJ71C24 (MODBUS slave (RTU))
- (3) Slave station (standby system): RJ71C24 (MODBUS slave (RTU))
- (4) Tracking cable

| Type           | Model        | Type                        | Start I/O No. |
|----------------|--------------|-----------------------------|---------------|
| Master station | RCPU         | CPU module                  | 3E00H         |
|                | RJ71C24-R2*1 | Serial communication module | 0000H         |
|                | RJ71C24-R2*2 |                             | 0020H         |

|                | RJ71C24      | Serial communication module | 0020H         |

\*1 Master station 1  
\*2 Master station 2

Setting for a master station

The following shows the procedure for connecting to the CPU module on a master station and setting parameters in an engineering tool.

1. Set the CPU module as follows:

[Project] ⇒ [New]

2. Click the [Setting Change] button to set to use module labels.

3. Click the [OK] button to add module labels of the CPU module.

4. Set the RJ71C24-R2 (master station 1) as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

5. Click the [OK] button to add module labels of the RJ71C24-R2 (master station 1).

Set the RJ71C24-R2 (master station 2) with the same procedure.

**6.** Set the RS-232 (CH1) of master station 1 and master station 2 as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24-R2] ⇒ [Module Parameter] ⇒ [Basic Settings]  
⇒ [Various control specification]

| Item                          |                                | Description          |                     |
|-------------------------------|--------------------------------|----------------------|---------------------|
| Various control specification | Communication protocol setting |                      | Predefined protocol |
|                               | Communication speed setting    |                      | 230400 bps          |

|                               |                                | Parity bit           | None                |
|                               |                                | Odd/even parity      | —                   |
|                               |                                | Stop bit             | 1                   |
|                               |                                | Sum check code       | None                |
|                               |                                | Online change        | Enable              |
|                               |                                | Setting change       | Disable             |
|                               | Station number setting         |                      | 0                   |
|                               | MODBUS station number setting  |                      | —                   |
|                               | Transmission control setting   | Transmission control | DC code control     |
|                               |                                | DC1/DC3 control      | Control disabled    |
|                               |                                | DC2/DC4 control      | Control disabled    |

**7.** Write the set parameters to the CPU module that controls the master stations.

[Online] ⇒ [Write to PLC]

**8.** Select [Tool] ⇒ [Predefined Protocol Support Function] in an engineering tool.

**9.** Select "Module Type" ⇒ "Serial Communication Module."

**10.** Select [File] ⇒ [New].

**11.** Select [Edit] ⇒ [Add Protocol].

**12.** Select "Predefined Protocol Library" for "Type," and select a protocol to be used in "Protocol to Add."

The "Add Protocol" dialog box is shown. It has a title bar "Add Protocol" with a close button. Inside, it says "Adds new protocol." Below that is "Selection of Protocol Type to Add" with a dropdown menu set to "Predefined Protocol Library" and a "Reference" button. A note says: "\* Select from Predefined Protocol Library. Please select manufacturer, model and protocol name from Protocol to Add." Below this is "Protocol to Add" with a table:

| Protocol No. | Manufacturer       | Model  | Protocol Name |
|--------------|--------------------|--------|---------------|
| 1            | Schneider Electric | MODBUS | 01:RD Coils   |

At the bottom are "OK" and "Cancel" buttons.

| Protocol No. | Manufacturer       | Model  | Protocol name            | Purpose                             |
|--------------|--------------------|--------|--------------------------|-------------------------------------|
| 1            | Schneider Electric | MODBUS | 01: RD Coils             | Determination of the control system |
| 2            |                    |        | 16: WR Multi Register    | Alive check                         |
| 3            |                    |        | 03: RD Holding Registers | Request data for control            |

**13.** Right-click the added protocol, and select [Protocol Detailed Setting] from the shortcut menu.

The screenshot shows the MELSOFT software interface. A table lists three protocols. Protocol 1 is selected, and a right-click context menu is open, showing options like "Add Protocol...", "Change to Editable Protocol", "Protocol Detailed Setting...", "Add Receive Packet", "Delete", "Copy", "Paste", "Delete Multiple Protocols...", and "Copy Multiple Protocols...". The "Protocol Detailed Setting..." option is highlighted.

| Protocol No. | Manufacturer       | Model  | Protocol Name           | Communication Type | Packet Name             | Packet Setting |
|--------------|--------------------|--------|-------------------------|--------------------|-------------------------|----------------|
| 1            | Schneider Electric | MODBUS | 01:RD Coils             | Send&Receive       | 01:RD Coils             | Variable Unset |
| 2            | Schneider El       |        | 16:WR Multi Register    | Send&Receive       | 16:WR Multi Register    | Variable Unset |
| 3            | Schneider El       |        | 03:RD Holding Registers | Send&Receive       | 03:RD Holding Registers | Variable Unset |

**14.** Set '10' for "Receive Wait Time."

Set the same item for protocol number 1 to 3.

The "Protocol Detailed Setting" dialog box is shown. It has tabs for "Connected Device Information", "Protocol Setting Information", "Receive Setting", and "Send Setting". The "Receive Setting" tab is active. It shows "Receive Wait Time" set to 10 x 100ms. The "Send Setting" tab shows "Number of Send Retries" set to 0, "Send Retry Interval" set to 500 x 10ms, "Standby Time" set to 0 x 10ms, and "Monitoring Time" set to 200 x 100ms. At the bottom are "OK" and "Cancel" buttons.

| Connected Device Information                                                                                                             | Protocol Setting Information                                                      | Receive Setting                                                             | Send Setting                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**16.** Write the set protocol setting data to the module.

 [Online] ⇒ [Write to Module]

**17.** Reset the CPU module or turn the power OFF and ON.

## Setting for a slave station (control system)

The following shows the procedure for connecting to the CPU module on a slave station and setting parameters in an engineering tool.

1. Set the CPU module as follows:

 [Project] ⇒ [New]

2. Click the [Setting Change] button to set to use module labels.  
3. Click the [OK] button to add module labels of the CPU module.

4. Set the R6RFM as follows:

 [Navigation window] ⇒ [Parameter] ⇒ [System Parameter] ⇒ [I/O Assignment] tab ⇒ [I/O Assignment Setting]

5. Set the RJ71C24 as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ right-click ⇒ [Add New Module]

6. Click the [OK] button to add module labels of the RJ71C24.

7. Set the RS-232 (CH1) of each of the slave stations (control system and standby system) as follows:

[Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter] ⇒ [Basic Settings] ⇒ [Various control specification]

| Item                          |                                           |                               | Description                |
|-------------------------------|-------------------------------------------|-------------------------------|----------------------------|
| Various control specification | Communication protocol setting            |                               | MODBUS slave station (RTU) |
|                               | Communication speed setting <sup>*1</sup> |                               | 230400 bps                 |

| MODBUS station number setting |                                           | 1                             |                            |

<sup>\*1</sup> Set the same value as the master station.

8. Write the set parameters to the CPU module on the slave station.

[Online] ⇒ [Write to PLC]

9. Reset the CPU module or turn the power OFF and ON.

## Setting for a slave station (standby system)

Set a slave station (standby system) with the same procedure as a slave station (control system).

 Page 649 Setting for a slave station (control system)

## Program examples for master stations

Create a sample program for a master station so that it behaves in the following order:

- Program for master station 1 → program for master station 2 → program for communication to a slave station of the control system

### ■ Master station 1

The following shows a program to control an RJ71C24-R2 the start I/O number of which is 0H.

The control system can be determined and data for alive check can be updated.

| Category            | Label name/FB name For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Sets an initial value for data for alive check.
- (3) Waits for a slave station to start (500 ms).
- (9) Reads special relays (SM1634 and SM1635), sends data for alive check, and performs communication with a slave station every three seconds.
- (15) Reads special relays (SM1634 and SM1635) and turns a send execution trigger for data for alive check ON.
- (18) Sets predefined protocol data to read special relays (SM1634 and SM1635).
- Sets '1' for the request destination slave station number.
  - Sets the start coil number and the number of read points so that MODBUS devices (022115 and 022116) will be read.
- (29) Sets predefined protocol data to send data for alive check.
- Sets '1' for the request destination slave station number.
  - Sets the start register number, the number of write points, and the write size so that MODBUS device (412288) will be written.
  - Sets data for alive check as writing data.
- (41) Sets a value for the input label of M+RJ71C24\_ExeCommonProtocol.
- Sets '2' for the number of consecutive protocol executions.
  - Sets '1' and '2' for the execution protocol number specification.
- (52) Executes M+RJ71C24\_ExeCommonProtocol.
- (111) Updates data for alive check after completion of M+RJ71C24\_ExeCommonProtocol.
- Performs communication with a slave station if the control system is connected. ( Page 658 Communication to a slave station of the control system)

## ■Master station 2

The following shows a program to control an RJ71C24-R2 the start I/O number of which is 20H.

The control system can be determined and data for alive check can be updated.

| Category            | Label name/FB name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Description                                      | Device     |                       |            |           |       | For information on the module FB to be used, refer to the following manual.

📖 MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Sets an initial value for data for alive check.
- (3) Waits for a slave station to start (500 ms).
- (9) Reads special relays (SM1634 and SM1635), sends data for alive check, and performs communication with a slave station every three seconds.
- (15) Reads special relays (SM1634 and SM1635) and turns a send execution trigger for data for alive check ON.
- (18) Sets predefined protocol data to read special relays (SM1634 and SM1635).
  - Sets '1' for the request destination slave station number.
  - Sets the coil number and the number of read points so that MODBUS devices (022115 and 022116) will be read.
- (29) Sets predefined protocol data to send data for alive check.
  - Sets '1' for the request destination slave station number.
  - Sets the start register number, the number of write points, and the write size so that MODBUS device (412288) will be written.
  - Sets data for alive check as writing data.
- (41) Sets a value for the input label of M+RJ71C24\_ExecCommonProtocol.
  - Sets '2' for the number of consecutive protocol executions.
  - Sets '1' and '2' for the execution protocol number specification.
- (52) Executes M+RJ71C24\_ExecCommonProtocol.
- (111) Updates data for alive check after completion of M+RJ71C24\_ExecCommonProtocol.
  - Performs communication with a slave station if the control system is connected. (Page 658 Communication to a slave station of the control system)

## ■Communication to a slave station of the control system

Communication is performed in a master station connected to a slave station of the control system.

For information on the module FB to be used, refer to the following manual.

📖MELSEC iQ-R Serial Communication Module Function Block Reference

- (0) Sets protocol data for communication to a slave station.
- Sets '1' for the request destination slave station number.
  - Sets the start register number and the number of read points so that MODBUS device (400001) will be read.
- Sets a value for the input label of M+RJ71C24\_ExeCommonProtocol.
- Sets '1' for the number of consecutive protocol executions.
  - Sets '3' for the execution protocol number specification.
- (16) Performs communication in master station 1.
- (79) Performs communication in master station 2.
- (142) Performs processing after communication is completed.

A

## Program example for a slave station

The control system can be determined and data for alive check can be updated.

| Category     | Label name                                                                     | Description                                                               | Device |
|--------------|--------------------------------------------------------------------------------|---------------------------------------------------------------------------|--------|
| Module label | RCPU.stSM.bAlways_ON                                                           | Always ON                                                                 | SM400  |
|              | RCPU.stSM.bUser_System_Switching_Availability                                  | System switching by a user                                                | SM1646 |
|              | RCPU.stSM.bControl_System_Identification_Flag                                  | Control system judgment flag                                              | SM1634 |
|              | RCPU.stSM.bStandby_System_Identification_Flag                                  | Standby system judgment flag                                              | SM1635 |
|              | RCPU.stSM.bAfter_System_Switching_One_SCAN_ON_Standby_System_To_Control_System | ON for one scan after system switching (Standby system to control system) | SM1643 |

Label to be defined

|   | Label Name                             | Data Type                           | Class      | Assign (Device/Label) |
|---|----------------------------------------|-------------------------------------|------------|-----------------------|
| 1 | tAliveCheckMonitoringTimer             | Timer                               | VAR_GLOBAL | T0                    |
| 2 | bFirstDataRecvFlag                     | Bit                                 | VAR_GLOBAL | M0                    |
| 3 | bSystemSwitchingAbnormalCompleteDevice | Bit                                 | VAR_GLOBAL | M1                    |
| 4 | wAliveCheckData_PreviousValue          | Word [Unsigned]/Bit String [16-bit] | VAR_GLOBAL | D12286                |
| 5 | wAliveCheckData_RecvData               | Word [Unsigned]/Bit String [16-bit] | VAR_GLOBAL | D12287                |

- (1) Turns SM1646 ON to execute the SP.CONTSW instruction.
- (2) Turns M0 ON to enable system switching after receiving the first data for alive check from the master station.
- (7) Monitors whether data for alive check can be received from the master station (for 10 seconds).
- (24) Switches the system if no data can be received for 10 seconds.
- (33) Resets the monitoring timer if the system is switched by a cause other than a MODBUS communication error.

# Appendix 9 Using the Module in the Redundant System with Redundant Extension Base Unit

This section explains examples when using a C24 in a redundant system with a redundant extension base unit.

## Restrictions

The following shows the restricted functions and specifications of when using a C24 in a redundant system with a redundant extension base unit.

### Available modules

Use the following modules in a redundant system.

| Model      | Type                        | Firmware version |
|------------|-----------------------------|------------------|
| RJ71C24    | Serial communication module | '14' or later    |
| RJ71C24-R2 |                             |                  |
| RJ71C24-R4 |                             |                  |

### Restricted functions

The following functions have some restrictions applied when using a C24 in a redundant system with a redundant extension base unit.

The other functions can be used without restrictions.

| Function                                 | Restriction                                                                                                                                                                                                                                                                                                                                                                        | Reference                                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Data communication using the MC protocol | When executing a command that manages files, specify the I/O number other than those of the control system (03D0H) and standby system (03D1H).                                                                                                                                                                                                                                     |  MELSEC Communication Protocol Reference Manual |
| MELSOFT connection                       | Specifying a connection destination has some restrictions.<br>When specifying "Not specified", the operation is performed in the same way as when specifying "Control System".<br>Operations involving file writing (such as "Write to PLC") cannot be performed.<br>To perform operations involving file writing, connect an engineering tool via a module on the main base unit. |  GX Works3 Operating Manual                     |

### ■ Considerations

- If the system is switched during the MELSOFT connection, MC protocol communications, or communications using dedicated instructions from other stations, a communication timeout may occur.
- If the system is switched during the simple CPU communications, a CPU response monitoring timer error (7A02H) may occur. Try again as necessary.
- If the system is switched during communications using MODBUS, a CPU response monitoring timer timeout (7380H) may occur. Try again as necessary.

### Dedicated instructions

Dedicated instructions cannot be used.

Mount a serial communication module on the main base unit to use dedicated instructions.

For alternative dedicated instructions in the program using I/O signals, refer to the following section.

 Page 662 Alternative program examples of dedicated instructions

### Module FBs

Module FBs cannot be used.

## Module parameter

- The module extended parameter and predefined protocol setting must be written to the C24, not to the CPU module.
- Data reception with an interrupt program cannot be used. Do not set the item in [Module Parameter] ⇒ [Interrupt Settings].

## Alternative program examples of dedicated instructions

The following shows the programs using I/O signals to alternate dedicated instructions.

### Availability of alternatives using I/O signals

Dedicated instructions which can be replaced with the program using I/O signals are as follows:

○: Available, —: Not available, △: Available with restriction

| Dedicated instruction |                                                                                 | Processing                                                                                                                                                          | Alternative     | Reference                                                                         |
|-----------------------|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------|
| ONDEMAND              | Sending data using the on-demand function                                       | Sends data using the on-demand function of MC protocol.                                                                                                             | ○               | Page 665 Alternative program example of the ONDEMAND instruction                  |

| UINI                  | Switching the mode                                                              | Switches the serial communication module mode, transmission specifications, and self-station number.                                                                | △ <sup>*2</sup> | Page 685 Alternative program example of the UINI instruction                      |

\*1 Transmission processing must be stopped when clearing receive data.

\*2 Station number or operating status (independent/linked) cannot be changed.

System configuration example

- (1) Control system
- (2) Standby system
- (3) Tracking cable
- (4) Extension cable
- (5) RJ71C24 (start I/O number: 0100H)
- (6) External device

Connect the master station of the control system and that of the standby system to a redundant extension base unit with extension cables.

Parameter settings of C24 mounted on a redundant extension base unit

The following shows the parameter settings required to be set in an engineering tool.

Point

In this example, default values are used for parameters that are not shown below.  
Change the module parameter according to the specifications of the target device.

A

1. Select "R08P" for "Type" and "Redundant" for "Mode" to set the CPU module.

[Project] ⇒ [New]

2. Select the model name of a base unit in the system parameter.

[Navigation window] ⇒ [Parameter] ⇒ [System Parameter] ⇒ [Base/Power/Extension Cable Setting]

| Item                               | Description |                     |                  |
|------------------------------------|-------------|---------------------|------------------|
|                                    |             | Base Type           | Base Module Name |
| Base/Power/Extension Cable Setting | Main        | Main Base Unit      | R35B             |
|                                    | Extension 1 | Extension Base Unit | R68WRB           |

3. Set the I/O assignment setting as follows:

[Navigation window] ⇒ [Parameter] ⇒ [System Parameter] ⇒ [I/O Assignment Setting]

| Item                   |             | Description            |          |
|------------------------|-------------|------------------------|----------|
|                        |             | Module Name            | Start XY |
| I/O Assignment Setting | Main        | R08PCPU (Host Station) | 3E00     |
|                        |             | R6RFM                  | 0000     |
|                        | Extension 1 | RJ71C24                | 0100     |

4. Click the [OK] button to add module labels of the RJ71C24.

"Signal Flow Memory Tracking Setting" must be set to "Transfer" (default) in [CPU Parameter] ⇒ [Redundant System Settings] ⇒ [Tracking Setting] ⇒ [Signal Flow Memory Tracking Setting] due to some instructions used in a program, such as PLS instruction.

## Alternative program example of the ONDEMAND instruction

The following shows the program example to send data using the on-demand function of MC protocol.

### ■Overview

An operation overview of sample program is as follows.

The data "12345678" is sent by using the following user frames.

| User frame        | User frame No. | Registered code              | Registered data content                                                                |
|-------------------|----------------|------------------------------|----------------------------------------------------------------------------------------|
| Start frame (1st) | 02H (2)        | 02H                          | Data code from STX to self-station number matched to QnA compatible 3C frame, format 3 |
| Start frame (2nd) | 3EBH (1003)    | F9H, 00H, 00H, FFH, FFH, 00H |                                                                                        |
| Final frame (1st) | 401H (1025)    | 03H, FFH, F1H                | Data code of ETX, sum check code equivalent to QnA compatible 3C frame, format 3       |

The send data is as follows:

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

☞ Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Set the following items for CH1 in the module parameter.

☞ [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item                 | Description                   |                                    |                                                                                   |
|----------------------|-------------------------------|------------------------------------|-----------------------------------------------------------------------------------|
| Basic settings       | Various control specification | Communication protocol setting     | MC protocol (any of "Format 1" to "Format 4")                                     |
|                      |                               | Communication speed setting        | Select other than "Automatically set" according to the communication destination. |
| Application settings | User frame specification      | On demand user frame specification | Start frame No. designation (1st)                                                 |
|                      |                               |                                    | 2H (2)                                                                            |
|                      |                               |                                    | Final frame No. designation (1st)                                                 |
|                      |                               |                                    | 401H (1025)                                                                       |
|                      |                               |                                    | Start frame No. designation (2nd)                                                 |
|                      |                               |                                    | 3EBH (1003)                                                                       |
|                      |                               |                                    | Final frame No. designation (2nd)                                                 |
|                      |                               |                                    | 0 (No specification)                                                              |

3. Set the module extended parameters.

☞ [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Extended Parameter]

| Item                | Description |                            |                                                       |
|---------------------|-------------|----------------------------|-------------------------------------------------------|
| User frame contents | User frame  | Registration frame No.1003 | F90000FFFF00                                          |
|                     |             | Registration frame No.1025 | 03FFF1<br>(Control code: "ETX", Special code: "FFF1") |

4. Write the set parameters to the module.

☞ [Online] ⇒ [Write to PLC]

- When writing module extended parameters, an engineering tool must be connected to the control system.
- Specify "Intelligent Function Module" as the writing destination of module extended parameters.

5. Reset the CPU module or turn the power OFF and ON.

## ■Program example

| Category                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Label name                                     | Description                          | Device |              |                       |           |  |       |                       |   |                  |     |     |              |     |   |              |     |     |              |    |   |                  |     |     |              |    |   |          |     |     |              |    |   |       |     |     |              |    |   |             |                                     |     |              |    |   |             |                                     |     |              |    |   |                       |                                     |     |              |    |   |                 |                                     |     |              |    |    |                 |                                     |     |              |    |

- (0) Executes the program when 'bSendInstruction' turns ON.
- (3) Writes send data to the C24 buffer memory C00H (user setting area).  
Writes the buffer memory address C00H and 2 (send data quantity) to the C24 buffer memory A0H (for designation of on-demand function).
- (23) Turns 'CH1 Transmission request' ON.
- (34) Turns 'bSuccess' ON when 'CH1 Transmission normal completion' turns ON.  
Turns 'bFail' ON and reads the C24 buffer memory 256H (CH1 on-demand execution result) when 'CH1 Transmission abnormal completion' turns ON.
- (46) Turns 'CH1 Transmission request' OFF.

## Alternative program example of the CPRTCL instruction

The following shows the program example to execute the protocol registered in an engineering tool.

### ■Overview

An operation overview of sample program is as follows.

A request message of the command 0401 is sent by using the MC protocol (4C frame, format 4) and data from the target device D100 is read.

The read data is stored in D6.

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Set the following items for CH1 in the module parameter.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item           |                               |                                | Description                                                                       |
|----------------|-------------------------------|--------------------------------|-----------------------------------------------------------------------------------|
| Basic settings | Various control specification | Communication protocol setting | Predefined protocol                                                               |
|                |                               | Communication speed setting    | Select other than "Automatically set" according to the communication destination. |

3. Write the set parameters to the module.

 [Online] ⇒ [Write to PLC]

4. Start the predefined protocol support function from the [Tool] menu of engineering tool.

 [Tool] ⇒ [Predefined Protocol Support Function]

5. Select a target module of the protocol setting data.

6. Create new protocol setting data.

 [File]⇒[New]

7. Add the following protocol in the protocol setting screen of predefined protocol support function.

| Protocol No. | Manufacturer        | Model                           | Protocol Name |
|--------------|---------------------|---------------------------------|---------------|
| 1            | MITSUBISHI ELECTRIC | MC Protocol 4C Frame (Format 4) | 0401:Batch RD |

8. Right-click the added protocol, and select "Device Batch Setting".

9. Enter 'D0' in "Device No." in the "Device Batch Setting" screen.

10. Write the created protocol setting data to C24.

 [Online] ⇒ [Write to Module]

Specify "Intelligent Function Module" for "Target Memory".

If the CPU module is in the backup mode, protocol setting data cannot be written. Be sure to switch the CPU module to the separate mode before writing.

11. Reset the CPU module or turn the power OFF and ON.

## Program example

| Category            | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Description                         | Device |              |                       |           |  |       |                       |   |                   |     |     |              |     |   |                      |     |     |              |    |   |            |     |     |              |    |   |          |            |     |              |    |   |           |                  |     |              |    |   |            |                                     |     |              |    |   |         |                                     |     |              |      |

- (0) Executes the program when 'bStartInstruction' turns ON.
- (6) Sets the device code, start device number, and number of device points to be read.  
Writes '1' to the C24 buffer memory 4000H (CH1 number of consecutive protocol executions).  
Writes '1' to the C24 buffer memory 4004H (CH1 protocol number).  
Turns 'CH1 Protocol execution request' ON.

- (30) Reads the C24 buffer memory 4002H (CH1 data transmission result) when 'Protocol execution completion' turns ON.  
Turns 'CH1 Protocol execution request' OFF.

## Alternative program example of the OUTPUT instruction

The following shows the program to send data in user-specified message format through communications using the nonprocedural protocol.

### ■Overview

An operation overview of sample program is as follows.

The data stored in D11 or later is sent by using the nonprocedural protocol.

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Set the following items for CH1 in the module parameter.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item           |                               |                                | Description                                                                       |
|----------------|-------------------------------|--------------------------------|-----------------------------------------------------------------------------------|
| Basic settings | Various control specification | Communication protocol setting | Nonprocedural protocol                                                            |
|                |                               | Communication speed setting    | Select other than "Automatically set" according to the communication destination. |

3. Write the set parameters to the module.

 [Online] ⇒ [Write to PLC]

4. Reset the CPU module or turn the power OFF and ON.

| Label to be defined | Define the global label as shown below.        |                                      |            |
|                     | Label Name                                     | Data Type                            | Class      |
| 1                   | bSendInstruction                               | Bit                                  | VAR_GLOBAL |
| 2                   | uSendData_1                                    | String(32)                           | VAR_GLOBAL |
| 3                   | uSendData_2                                    | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL |
| 4                   | uSendDataNum                                   | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL |
| 5                   | uSendErrCode                                   | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL |

- (0) Sets the send data, end code, and send data quantity.  
Writes the above items to the C24 buffer memory 400H (send/receive area).  
Turns 'CH1 Transmission request' ON.
- (27) Turns 'CH1 Transmission request' OFF when 'CH1 Transmission normal completion' turns ON.
- (29) Reads the C24 buffer memory 257H (CH1 data transmission result) when 'CH1 Transmission abnormal completion' turns ON.  
Turns 'CH1 Transmission request' OFF.

Alternative program example of the INPUT instruction

The following shows the program example to receive data in user-specified message format through communications using the nonprocedural protocol.

Overview

An operation overview of sample program is as follows.  
The data received from a target device is stored in D1 or later by using the nonprocedural protocol.

Parameter settings

Set parameters in an engineering tool as follows:

- 1. Set the following parameters.  
 Page 663 Parameter settings of C24 mounted on a redundant extension base unit
- 2. Set the following items for CH1 in the module parameter.  
 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item           |                               |                                | Description                                                                       |
|----------------|-------------------------------|--------------------------------|-----------------------------------------------------------------------------------|
| Basic settings | Various control specification | Communication protocol setting | Nonprocedural protocol                                                            |
|                |                               | Communication speed setting    | Select other than "Automatically set" according to the communication destination. |

- 3. Write the set parameters to the module.  
 [Online] ⇒ [Write to PLC]
- 4. Reset the CPU module or turn the power OFF and ON.

## Program example

| Category            | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Description                         | Device |            |                       |           |  |       |                       |   |              |                                     |     |            |      |   |           |                                     |     |            |      |   |             |                                     |     |            |         |

- (0) Reads the C24 buffer memory 600H (CH1 receive data quantity) and 601H (CH1 receive data) when data is received.
- (14) Reads the C24 buffer memory 258H (CH1 data reception result) when abnormal reception is detected.
- (22) Turns 'CH1 Reception data read completion' ON when data is received or abnormal reception is detected.

A

## Alternative program example of the BIDOUT instruction

The following shows the program example to send data for the designated data count using the bidirectional protocol.

### ■Overview

An operation overview of sample program is as follows.

The data stored in D11 or later is sent by using the bidirectional protocol.

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Set the following items for CH1 in the module parameter.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item           |                               |                                | Description                                                                       |
|----------------|-------------------------------|--------------------------------|-----------------------------------------------------------------------------------|
| Basic settings | Various control specification | Communication protocol setting | Bidirectional protocol                                                            |
|                |                               | Communication speed setting    | Select other than "Automatically set" according to the communication destination. |

3. Write the set parameters to the module.

 [Online] ⇒ [Write to PLC]

4. Reset the CPU module or turn the power OFF and ON.

### ■Program example

 Page 671 Program example

## Alternative program example of the BIDIN instruction

The following shows the program example to receive data using the bidirectional protocol.

### ■Overview

An operation overview of sample program is as follows.

The data received from a target device is stored in D1 or later by using the bidirectional protocol.

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Set the following items for CH1 in the module parameter.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item           |                               |                                | Description                                                                       |
|----------------|-------------------------------|--------------------------------|-----------------------------------------------------------------------------------|
| Basic settings | Various control specification | Communication protocol setting | Bidirectional protocol                                                            |
|                |                               | Communication speed setting    | Select other than "Automatically set" according to the communication destination. |

3. Write the set parameters to the module.

 [Online] ⇒ [Write to PLC]

4. Reset the CPU module or turn the power OFF and ON.

## Program example

| Category            | Label name                                    | Description                         | Device     |

| Label to be defined | Define the global label as shown below.       |                                     |            |
|                     | Label Name                                    | Data Type                           | Class      |
| 1                   | uRecvDataNum                                  | Word [Unsigned]/Bit String [16-bit] | VAR_GLOBAL |
| 2                   | uRecvData                                     | Word [Unsigned]/Bit String [16-bit] | VAR_GLOBAL |
| 3                   | uRecvErrCode                                  | Word [Unsigned]/Bit String [16-bit] | VAR_GLOBAL |

- (0) Reads the C24 buffer memory 600H (CH1 receive data quantity), 601H (CH1 receive data), and 258H (CH1 data reception result) when data is received. Turns 'CH1 Reception data read completion' ON.

## Alternative program example of the PRR instruction

The following shows the program example to send data with a user frame using the nonprocedural protocol (according to the contents defined in the send user frame designation area).

### Overview

An operation overview of sample program is as follows.

Data is sent by using the following user frames.

| User frame                       | User frame No. | Registered code              | Registered data content                                         |
|----------------------------------|----------------|------------------------------|-----------------------------------------------------------------|
| Send frame No. designation (1st) | 3F2H(1010)     | 02H, 51H, 0AH, FFH, 01H, 3BH | [STX], "Q", Station No. of target device, Self-station No., "," |
| Send frame No. designation (2nd) | 3F3H(1011)     | 54H, 4FH, 54H, 41H, 4CH, 3BH | "TOTAL;,"                                                       |
| Send frame No. designation (3rd) | 8001H(32769)   | 2DH, 01H                     | Arbitrary data (021DH)                                          |
| Send frame No. designation (4th) | 8000H(32768)   | 34H, 12H, ABH, 56H           | Arbitrary data in send area (1234H, 56ABH)                      |
| Send frame No. designation (5th) | 41BH(1051)     | 03H, FFH, F0H                | Data code of [ETX], sum check code                              |

The send data is as follows:

## ■Parameter settings

Set parameters in an engineering tool as follows:

### 1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

### 2. Set the following items for CH1 in the module parameter.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item                 |                               |                                |                                  | Description                                                                       |
|----------------------|-------------------------------|--------------------------------|----------------------------------|-----------------------------------------------------------------------------------|
| Basic settings       | Various control specification | Communication protocol setting |                                  | Nonprocedural protocol                                                            |
|                      |                               | Communication speed setting    |                                  | Select other than "Automatically set" according to the communication destination. |
|                      |                               | Transmission setting           | Data bit                         | 8                                                                                 |
| Application settings | User frame specification      | Send user frame designation    | Output start pointer designation | 1                                                                                 |
|                      |                               |                                | Output quantity designation      | 5                                                                                 |
|                      |                               |                                | Send frame No. designation (1st) | 3F2H(1010)                                                                        |
|                      |                               |                                | Send frame No. designation (2nd) | 3F3H(1011)                                                                        |
|                      |                               |                                | Send frame No. designation (3rd) | 8001H(32769)                                                                      |
|                      |                               |                                | Send frame No. designation (4th) | 8000H(32768)                                                                      |
|                      |                               |                                | Send frame No. designation (5th) | 41BH(1051)                                                                        |

### 3. Set the module extended parameters.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Extended Parameter]

| Item                |            |                            |  | Description                                           |
|---------------------|------------|----------------------------|--|-------------------------------------------------------|
| User frame contents | User frame | Registration frame No.1010 |  | 02510AFF013B                                          |
|                     |            | Registration frame No.1011 |  | 544F54414C3B                                          |
|                     |            | Registration frame No.1051 |  | 03FFF0<br>(Control code: "ETX", Special code: "FFF0") |

### 4. Write the set parameters to the module.

 [Online] ⇒ [Write to PLC]

- When writing module extended parameters, an engineering tool must be connected to the control system.
- Specify "Intelligent Function Module" as the writing destination of module extended parameters.

### 5. Reset the CPU module or turn the power OFF and ON.

## ■Program example

| Category            | Label name                                     | Description                          | Device                      |
|---------------------|------------------------------------------------|--------------------------------------|-----------------------------|
| Module label        | C24_1.uIO                                      | Start I/O No.                        | —                           |
|                     | C24_1.stnCH1.bSts_TransmissionNormalCompletion | CH1 Transmission normal completion   | X100                        |
|                     | C24_1.stnCH1.bSts_TransmissionAbnormalEnd      | CH1 Transmission abnormal completion | X101                        |
|                     | C24_1.bSts_UnitReady                           | Module READY                         | X11E                        |
|                     | C24_1.bSts_WatchdogTimerError                  | Watchdog timer error                 | X11F                        |
|                     | C24_1.stnCH1.bSet_Req_Transmission             | CH1 Transmission request             | Y100                        |
| Label to be defined | Define the global label as shown below.        |                                      |                             |
|                     | Label Name                                     | Data Type                            | Class Assign (Device/Label) |
| 1                   | bSendInstruction                               | Bit                                  | VAR_GLOBAL x50              |
| 2                   | bSendInstructionPulse                          | Bit                                  | VAR_GLOBAL M50              |
| 3                   | uErrCode                                       | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL D20              |
| 4                   | uSendDataCount                                 | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL D0               |
| 5                   | uSendData_1                                    | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL D1               |
| 6                   | uSendData_2                                    | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL D2               |
| 7                   | u8001DataCount                                 | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL D3               |
| 8                   | u8001Data                                      | Word [Unsigned]/Bit String [16-bit]  | VAR_GLOBAL D4               |

- (0) Executes the program when 'bSendInstruction' turns ON.
- (3) Writes send data to the C24 buffer memory 400H (send/receive area).  
Writes the user frame No.8001H to the C24 buffer memory 1B00H (for user registration).  
Turns 'CH1 Transmission request' ON.
- (30) Turns 'CH1 Transmission request' OFF when 'Transmission normal completion' turns ON.
- (32) Reads the C24 buffer memory 257H (data transmission result) when 'Transmission abnormal completion' turns ON.  
Turns 'CH1 Transmission request' OFF.

Alternative program example of the CSET instruction (receive data clear)

The following shows the program example to clear receive data using the nonprocedural protocol.

Overview

An operation overview of sample program is as follows.  
Receive data is cleared for the OS area of the C24 by using the nonprocedural protocol.

Point

- Do not execute a clear request of receive data during data transmission. Otherwise, the data transmission is canceled.
- Resume data communication with a target device after the receive data clear processing with C24 is completed.

Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.
- Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Set the following items for CH1 in the module parameter.
- [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Parameter]

| Item           |                               |                                | Description                                                                       |
|----------------|-------------------------------|--------------------------------|-----------------------------------------------------------------------------------|
| Basic settings | Various control specification | Communication protocol setting | Nonprocedural protocol                                                            |
|                |                               | Communication speed setting    | Select other than "Automatically set" according to the communication destination. |

3. Write the set parameters to the module.
- [Online] ⇒ [Write to PLC]
4. Reset the CPU module or turn the power OFF and ON.

## Program example

| Category            | Label name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Description                         | Device |              |                       |           |  |       |                       |   |                 |     |     |              |     |   |                 |     |     |              |     |   |                        |     |     |              |     |   |                           |     |     |              |     |   |                           |     |     |              |     |   |            |     |     |              |     |   |                              |     |     |              |     |   |                     |                                     |     |              |    |

- (0) Executes the program when 'X50' turns ON.
- (5) Writes '1' (requested) to the C24 buffer memory 0A8H (receive data clear request) when 'data clear request acknowledgement flag' turns ON.
- (19) Reads the C24 buffer memory 0A8H (receive data clear status) when 'data clear request completion flag' turns ON. Turns 'data clear request completion flag' OFF when the receive data status is '0' (not requested).
- (32) When 'data clear request acknowledgement flag' and 'data clear request completion flag' are turned OFF, data communication becomes available.

## Alternative program example of the CSET instruction (initial setting)

The following shows the program example to set the send/receive data quantity unit (word/byte) and data send/receive area.

### ■Overview

An operation overview of sample program is as follows.

The following items for CH1 are set.

| Item                                                                 | Description |
|----------------------------------------------------------------------|-------------|
| Send/receive data quantity unit (word/byte)                          | Word unit   |
| On-demand function buffer memory start address                       | 400H        |
| On-demand function buffer memory size                                | 10H         |
| Sending area start address for nonprocedural/bidirectional protocols | C00H        |
| Nonprocedural/bidirectional protocols sending area size              | 100H        |
| Nonprocedural/bidirectional protocols receiving area start address   | D00H        |
| Nonprocedural/bidirectional protocols receiving area size            | 300H        |

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Write the set parameters to the module.

 [Online] ⇄ [Write to PLC]

3. Reset the CPU module or turn the power OFF and ON.

## ■Program example

| Category            | Label name                                                                                                                                                                                                                                                                                                                                                                                                                    | Description                         | Device |              |                       |           |  |       |                       |   |               |                                     |     |              |    |   |       |                                     |     |              |    |

- (0) Writes '1' (word unit) to the C24 buffer memory 96H (CH1 word/byte units designation).
- (8) Writes 400H to the C24 buffer memory A0H (CH1 on-demand function buffer memory start address designation) and 10H to A1H (CH1 on-demand function data length designation).
- (22) Writes C00H to the C24 buffer memory A2H (CH1 send buffer memory start address designation) and 100H to A3H (CH1 send buffer memory length designation).
- (36) Writes D00H to the C24 buffer memory A6H (CH1 receiving buffer memory start address designation) and 300H to A7H (CH1 receive buffer memory length designation).

## Alternative program example of the PUTE instruction

The following shows the program example to register a user frame.

### ■Overview

An operation overview of sample program is as follows.

F9H, 00H, 00H, FFH, FFH, and 00H are registered in the user frame No.3EBH (1003).

### ■Parameter settings

Set parameters in an engineering tool as follows:

1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

2. Write the set parameters to the module.

 [Online] ⇄ [Write to PLC]

3. Reset the CPU module or turn the power OFF and ON.

- (0) Executes the program when 'X50' turns ON.
- (4) Writes to the C24 buffer memory 2H (register/read/delete instructions), 3H (frame No. direction), 5H (number of registered data bytes), and 6H (user frame).
- (28) Turns 'User frame write request to flash ROM' ON.  
 Reads the C24 buffer memory 4H (register/read/delete results) and turns 'User frame write request to flash ROM' OFF at the completion of writing.

## Alternative program example of the GETE instruction

The following shows the program example to read a user frame.

### ■Overview

The user frame No.3EBH (1003) is read.

### ■Parameter settings

Set parameters in an engineering tool as follows:

#### 1. Set the following parameters.

 Page 663 Parameter settings of C24 mounted on a redundant extension base unit

#### 2. Set the module extended parameters.

 [Navigation window] ⇒ [Parameter] ⇒ [Module Information] ⇒ [RJ71C24] ⇒ [Module Extended Parameter]

| Item                |            |                            | Description  |
|---------------------|------------|----------------------------|--------------|
| User frame contents | User frame | Registration frame No.1003 | F90000FFFF00 |

#### 3. Write the set parameters to the module.

 [Online] ⇒ [Write to PLC]

- When writing module extended parameters, an engineering tool must be connected to the control system.
- Specify "Intelligent Function Module" as the writing destination of module extended parameters.

#### 4. Reset the CPU module or turn the power OFF and ON.

- (0) Executes the program when 'X50' turns ON.
- (4) Writes to the C24 buffer memory 2H (register/read/delete instructions) and 3H (frame No. direction).
- (17) Turns 'User frame read request to flash ROM' ON.  
 Reads the C24 buffer memory 4H (register/read/delete results) and turns 'User frame read request from flash ROM' OFF at the completion of reading.  
 Reads the C24 buffer memory 5H (registration data byte count designation) if the read result is '0' (normal completion).  
 Calculates the number of words of registration data for FROM instruction.  
 Reads the C24 buffer memory 6H (user frame).

## Alternative program example of the UINI instruction

For the program examples of switching serial communication module mode and transmission specifications, refer to the following section.

Page 415 Mode Switching Method by Program

# Appendix 10 Added and Changed Functions

This section shows the added and changed functions of C24.

| Added/changed contents                                                                                                                                                                                                                                                              | Software version of an engineering tool | Firmware version | Reference                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|------------------|-----------------------------------------------------------------------------------------------------------------|
| A redundant system is supported for remote head modules.                                                                                                                                                                                                                            | —                                       | '07' or later    | —                                                                                                               |
| The MODBUS slave function is supported.                                                                                                                                                                                                                                             | —                                       | '11' or later    | Page 112 MODBUS Slave Function                                                                                  |
| The following function is supported by the predefined protocol function: <ul style="list-style-type: none"><li>• Redundant system</li></ul>                                                                                                                                         | —                                       | '13' or later    | —                                                                                                               |
| The following functions are supported by the MODBUS slave function: <ul style="list-style-type: none"><li>• Redundant system</li><li>• Interlink operation</li><li>• Mode switching using the dedicated instruction (UINI)</li><li>• Mode switching using the MC protocol</li></ul> |                                         |                  | Page 112 MODBUS Slave Function<br>Page 409 SWITCHING THE MODE AFTER STARTING<br>Page 580 Dedicated Instructions |
| The following function is supported by the MODBUS slave function: <ul style="list-style-type: none"><li>• Access target specification for a CC-Link IE Field Network remote head module</li></ul>                                                                                   |                                         |                  | Page 112 MODBUS Slave Function                                                                                  |
| The simple CPU communication function is supported. <ul style="list-style-type: none"><li>• Supported model: RJ71C24*<sup>1</sup>, RJ71C24-R2</li><li>• Communication destination: MELSEC-A/AnS (CPU COM)</li></ul>                                                                 |                                         |                  | Page 118 DATA COMMUNICATION IN SIMPLE CPU COMMUNICATION                                                         |
| A redundant extension base unit is supported.                                                                                                                                                                                                                                       | '1.070Y' or later                       | '14' or later    | Page 661 Using the Module in the Redundant System with Redundant Extension Base Unit                            |
| The simple CPU communication function is supported. <ul style="list-style-type: none"><li>• Supported model: RJ71C24(CH2), RJ71C24-R4</li></ul>                                                                                                                                     | '1.075D' or later                       | '15' or later    | Page 118 DATA COMMUNICATION IN SIMPLE CPU COMMUNICATION                                                         |
| The following communication destinations are supported by the simple CPU communication function: <ul style="list-style-type: none"><li>• MODBUS (RTU)-compatible device</li><li>• MODBUS (ASCII)-compatible device</li></ul>                                                        |                                         |                  |                                                                                                                 |
| Write single register (FC: 06H) of the MODBUS standard function is supported by the simple CPU communication function.                                                                                                                                                              | —                                       | '21' or later    | Page 120 Communication with a MODBUS Slave Device                                                               |
| Operations when an error occurs for multiple settings in the simple CPU communication function are changed.                                                                                                                                                                         |                                         |                  | Page 125 Operations when an error occurs for multiple settings                                                  |

\*1 Only CH1 (RS-232) is supported.

# WARRANTY

---

Please confirm the following product warranty details before using this product.

## **1. Gratis Warranty Term and Gratis Warranty Range**

If any faults or defects (hereinafter "Failure") found to be the responsibility of Mitsubishi occurs during use of the product within the gratis warranty term, the product shall be repaired at no cost via the sales representative or Mitsubishi Service Company.

However, if repairs are required onsite at domestic or overseas location, expenses to send an engineer will be solely at the customer's discretion. Mitsubishi shall not be held responsible for any re-commissioning, maintenance, or testing on-site that involves replacement of the failed module.

[Gratis Warranty Term]

The gratis warranty term of the product shall be for one year after the date of purchase or delivery to a designated place. Note that after manufacture and shipment from Mitsubishi, the maximum distribution period shall be six (6) months, and the longest gratis warranty term after manufacturing shall be eighteen (18) months. The gratis warranty term of repair parts shall not exceed the gratis warranty term before repairs.

[Gratis Warranty Range]

- (1) The range shall be limited to normal use within the usage state, usage methods and usage environment, etc., which follow the conditions and precautions, etc., given in the instruction manual, user's manual and caution labels on the product.
- (2) Even within the gratis warranty term, repairs shall be charged for in the following cases.
  1. Failure occurring from inappropriate storage or handling, carelessness or negligence by the user. Failure caused by the user's hardware or software design.
  2. Failure caused by unapproved modifications, etc., to the product by the user.
  3. When the Mitsubishi product is assembled into a user's device, Failure that could have been avoided if functions or structures, judged as necessary in the legal safety measures the user's device is subject to or as necessary by industry standards, had been provided.
  4. Failure that could have been avoided if consumable parts (battery, backlight, fuse, etc.) designated in the instruction manual had been correctly serviced or replaced.
  5. Failure caused by external irresistible forces such as fires or abnormal voltages, and Failure caused by force majeure such as earthquakes, lightning, wind and water damage.
  6. Failure caused by reasons unpredictable by scientific technology standards at time of shipment from Mitsubishi.
  7. Any other failure found not to be the responsibility of Mitsubishi or that admitted not to be so by the user.

## **2. Onerous repair term after discontinuation of production**

- (1) Mitsubishi shall accept onerous product repairs for seven (7) years after production of the product is discontinued. Discontinuation of production shall be notified with Mitsubishi Technical Bulletins, etc.
- (2) Product supply (including repair parts) is not available after production is discontinued.

## **3. Overseas service**

Overseas, repairs shall be accepted by Mitsubishi's local overseas FA Center. Note that the repair conditions at each FA Center may differ.

## **4. Exclusion of loss in opportunity and secondary loss from warranty liability**

Regardless of the gratis warranty term, Mitsubishi shall not be liable for compensation to:

- (1) Damages caused by any cause found not to be the responsibility of Mitsubishi.
- (2) Loss in opportunity, lost profits incurred to the user by Failures of Mitsubishi products.
- (3) Special damages and secondary damages whether foreseeable or not, compensation for accidents, and compensation for damages to products other than Mitsubishi products.
- (4) Replacement by the user, maintenance of on-site equipment, start-up test run and other tasks.

## **5. Changes in product specifications**

The specifications given in the catalogs, manuals or technical documents are subject to change without prior notice.
